OMAP36xx Multimedia Device Silicon Revision 1.x

Texas Instruments OMAP™ Family of Products

Version J

Technical Reference Manual

Literature Number: SWPU177J
December 2009–Revised August 2010

WARNING: EXPORT NOTICE

Recipient agrees to not knowingly export or re-export, directly or indirectly, any product or technical data (as defined by the U.S., EU, and other Export Administration Regulations) including software, or any controlled product restricted by other applicable national regulations, received from Disclosing party under this Agreement, or any direct product of such technology, to any destination to which such export or re-export is restricted or prohibited by U.S. or other applicable laws, without obtaining prior authorisation from U.S. Department of Commerce and other competent Government authorities to the extent required by those laws. This provision shall survive termination or expiration of this Agreement.

According to our best knowledge of the state and end-use of this product or technology, and in compliance with the export control regulations of dual-use goods in force in the origin and exporting countries, this technology is classified as follows:

US ECCN: 3E991

EU ECCN: EAR99

And may require export or re-export license for shipping it in compliance with the applicable regulations of certain countries.

Survey

Help us meet your expectations:

We are always looking at ways to develop our service and improve our quality to fit your needs. Please take a few minutes to complete our short questionnaire by:

- Providing general suggestions
  or
- Rating a document and describing its critical points

About This Manual

FCC Warning

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

Information About Cautions and Warnings

This book may contain cautions and warnings.

CAUTION

This is an example of a caution statement.

A caution statement describes a situation that could potentially damage your software or equipment.

WARNING

This is an example of a warning statement.

A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.

Register, Field, and Bit Calls

The naming convention applied for a call consists of:

- For a register call: *<Module name>.<Register name>*; for example: UART.UASR
- For a bit field call:
  - *<Module name>.<Register name>[End:Start] <Field name> field*; for example, UART.UASR[4:0] SPEED bit field
  - *<Field name> field <Module name>.<Register name>[End:Start]*; for example, SPEED bit field UART.UASR[4:0]
- For a bit call:
  - *<Module name>.<Register name>[pos] <Bit name> bit*; for example, UART.UASR[5] BIT_BY_CHAR bit
  - *<Bit name> bit <Module name>.<Register name>[pos]*; for example, BIT_BY_CHAR bit UART.UASR[5]

To help the reader navigate the document, each register call is hyperlinked to its register description in the register manual section. After each register description, a table summarizes all hyperlinked register calls.

To navigate in the PDF documents, see Acrobat Reader Tips.

Coding Rules

The programming models or code listings follow the rules:

Type	Definition	Example
File	Starts with the module name	PRCM_test1.c MCBSP1_init.h
Variable	Global variables are prefixed by "g_" Pointers are prefixed by "p" Global pointers are prefixed by "g_p"	g_SDMA_LogicalChan pAddrCounter g_pSDMA_LogicalChan
Function	Starts with the module name	PRCM_SetupClocks() ArmIntC_MaskInterrupts()
Typedef	Ends with "_t"	PRCM_Struct_t
Definition	Starts with the module name and is followed by the register name	#define SMS_ERR_TYPE *((volatileUint32*)0x680080F4) #define MCBSP2_RCR1_REG *((volatile Uint32*)0x4807401C)
Enumeration	Starta with the module name	Typedef enum DMA_Mode_Label { INPUT_MODE OUTPUT_MODE } DMA_Mode_t;

Flow Chart Rules

Flow charts follow the following rules:

Shape	Name	Definition
	Process	Any computational steps or processing function of a program; defined operation(s) causing change in value, form, or location of information
	Decision	A decision or switching type operation that determines which of a number of alternate paths is followed
	Predefined process or sub-process	One or more named operations or program steps specified in a subroutine or another set of flow charts
	Data or I/O	General I/O function; information available for processing (input) or recording of processed information (output)
	Terminator	Terminal point in a flow chart: start, stop, halt, delay, or interrupt; may show exit from a closed subroutine
	Annotation	Additional descriptive clarification, comment
	On page connector (reference)	Exit to, or entry from, another part of chart in the same page
	Off page connector (reference)	The flow continues on a different page.
	Summing Junction	Logical AND
	Or	Logical OR
	Parallel mode (ISO)	Beginning or end of two or more simultaneous operations
	Flow Line	Lines indicate the sequence of steps and the direction of flow.

Acrobat Reader Tips

Acrobat includes two methods to search for words in a PDF:

- The Find toolbar provides a basic set of options to locate a word in the current PDF.
- The Search window lista words or partial words that match your text in the current PDF.

These guidelines apply to Acrobat Reader 5.x, 6.0, and 7.0.

For more information on Acrobat Reader search features, see the Adobe Reader Help.

To search for words in a document using the Find dialog box:

1. Open the document.
2. To display the Find toolbar, right-click in the toolbar area and select Find.
3. In the Find box, type the word, words, or partial words for which you want to search.
4. From the Find Options menu, select options as desired.
5. To view each search result, click the Find toolbar, the Find Previous button, or the Find Next button to go backward or forward through the document.

To search for words in a document using the Search PDF window:

1. Open the document.
2. Click the Search button on the File toolbar or right-click on your document and select Search.
3. Type the word, words, or part of a word for which you want to search.
4. Click Search.
5. The results appear in page order and, if applicable, show a few words of context. Each result displays an icon to identify the type of occurrence. All other searchable areas display the Search Result icon.
6. To display the page that contains a search result, click an item in the Results list. The occurrence is highlighted.
7. To navigate to the next result, choose Edit > Search Results > Next Result (or Ctrl+G).
8. To navigate to the previous result, choose Edit > Search Results > Previous Result (or Shift+Ctrl+G).

Navigate through your previous view

To retrace your path within an Adobe PDF document:

- For the previous view: Choose View > Go To > Previous View or Alt+Left Arrow.
- For the next view: Choose View > Go To > Next View or Alt+Right Arrow. The Next View command is available only if you have chosen Previous View.

  If you view the PDF document in a browser, use options on the Navigation toolbar to move between views.

  - Right-click the toolbar area, and then choose *Navigation*.
  - Click the Go To Previous View button or the Go To Next View button.

NOTE: This navigation tip is useful to return to your previous view after clicking on a register call hyperlink.

OMAP36xx Disclaimer

All programming models and use cases presented in this manual are provided for educative purposes only and may differ from or be optimized for your applications.

All OMAP peripheral devices presented in this manual are provided for illustration purposes and may be different from those in your system.

OMAP36xx MIPI® Disclaimer

The material contained herein is not a license, either expressly or impliedly, to any IPR owned or controlled by any of the authors or developers of this material or MIPI. History

The following table summarizes the OMAP36xx TRM versions.

Version	Literature Number	Date	Notes
B	SWPU177	December 2009	See (1)
C	SWPU177	January 2010	See (2)
D	SWPU177	February 2010	See (3)
E	SWPU177	March 2010	See (4)
F	SWPU177	April 2010	See (5)

(1) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.0 Technical Reference Manual* - Initial release (SWPU177B)

(2) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.0 Technical Reference Manual* - version C (SWPU177). Chapters impacted by changes between version B and version C:
- Chapter 1: Introduction
- Chapter 3: Power, Reset, and Clock Management
- Chapter 6: Camera ISP
- Chapter 7: Display Subsystem
- Chapter 9: Interconnect
- Chapter 13: System Control Module
- Chapter 19: UART/IrDA/CIR
- Chapter 21: Multichannel Buffered Serial Port
- Chapter 22: High-Speed USB Host Subsytem and High-Speed USB OTG Controller
- Chapter 26: Initialization

(3) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.0 Technical Reference Manual* - version D (SWPU177). Chapters impacted by changes between version C and version D:
- Chapter 3: Power, Reset, and Clock Management
- Chapter 5: IVA2.2 Subsystem
- Chapter 6: Camera ISP
- Chapter 7: Display Subsystem
- Chapter 10: Memory Subsystem
- Chapter 11: SDMA
- Chapter 13: System Control Module
- Chapter 19: UART/IrDA/CIR
- Chapter 22: High-Speed USB Host Subsytem and High-Speed USB OTG Controller
- Chapter 26: Initialization
- Added Appendix A: OMAP36x1 Multimedia Devices

(4) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.1 Technical Reference Manual* - version E (SWPU177). Chapters impacted by changes between version D and version E:
- Chapter 1: Introduction
- Chapter 3: Power, Reset, and Clock Management
- Chapter 6: Camera ISP
- Chapter 7: Display Subsystem
- Chapter 11: SDMA
- Chapter 13: System Control Module
- Chapter 16: Timers
- Chapter 22: High-Speed USB Host Subsystem and High-Speed USB OTG Controller
- Chapter 26: Initialization
- Appendix A: OMAP3621 Multimedia Device

(5) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.1 Technical Reference Manual* - version F (SWPU177). Chapters impacted by changes between version E and version F:
- Chapter 3: Power, Reset, and Clock Management
- Chapter 4: MPU Subsystem
- Chapter 7: Display Subsystem
- Chapter 10: Memory Subsystem
- Chapter 13: System Control Module
- Chapter 22: High-Speed USB Host Subsystem and High-Speed USB OTG Controller
- Chapter 26: Initialization
- Appendix A: OMAP3621 Multimedia Device

Version	Literature Number	Date	Notes
G	SWPU177	May 2010	See (6)
H	SWPU177	June 2010	See (7)
I	SWPU177	July 2010	See (8)
J	SWPU177	August 2010	See (9)

(6) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.1 Technical Reference Manual* version G (SWPU177). Chapters impacted by changes between version F and version G:
- Chapter 1: Introduction
- Chapter 3: Power, Reset, and Clock Management
- Chapter 6: Camera Image Signal Processor
- Cahtper7: Display Subsystem
- Chapter 8: 2D/3D Graphics Accelerator
- Chapter 11: SDMA
- Chapter 13: System Control Module
- Chpater 17: I2C
- Chapter 20: Multichannel SPI
- Chapter 26: Initialization
- Appendix A: OMAP3621 Multimedia Devices

(7) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.x Technical Reference Manual* version H (SWPU177). Chapters impacted by changes between version G and version H:
- Chapter 1: Introduction
- Chapter 3: Power, Reset, and Clock Management
- Chapter 6: Camera Image Signal Processor
- Chapter 9: Interconnect
- Chpater 19: UART/IrDA/CIR
- Chapter 20: Multichannel SPI
- Chapter 21: Multichannel Buffered Serial Port
- Chapter 26: Initialization
- Appendix A: OMAP3621 Multimedia Devices

(8) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.x Technical Reference Manual* version I (SWPU177). Chapters impacted by changes between version H and version I:
- Chapter 1: Introduction
- Chapter 2: MemoryMapping
- Chapter 3: Power, Reset, and Clock Management
- Chapter 6: Camera Image Signal Processor
- Chapter 7: Display Subsystem
- Chpater 10: Memory Subsystem
- Chapter 21: Multichannel Buffered Serial Port
- Chapter 26: Initialization

(9) Public Version of *OMAP36xx Multimedia Device Silicon Revision 1.x Technical Reference Manual* version J (SWPU177). Chapters impacted by changes between version I and version J:
- Chapter 3: Power, Reset, and Clock Management
- Chapter 7: Display Subsystem
- Chapter 9: Interconnect
- Chapter 13: System Control Module
- Chapter 22: High-Speed USB Host Subsystem and High-Speed USB OTG Controller
- Chapter 26: Initialization

Introduction

This chapter introduces the features, supporting subsystems, and architecture of the OMAP36xx high-performance multimedia devices.

NOTE: This document is strictly for wireless/cellular software developers using OMAP3630 application processors, which are not available for the broad market through authorized distributors.

Topic **Page**

1.1 Overview

The OMAP36xx high-performance, multimedia application device is based on the enhanced OMAP™ 3 architecture and is integrated on TI advanced 45-nm process technology.

This TRM describes all the features available in the OMAP3630, OMAP3621, and OMAP3611 devices. For more information, see Section 1.5, *OMAP36xx Family*.

The architecture is designed to provide best-in-class video, image, and graphics processing sufficient to support the following:

- Streaming video
- 2-dimension/3-dimension (2D/3D) mobile gaming
- Video conferencing
- High-resolution still image
- Video capture in 2.5G wireless terminals, 3G wireless terminals, rich multimedia-featured handsets, and high-performance personal digital assistants (PDAs)

The device supports high-level operating systems (OSs) such as:

- Windows™ CE
- Symbian OS™
- Linux®
- Android OS

This OMAP device includes state-of-the-art power-management techniques required for high-performance mobile products.

The following subsystems are part of the device:

- Microprocessor unit (MPU) subsystem based on the ARM Cortex™-A8 microprocessor
- Imaging video and audio (IVA2.2) subsystem with a TMS320C64x™ digital signal processor (DSP) core
- POWERVR® SGX530 subsystem for 2D and 3D graphics acceleration to support display and gaming effects
- Camera image signal processor (ISP2P) that supports multiple formats and interfacing options to a wide variety of image sensors
- Display subsystem with a wide variety of features for multiple concurrent image manipulation, and a programmable interface supporting a wide variety of displays. The display subsystem also supports NTSC/PAL video out.
- Level 3 (L3) and level 4 (L4) interconnects that provide high-bandwidth data transfers for multiple initiators to the internal and external memory controllers and to on-chip peripherals

The device also offers:

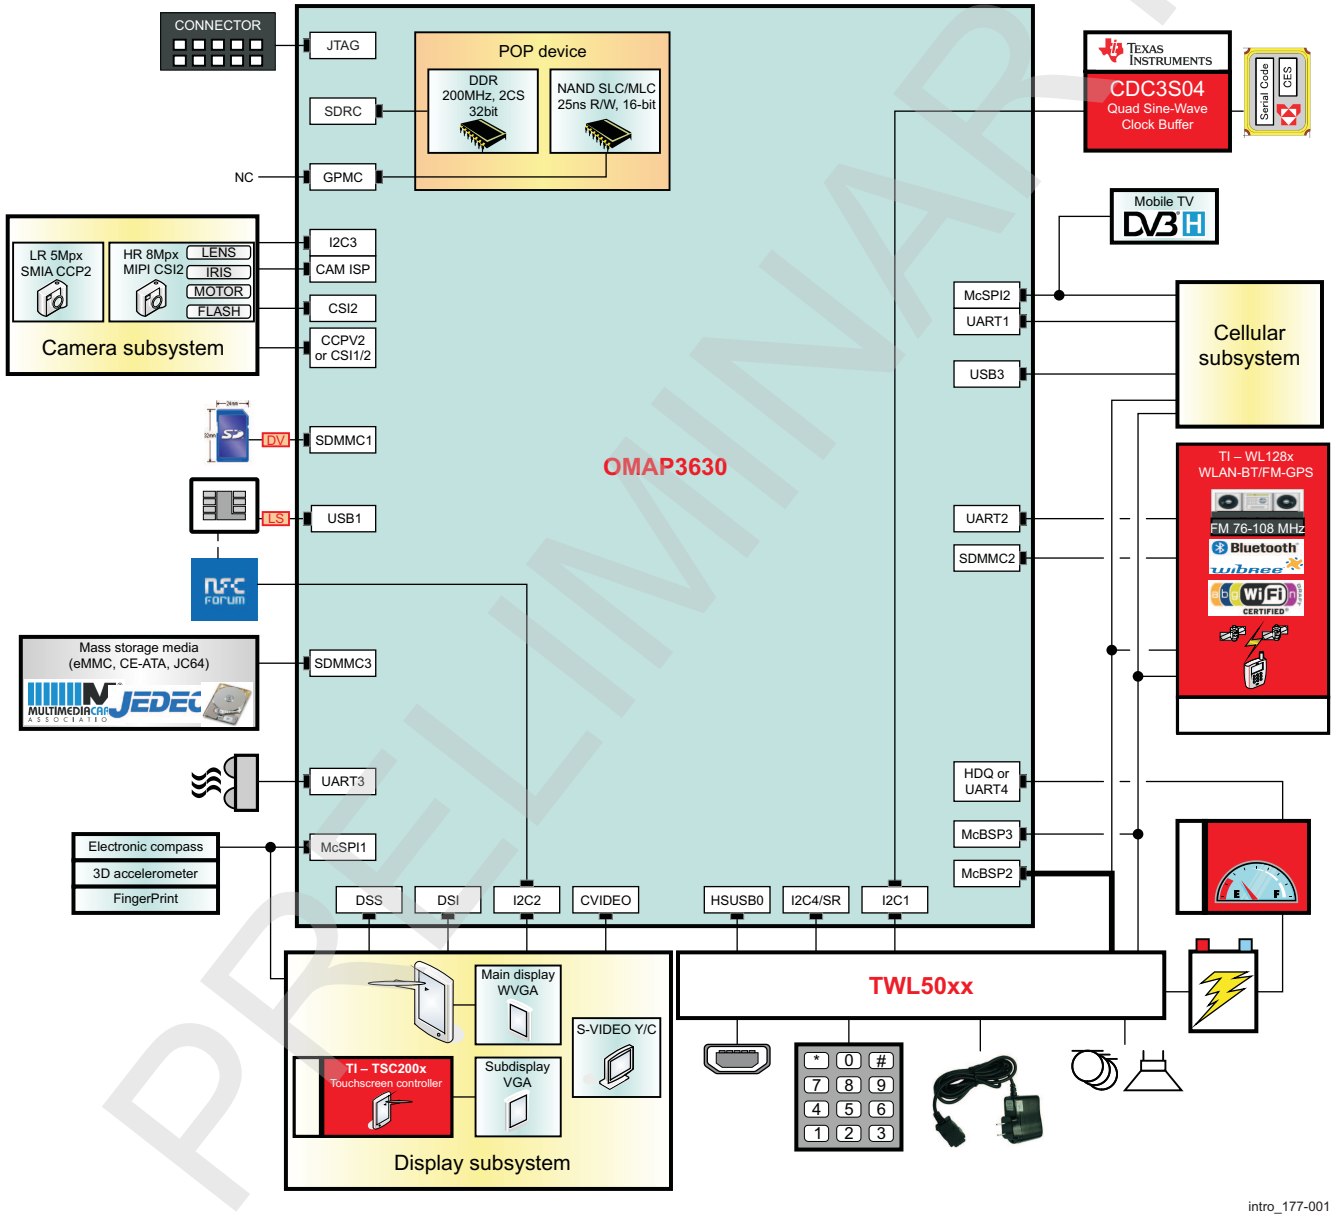
- A comprehensive power and clock-management scheme that enables high-performance, low-power operation, and ultralow-power standby features. The device also supports SmartReflex™ adaptative voltage control. This power-management technique for automatic control of the operating voltage of a module reduces the active power consumption.
- Connectivity to various cellular modem chipset
- Memory stacking feature using the package-on-package (POP) implementation (see Section 1.4, *Package-on-Package Concept*)

1.2 Environment

This section provides an overview of the OMAP environment. The device is associated with a power integrated circuit (IC). TI provides a global solution with the TWL50xx device.

Figure 1-1 is an overview of a nonexhaustive environment for the OMAP36xx device.

Figure 1-1. OMAP36xx High-Tier Environment

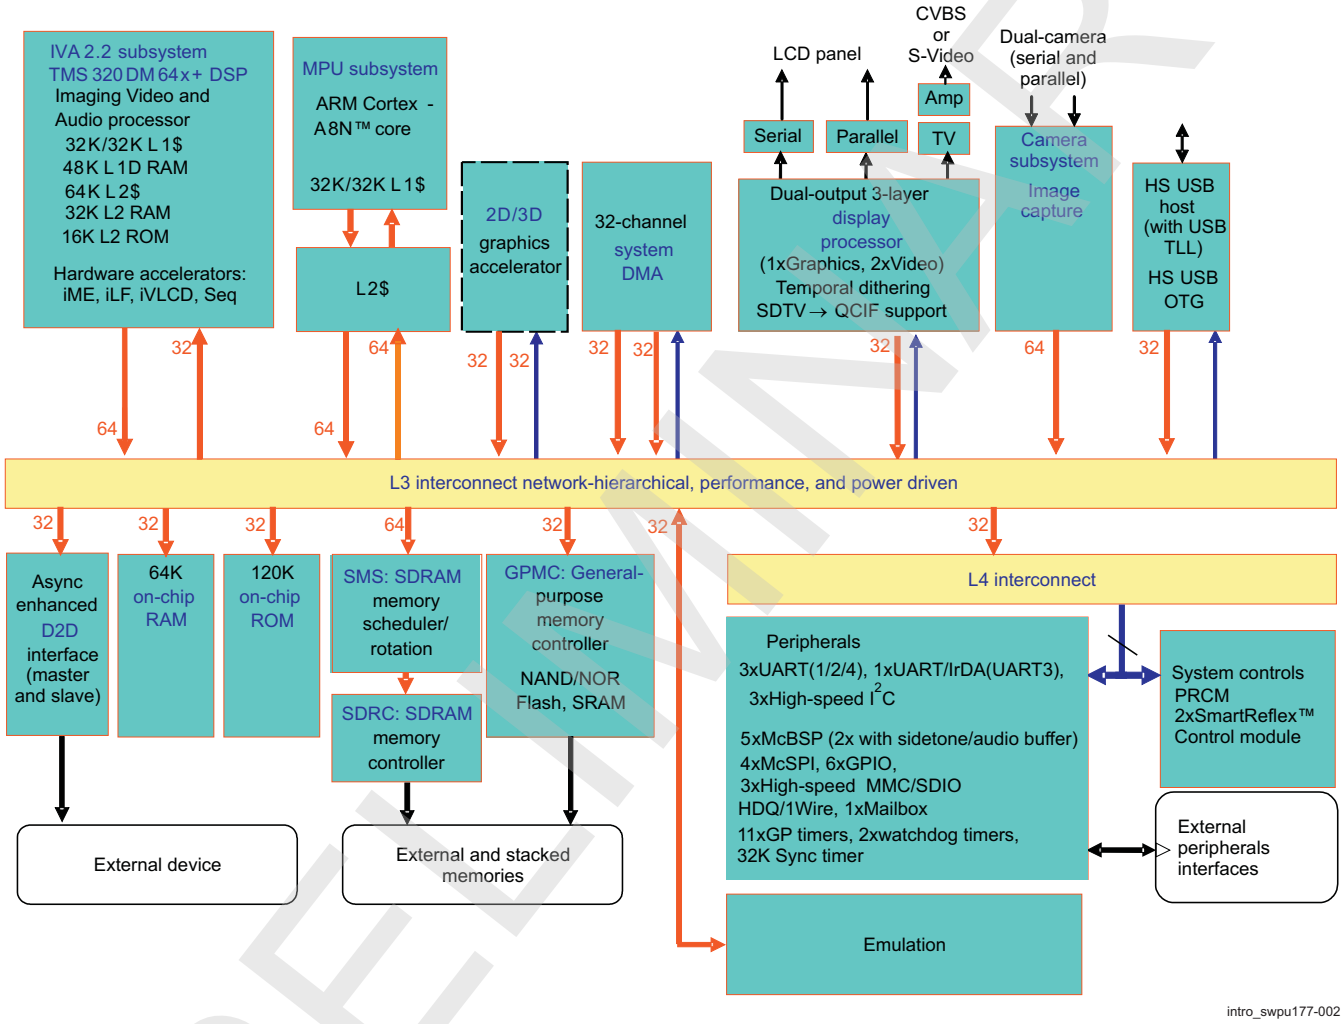


1.3 Description

The device is offered in the 515-ball, 12 x 12 mm, POP 0.5-mm (top) and 0.4-mm (bottom) ball pitch package. Some balls are available at the top of the device. (For more information, see Section 1.4, *Package-on-Package Concept*.)

Figure 1-2 is the OMAP36xx block diagram.

Figure 1-2. OMAP36xx Block Diagram



1.3.1 MPU Subsystem

The MPU subsystem integrates the following modules:

- ARM® subchip:
  - ARM Cortex-A8 core
  - ARM Version 7 ISA™: Standard ARM instruction set plus Thumb®-2, Jazelle® RCT Java accelerator, and media extensions
  - Neon™ SIMD coprocessor (VFP lite plus media streaming instructions)
  - Cache memories:
    - Level 1 (L1): 32-KB instruction and 32-KB data–4-way set associative cache, 64 bytes/line
    - Level 2 (L2): Up to 256KB.
- Interrupt controller (MPU INTC) of 96 synchronous interrupt lines
- Asynchronous interface with core logic

- Debug, trace, and emulation features: ICECrusher™, ETM™, and ETB™ modules

1.3.2 IVA2.2 Subsystem

The device includes a high-performance IVA2.2 accelerator based on the TI TMS320DMC64x+™ VLIW DSP core.

The IVA2.2 subsystem includes the following main features:

- 32-bit fixed-point media processor
- Very long instruction word (VLIW) architecture based on the programmable enhanced version of the C64x™ DSP core
- Eight instructions/cycle, eight execution units:
  - Optimized instruction set for video and imaging processing
  - Eight 8 x 8 or 16 x 16 multiply accumulate (MAC) per cycle
  - Eight slave asynchronous die (SAD) per cycle
  - Eight interpolations (a + b + 1)>>1 per cycle
  - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megacell:
  - Dynamically mixed 32-bit and 16-bit instruction sets
  - Software pipelined loop (SPLOOP) instruction buffer
  - Separate power domain
  - Supported multiple power-down states
- Two-level memory subsystem hierarchy:
  - L1P (program)
    - 32-KB direct-mapped cache–32-byte cache line, configurable as cache or memory mapped. The possible values are:
      - 0-KB cache/32-KB memory
      - 4-KB cache/28-KB memory
      - 8-KB cache/24-KB memory
      - 16-KB cache/16-KB memory
      - 32-KB cache/0-KB memory
  - L1D (data)
    - 32-KB 2-way set associative cache–4-byte cache line, configurable as cache or memory mapped. The possible values are:
      - 0-KB cache/32-KB memory
      - 4-KB cache/28-KB memory
      - 8-KB cache/24-KB memory
      - 16-KB cache/16-KB memory
      - 32-KB cache/0-KB memory
    - 48-KB memory-mapped static random access memory (SRAM)
  - L2 (program and data)
    - 64-KB 4-way set associative cache–128-byte cache line, configurable as cache or memory mapped. The possible values are:
      - 0-KB cache/64-KB memory
      - 32-KB cache/32-KB memory
      - 64-KB cache/0-KB memory
    - 32-KB memory-mapped SRAM
    - 16-KB ROM
- Video hardware accelerators:
  - Improved motion estimation (iME) dedicated hardware
  - Improved loop filtering (iLF) dedicated hardware
  - Improved variable length coder/decoder (iVLCD) with quantizing capabilities dedicated hardware

  - Video dedicated sequencer
  - Video local interconnect
  - Local L2 memory interface/arbiter
- Private direct memory access (DMA) controller:
  - 128 logical channels
  - 1D/2D addressing
  - Chaining capability
  - Fully pipelined, two 64-bit read ports, two 64-bit write ports
  - Single access 32-byte or 64-byte incrementing bursts
- L1 INTC
- Local IVA2.2 digital phase-locked loop (DPLL) supplying the IVA2.2 subsystem clocking
- 32-entry memory management unit (MMU) for seamless integration in high-level OS environment
- IVA2.2 system interfaces:
  - 64-bit L3 port shared for external memory accesses:
    - Multithreaded link shared by DSP core and DMA accesses
    - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3 interconnect
    - Incrementing burst support
    - Critical line first to reduce line fetch latency to the processor
  - Host port interface (HPI) for MMU programming and access to the IVA2.2 internal memories. Can be synchronous or asynchronous.
  - System interfaces: Clocking, power management
- C-friendly environment (state-of-the-art C compiler for VLIW architecture)
- Supports TI low-overhead DSP/BIOS™ operating system

1.3.3 On-Chip Memory

On-chip memory configuration offers memory resources for program and data storage:

- 120-KB ROM
- 64-KB single-access SRAM

1.3.4 External Memory Interfaces

The device includes two external memory interfaces supporting the stacking of a multichip memory package using the generic POP interface:

- General-purpose memory controller (GPMC):
  - NOR flash, NAND flash (with ECC Hamming code calculation), SRAM and pseudo-SRAM asynchronous and synchronous protocols
  - Flexible asynchronous protocol control for external ASIC or peripheral interfacing
  - 16-bit data, up to 8 chip-selects (CSs)
  - 1-GB total address space
  - Address bus up to 128-MB external memories
  - Address bus up to the 256-MB POP package
- SDRAM controller (SDRC):
  - Mobile single data rate (M-SDR) SDRAM and low-power double data rate (LPDDR) SDRAM
  - 16-bit or 32-bit data, two chip-selects, configurations for a maximum of 2GB supported on each chip-select
  - Work in conjunction with the SDRAM memory scheduler (SMS) companion module

1.3.5 DMA Controllers

The device embeds one generic DMA controller, the system DMA (sDMA) controller used for memory-to-memory, memory-to-peripheral, and peripheral-to-memory transfers:

- One read port, one write port
- 32 prioritizable logical channels
- 96 hardware requests
- 256 x 32-bit first in first out (FIFO) dynamically allocatable between active channels

The device also embeds three dedicated DMA controllers: enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem; display DMA; and universal serial bus (USB) high-speed (HS) DMA. It supports linked lists.

1.3.6 Multimedia

The device uses the following multimedia accelerators for display and gaming effects as well as high-end imaging and video applications.

NOTE: The SGX subsystem is an instantiation by Texas Instruments of the POWERVR® SGX530 core from Imagination Technologies Ltd.

- 2D and 3D graphics accelerator (POWERVR® SGX530):
  - 2D and 3D graphics and video codecs supported on common hardware
  - Tile-based architecture
  - USSE™ multithreaded engine incorporating pixel and vertex shader functionality reducing die area
  - Advanced shader feature set in excess of Microsoft VS3.0, PS3.0, and OpenGL™2.0
  - Industry standard API support Direct3D™ mobile, OpenGL™ ES 1.1 and 2.0, OpenVG™ 1.0.1, OpenMax
  - Fine-grained task switching, load balancing, and power management
  - Programmable high-quality image anti-aliasing
  - Advanced geometry DMA driven operation for minimum CPU interaction
  - Fully virtualized memory addressing for OS operation in a unified memory architecture
  - Advanced and standard 2D operations (for example, vector graphics, block level transfers, raster operations, etc.)
  - 32K stride support
- Camera ISP2P subsystem:
  - Supports most of the raw image sensors available in the market
  - Supports up to 128 bytes burst
  - Is backward-compatible with ISP2
  - Camera parallel interface (CPI), which is used to transfer data to the image signal processors. It is configurable to work as 10- or 12-bit interface.
  - Three serial interfaces: one, which is compatible with the CCP2/MIPI® CSI1 specification (CCP2B), and two, which are compatible with the MIPI CSI2 specification (CSI2A and CSI2C). There are serveral possible configurations between CPI and the serial interfaces via configuring the two PHY's.
  - Image signal processors (ISP2P) for hardware video processing:
    - Video processing front end (VBFE):
      - Optical clamping
      - Optical black clamp
      - Black-level compensation
      - Look-up table (LUT)-based faulty pixel correction
      - 2D lens-shading compensation
      - Data formatter
      - Output formatter

    - Video processing back end (VBBE):
      - Preview module
      - Resizer module
  - Circular buffer virtual rotated frame buffer (VRFB) context grouping feature added to speed up performance
  - Embedded DMA controller in CSI2 receiver
- Display subsystem
  - Display controller with embedded VDMA to increase performance
  - Color and monochrome displays up to 2048 x 2048 x 24-bpp resolution
  - 256 x 24-bit entries palette in red, green, blue (RGB)
  - Picture-in-picture (overlay), color-space conversion, rotation, color-phase rotation, and resizing support
  - Remote frame buffer interface
  - MIPI® Display serial interface (DSI) complex I/O module
  - Liquid-crystal display (LCD) pixel interfaces (MIPI DPI 1.0) and LCD bus interfaces (MIPI DBI 2.0) supported
  - NTSC/PAL video encoder outputs with integrated digital-to-analog converters (DACs) output are supported on CVBS and S-video TV analog output signals
  - Support of HDMI with 720 p throughput through the external bridge
  - Embedded DMA controller

1.3.7 Comprehensive Power Management

- Clock and reset generation and distribution
- Wake-up event management
- SmartReflex technology
- Dynamic voltage and frequency scaling
- Dynamic power switching
- Static leakage management
- Adaptive body bias
- Retention until access memories

1.3.8 Peripherals

The device supports a comprehensive set of peripherals to provide flexible and high-speed interfacing and on-chip programming resources:

- Universal asynchronous receiver/transmitter (UART) 1/2/4
  Three general serial communication interfaces
- UART 3:
  UART + IrDA SIR up to FIR + TV remote control interface (CIR)
- Multichannel buffered serial port 1 (McBSP1), McBSP2, McBSP3, McBSP4, and McBSP5
  Three general-purpose (McBSP1, McBSP4, and McBSP5) and two audio-loopback capable (McBSP2 and McBSP3 associated with two sidetone modules) multichannel-buffered serial interfaces
- I2C1, I2C2, and I2C3:
  Three master/slave inter-integrated circuit (I^2C) high-speed standard interfaces
- HDQ™/1-Wire®:
  Benchmark HDQ and Dallas Semiconductor 1-Wire protocol interfaces
- Multichannel serial port interface 1 (McSPI1), McSPI2, McSPI3, and McSPI4:
  Four McSPI controllers
- High-speed multiport USB host:
  High-speed USB host that is used for (local) interprocessor communication (that is, from OMAP to modems) using TLL mode
- High-speed USB On-The-Go (OTG):

High-speed controller that offers high-speed data transactions (up to 480 Mbps) on a USB port (ULPI 12 bits) with embedded DMA controller

- High-speed MMC/SD/SDIO 1/2/3:
  Three interface controllers for HS MMC/SD/SDIO standards
- General-purpose (GP) timers:
  Eleven GP timers
- Watchdog timers (WDTs):
  Two watchdog timers
- 32-kHz synchronization timer:
  32-kHz clock timer
- General-purpose input/output (GPIO):
  Six 32-bit, GPIO controllers
- Mailbox:
  MPU/IVA2.2 interprocessor communications (six in stacked mode, two in stand-alone mode)
  ICR (only in stacked mode)
- Control module:
  I/O multiplexing and chip-configuration control

1.4 POP Concept

The OMAP die uses flip-chip technology. The OMAP36xx POP device supports memory stacking using a POP implementation.

The POP device provides a generic POP memory interface to support multiple stacked package configurations, including the flash multichip package, depending on customer needs.

The stacked memory package is connected directly to the two memory interfaces (GPMC and SDRC) of the POP device through the POP interface present at the top. (For more information about the interconnect between the stacked memory package and the POP device, see Chapter 10, *Memory Subsystem*).

Figure 1-3 shows the concept of the POP solution, and Figure 1-4 shows stacked memory package on the POP device.

Figure 1-3. POP Concept

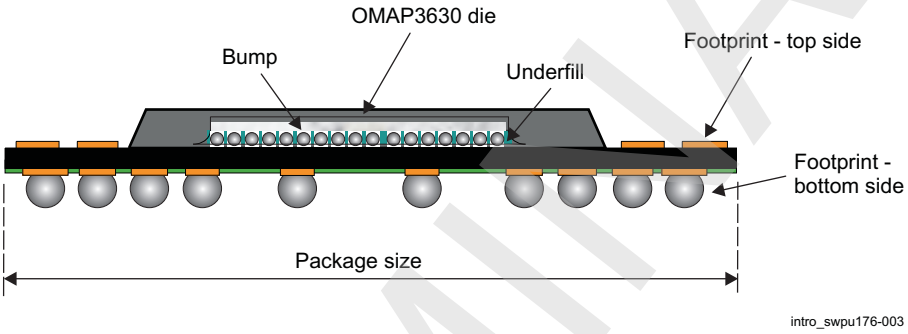


Figure 1-4. Stacked Memory Package on the POP Device

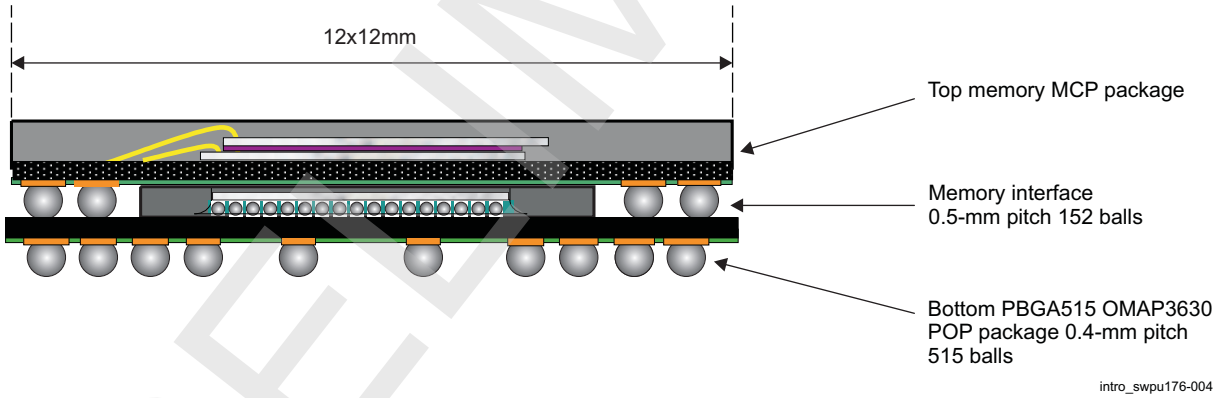


The memory interfaces must be configured correctly based on the memory package used with the POP device.

Table 1-1 summarizes the supported configurations with the generic POP interface.

NOTE: For other types of memory, the traditional GPMC interface can be used through the board.

Table 1-1. Summary of Memories Supported by the POP Interface

Generic POP Interface Features Set	SDRC Interface	GPMC Interface
Type of memory supported	DDR	NOR flash asynchronous and synchronous burst flash NAND flash "CE don't care" One NAND on CS0 and CS1 NOR flash address/data nonmultiplexed is not supported.
Number of chip-selects	2	2
Maximum density per chip-select	2GB	2GB
Maximum size per interface	4GB	4GB
Interface width	X 32 bits	X 16 bits
I/O voltage	1.8 V LVCMOS	1.8-V LVCMOS

For more information on the memory interface configuration, see Chapter 10, *Memory Subsystem*.

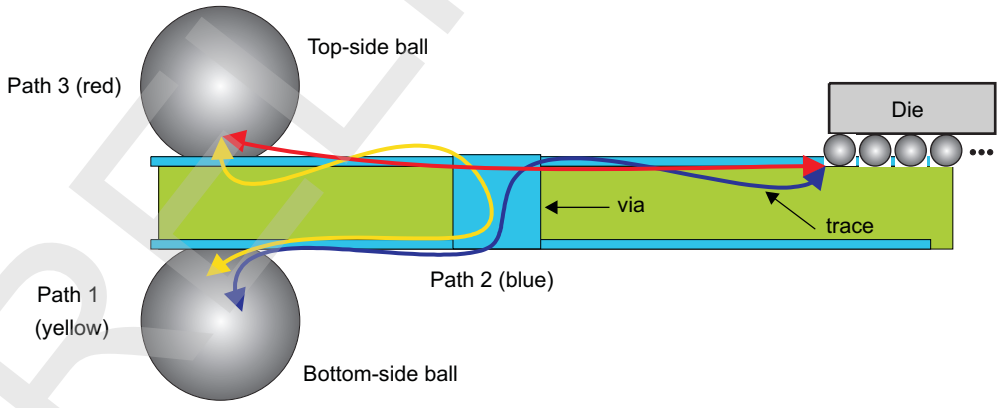
The POP device includes feedthroughs in addition to the GPMC and SDRC interfaces positioned at the top of the package. There are several feedthroughs from the bottom ball-grid array (BGA) to the top (or POP) interface to support different memory combinations.

The feedthroughs provide power to a top memory device or provide specific memory signals from the bottom BGA to the POP interface.

NOTE: It is possible to monitor the DDR SDRAM temperature if the memory multichip package allows the temperature sensing option. A feedthrough is used to lower the temperature-sensing dedicated signal to make a connection with a GPIO. For more information about DDR SDRAM temperature-sensing management, see Chapter 10, *Memory Subsystem*, and Chapter 25, *General-Purpose Interface*.

Figure 1-5 shows the implementation of feedthroughs on the POP and the different paths between the bottom and top of the package.

Figure 1-5. Stacked Memory Package on the POP Device



(1) Path 1: Feedthrough only; Path 2: All but feedthrough; Path 3: POP interface (SDRC plus subset GPMC)

(2) Any signal available on the POP interface to a top-side ball is also available to a bottom-side ball.

1.5 OMAP36xx Family

The OMAP36xx family is composed of the following devices:

- OMAP3630
- OMAP3621
- OMAP3611

NOTE: For more information about OMAP3621 and OMAP3611, see Appendix A, *OMAP36x1 Multimedia Devices*.

Table 1-2. Device Features

Feature	OMAP3630	OMAP3621	OMAP3611

(1) Full-speed clock

1.6 Device Identification

The identification registers include the CONTROL.CONTROL_IDCODE, CONTROL_PRODUCTION_ID, and CONTROL.CONTROL_DIE_ID data registers. These registers are read-only accessed ports that are programmed into eFuses FARM FROM.

The device type and some options can be read in the CONTROL.CONTROL_PRODUCTION_ID register.

Memory Mapping

This chapter describes memory mapping in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic **Page**

2.1 Introduction

The microprocessor unit (MPU) has a 32-bit address port, allowing it to handle a 4-GB space divided into several regions, depending on the target type.

The memory map is composed of a memory space (general-purpose memory controller [GPMC], synchronous dynamic random-access memory [SDRAM] controller [SDRC], etc.), register space (level 3 [L3] and level 4 [L4] interconnects), and dedicated spaces (image and video accelerator [IVA2.2] subsystem, graphics accelerator (SGX), etc.), all of which are shared among the initiators (for example, the MPU subsystem or the IVA2.2 subsystem).

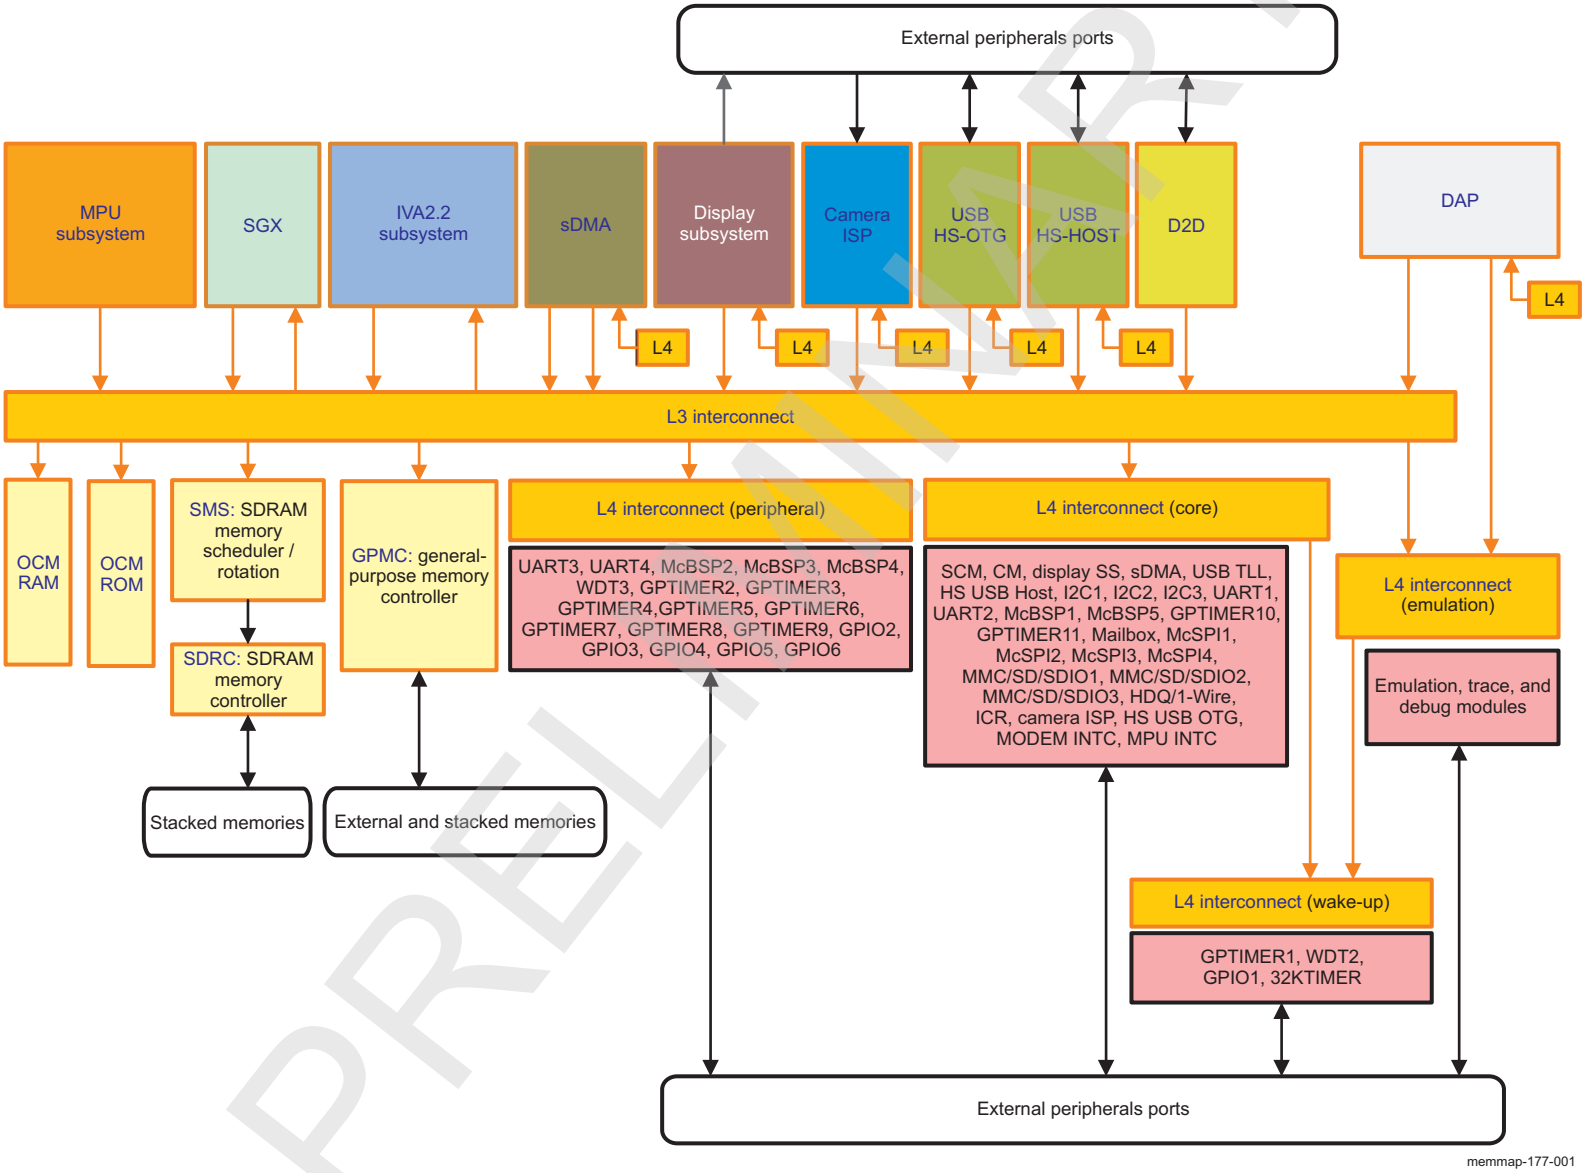
The GPMC and SDRC are dedicated to memory connection. The GPMC is used for NOR/NAND flash and SRAM memories. The SDRC is used for SDRAM memories, such as regular SDR-SDRAM (single data rate), regular JEDEC DDR1 memory (double data rate), low-power SDR-SDRAM, and mobile DDR-SDRAM. For more information, see Chapter 10, *Memory Subsystem*.

The L3 interconnect allows the sharing of resources, such as peripherals and external or on-chip memories, among all the initiators of the platform. The L4 interconnects control access to the peripherals.

Transfers between initiators and targets across the platform are physically conditioned by the chip interconnect and can be logically conditioned by firewalls. For more information about the intercommunication (L3 and L4 interconnects) and protection mechanisms implemented in the device, see Chapter 9, *Interconnect*.

Figure 2-1 shows the interconnect of the device and the main modules and subsystems in the platform.

Figure 2-1. Interconnect Overview



2.2 Global Memory Space Mapping

This section provides a global view of the memory mapping and describes the boot, GPMC, SDRC, and virtual rotated frame buffer (VRFB) memory spaces.

The system memory mapping is flexible, with two levels of granularity for target address space allocation:

- Level 1 (L1): Four quarters are labeled Q0, Q1, Q2, and Q3. Each quarter corresponds to a 1-GB address space (total address space is 4GB).
- Level 2 (L2): Each quarter is divided into eight blocks of 128MB, with target spaces mapped in the blocks.

This organization allows all target spaces to be decoded based on the five most-significant bits (MSBs) of the 32-bit address ([31:27]).

- **Boot space**

  The system has a 1-MB boot space in the on-chip boot ROM or on the GPMC memory space.

  When booting from the on-chip ROM with the appropriate external sys_boot5 pin configuration, the 1-MB memory space is redirected to the on-chip boot ROM memory address space [0x4000 0000 – 0x400F FFFF].

  When booting from the GPMC with the appropriate external sys_boot5 pin configuration, the memory space is part of the GPMC memory space.

  For more information about sys_boot5 pin configuration, see Chapter 10, *Memory Subsystem*, and Chapter 26, *Initialization*.
- **GPMC space**

  Eight independent GPMC chip-selects (gpmc_ncs0 to gpmc_ncs7) are available in the first quarter (Q0) of the addressing space to access NOR/NAND flash and SRAM memories. The chip-selects have a programmable start address and programmable size (16, 32, 64, or 128MB) in a total memory space of 1GB.
- **SDRC space**

  Two SDRC chip-selects (sdrc_ncs0 and sdrc_ncs1) are available on the third quarter (Q2) of the addressing space to access SDRAM memories. The chip-selects have a programmable size (64, 128, or 256MB) in a total memory space of 1GB (256MB per chip-select).

  The base address of the chip-select 0 (sdrc_ncs0) memory space is always 0x8000 0000. The base address of the chip-select 1 (sdrc_ncs1) memory space is programmable. The default value after reset is 0xA000 0000.
- **VRFB space**

  The SDRC-SMS virtual memory space is a different memory space used to access a subset of the SDRC memory space through the rotation engine (ROT). The virtual address space size is 768MB split into two parts: The first 256-MB part is in the second quarter (Q1) of the memory; the second 512-MB part is in the fourth quarter (Q3) of the memory.

For more information about boot, GPMC, SDRC, and VRFB, see Chapter 10, *Memory Subsystem*.

This section describes all modules and features in the high-tier device. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Table 2-1 describes the global memory space mapping.

Table 2-1. Global Memory Space Mapping

Quarter	Device Name	Start Address (Hex)	End Address (Hex)	Size	Description

Q3 (1GB)	**Reserved**			**512MB**	**Reserved**
	Reserved	0xC000 0000	0xDFFF FFFF	512MB	Reserved for future use
	SDRC/SMS			**512MB**	**SDRC/SMS**
	SDRC/SMS virtual Address space 1	0xE000 0000	0xFFFF FFFF	512MB	SDRC-SMS virtual address space 1

(4) Chip-select 0 and chip-select 1 spaces are configurable in the 1-GB SDRC/SMS space.

2.3 L3 and L4 Memory Space Mapping

The memory space system is hierarchical: L1, L2, L3, and L4.

L1 and L2 are memories in the MPU and IVA2.2 subsystems.

The chip-level interconnect, which consists of one L3 and four L4s, enables communication among all modules and subsystems.

L3 handles many types of data transfers, including data exchange with system on-chip/external memories.

The four L4s handle transfers with peripherals, but are in four distinct power domains: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects, which are in the CORE, WKUP, PER, and EMU power domains, respectively.

For more information about the interconnect, see Chapter 9, *Interconnect*.

The following sections describe the register mapping of the L3 and L4 interconnects. Software configures these registers.

2.3.1 L3 Memory Space Mapping

The L3 interconnect control registers are mapped in a 16-MB space and allow the configuration of the L3 interconnect parameters.

The L3 default settings are fully functional and enable all possible functional data paths. However, the interconnect parameters can be changed to accommodate requirements.

Accesses to the L3 interconnect can be configured on a per-module basis using the internal L3 registers, which are grouped into five register block types:

- IA: Initiator agent configuration registers
- TA: Target agent configuration registers
- RT: Register target (global) configuration registers
- PM: Protection mechanism (firewalls) configuration registers
- SI: Global sideband signal configuration registers

For more information, see Chapter 9, *Interconnect*.

This section describes all modules and features in the high-tier device. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Table 2-2 describes the mapping of the L3 interconnect control registers.

Table 2-2. L3 Control Register Mapping

2.3.2 L4 Memory Space Mapping

The device contains four L4 interconnects: L4-Core, L4-Wakeup, L4-Per, and L4-Emu.

As with the L3 interconnect, the L4 interconnects can be configured to tune the access depending on the characteristics of each module.

For more information about the L4 interconnect, see Chapter 9, *Interconnect*.

2.3.2.1 L4-Core Memory Space Mapping

The L4-Core interconnect is a 16-MB space composed of the L4-Core interconnect configuration registers and the module registers.

Table 2-3 describes the mapping of the registers for the L4-Core interconnect.

NOTE: All memory spaces described as modules provide direct access to module registers outside the L4-Core interconnect. All other accesses are internal to the L4-Core interconnect.

This section describes all modules and features in the high-tier device. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Table 2-3. L4-Core Memory Space Mapping [(1)]

Device Name	Start Address (Hex)	End Address (Hex)	Size	Description

2.3.2.2 L4-Wakeup Memory Space Mapping

The L4-Wakeup interconnect is a 256-KB space composed of the L4-Wakeup interconnect configuration registers and the module registers.

Table 2-4 describes the mapping of the registers for the L4-Wakeup interconnect.

NOTE: All memory spaces described as modules provide direct access to module registers outside the L4-Wakeup interconnect. All other accesses are internal to the L4-Wakeup interconnect.

Table 2-4. L4-Wakeup Memory Space Mapping

(1) These modules are accessed through the L4-Wakeup interconnect (for emulation only).
(2) The registers mapped in this range are shadow registers of the first 2-KB region A [0x5470 6000 – 0x5470 67FF]. Regions A and B share the same port.
(3) These modules are accessed through the L4-Wakeup interconnect (for emulation only).

2.3.3 Register Access Restrictions

This section describes all modules and features in the high-tier device. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Table 2-7 lists the supported data access widths per module.

Table 2-7. Register Access Restrictions

Module	Allowed Access (Bits)
MPU subsystem	8/16/32
IVA2.2 subsystem	32
SGX subsystem	32

2.4 IVA2.2 Subsystem Memory Space Mapping

This section describes the hardware accelerators of IVA2.2. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

The device includes the high-performance Texas Instruments IVA2.2. For more information, see Chapter 5, *IVA2.2 Subsystem*.

This section describes how internal memories and registers of the IVA2.2 are accessed through the L3 interconnect and by the internal initiators of the IVA2.2 (the digital signal processor [DSP] and the enhanced direct memory access [EDMA]).

Three views of the IVA2.2 subsystem memory space mapping are provided:

- L3 interconnect view: External view (subsystem memories and configuration registers) as seen by the MPU subsystem and most of the initiators of the platform through the L3 interconnect
- IVA2.2 DSP view: Internal view as seen by the DSP
- IVA2.2 EDMA view: Internal view as seen by the EDMA

NOTE: The IVA2.2 subsystem also contains a local interconnect with its own memory space mapping that can be accessed only by the DSP and the video accelerator and sequencer in the IVA2.2 subsystem. For more information about this video accelerator/sequencer local interconnect and its memory space mapping, see Chapter 5, *IVA2.2 Subsystem*.

2.4.1 IVA2.2 Subsystem Internal Memory and Cache Allocation

2.4.1.1 IVA2.2 Subsystem Memory Hierarchy

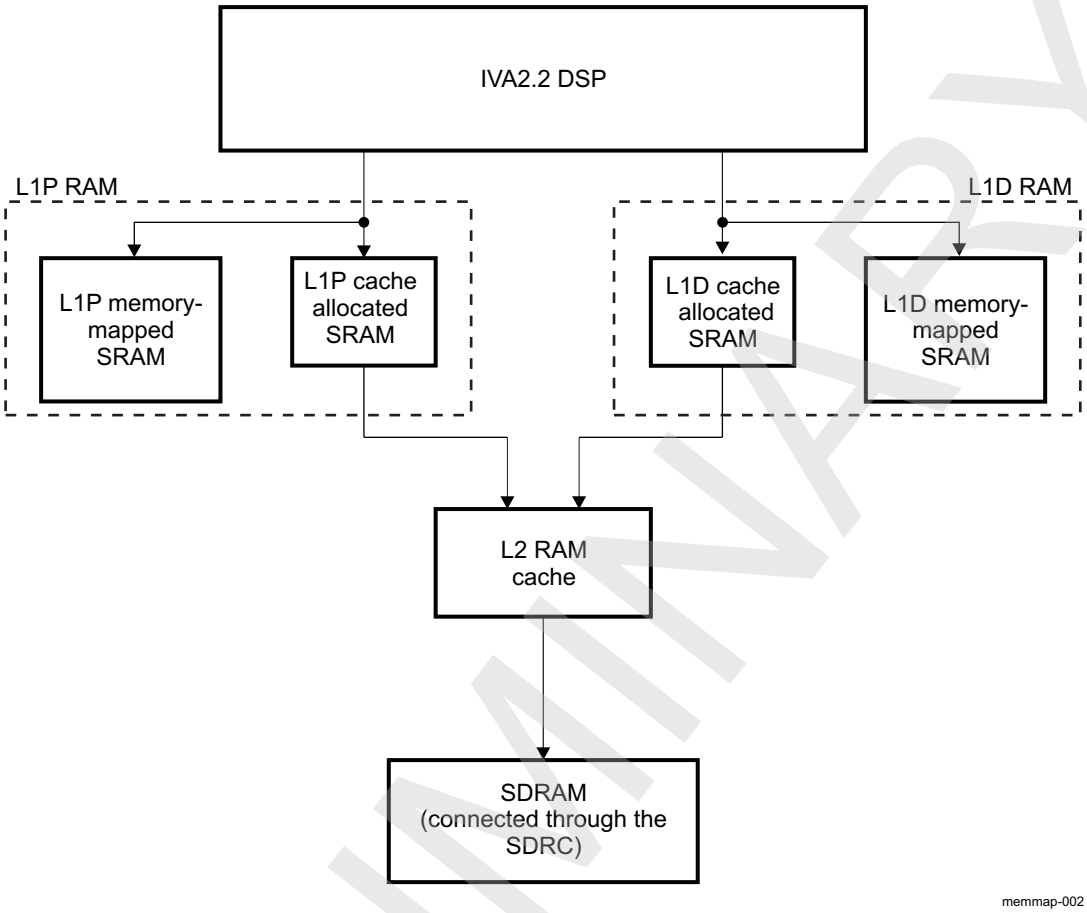
The IVA2.2 subsystem includes the following memory features:

- L1P (program)
  - 32-KB configurable: Memory-mapped (default after reset) or direct-mapped cache—32-byte cache line
- L1D (data)
  - 32-KB configurable: Memory-mapped (default after reset) or 2-way set associative cache—64-byte cache line
  - 48-KB memory-mapped
- L2 (program and data)
  - 64-KB configurable: Memory-mapped (default after reset) or 2-way set associative cache—128-byte cache line
  - 32-KB memory-mapped
  - 16-KB ROM

The local memories can be used as cache RAMs or memory-mapped RAMs, depending on the configuration of the different memory controllers in the IVA2.2 subsystem.

Figure 2-2 shows the memory hierarchy of the IVA2.2 subsystem.

Figure 2-2. IVA2.2 Subsystem Memory Hierarchy



2.4.1.2 IVA2.2 Cache Allocation

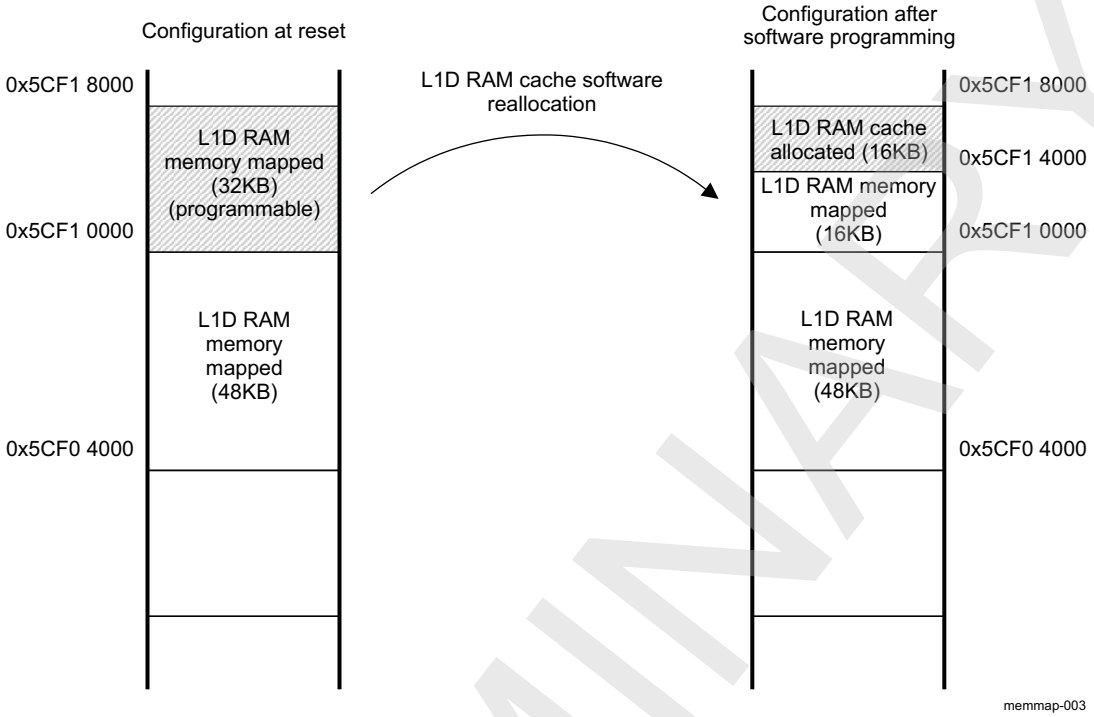
After reset, the L1P RAM is used as a 32-KB memory-mapped RAM. The L1P RAM can be programmed in the C64x+ ™ DSP program memory controller to allocate 0 (default), 4, 8, 16, or 32KB to cache. When 32KB are allocated to cache, there is no more memory-mapped L1P.

After reset, the L1D RAM is used as an 80-KB memory-mapped RAM. The L1D RAM can be programmed in the C64x+ DSP data memory controller to allocate 0 (default), 4, 8, 16, or 32KB to cache. When 32KB are allocated to cache, 48KB are still allocated to the memory-mapped L1D.

After reset, L2 is used as a 96-KB memory-mapped RAM. L2 can be programmed to allocate 0 (default), 32, or 64KB to cache. When 64KB are allocated to cache, 32KB are still allocated to memory-mapped L2.

Figure 2-3 is an example of the L1D RAM cache allocation, where 16KB are allocated to cache.

Figure 2-3. L1D RAM Cache Allocation Example (L3 Interconnect View)



2.4.2 DSP Access to L2 Memories

2.4.2.1 DSP Access to L2 ROM

The IVA2.2 subsystem contains 16KB of L2 ROM. The L2 ROM provides boot code.

When the L1P cache is configured to be inactive (default configuration), DSP program fetch accesses to the L2 ROM are performed directly, and thus suffer the L2 latency.

When the L1P cache is configured to be active, DSP program fetch accesses to L2 ROM are always serviced by the L1P cache controller, which partly hides the L2 latency.

2.4.2.2 DSP Access to L2 RAM

The IVA2.2 contains 96KB of L2 RAM. The L2 RAM can be configured to allocate up to 64KB to the L2 cache.

When the L1P and L1D caches are configured to be inactive (default configuration), DSP accesses to the L2 RAM are accomplished directly, and thus suffer the L2 latency.

When the L1P and L1D RAM are configured to be active, DSP program accesses to L2 RAM are always serviced by the L1P cache controller (if code fetch) or the L1D cache controller (if data access), which partly hides the L2 latency

2.4.3 DSP and EDMA Access to Memories and Peripherals

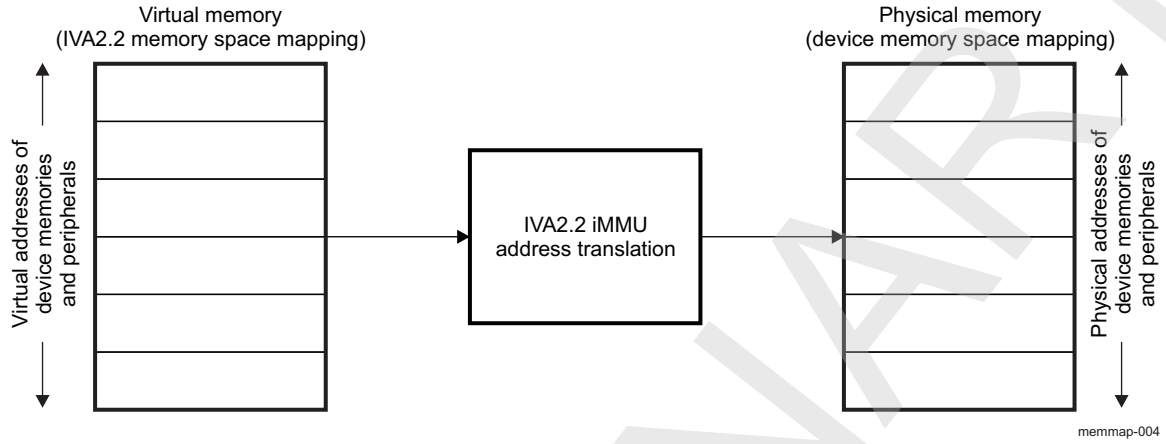
The IVA2.2 DSP and EDMA access the memories and peripherals using virtual addressing. This lets the DSP and EDMA access memories and peripherals in the same contiguous view, even when the memory is physically segmented. Table 2-9 and Table 2-10 give the address range where the DSP and the EDMA can access the memories and peripherals, respectively.

The IVA2.2 memory management unit (IVA2.2 iMMU) handles the virtual-to-physical address translation based on the software configuration (typically under control of the MPU subsystem).

Virtual addresses are issued by the initiator to the IVA2.2 iMMU. Using the translation look-aside buffer (TLB), the MMU translates the initiator virtual addresses into real physical addresses.

Figure 2-4 shows the relationship among physical addresses, virtual addresses, and the IVA2.2 iMMU.

Figure 2-4. IVA2.2 iMMU Address Translation



For more information about the MMU, see Chapter 15, *Memory Management Units*.

2.4.4 L3 Interconnect View of the IVA2.2 Subsystem Memory Space

Table 2-8 lists the IVA2.2 subsystem memory space mapping from the perspective of the MPU subsystem through the L3 interconnect.

Power, Reset, and Clock Management

This chapter describes power, reset, and clock management in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Topic **Page**

3.1 Introduction to Power Managements

This introduction contains the following information:

- Requirement and goal of power management in mobile devices
- State-of-the-art power-management techniques for maximizing battery life for mobile devices
- Essential architectural building blocks for power management
- Overview of the device power-management architecture

3.1.1 Goal of Power Management

Power management (efficient use of the available limited battery resources of a mobile device) is one of the most important design aspects of any mobile system. It imposes strong control over limited available power resources to ensure that they function for the longest possible time.

The device architecture ensures maximum performance for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements.

3.1.2 Power-Management Techniques

The following sections describe the state-of-the-art power-management techniques supported by the device.

NOTE: The values in Figure 3-1 through Figure 3-4, which show power-management techniques, are hypothetical only. They do not represent valid test results on the device.

3.1.2.1 Dynamic Voltage and Frequency Scaling

Dynamic voltage and frequency scaling (DVFS) reduces the device voltage and frequency by minimizing the idle time of the system. The DVFS technique uses dynamic selection of the optimal operating frequency and voltage to let a task be performed in the required amount of time. This reduces the active power consumption (power consumed while executing a task) of the device while still meeting task requirements.

Figure 3-1 compares energy consumption with and without DVFS.

Figure 3-1. Comparison of Energy Consumption With/Without DVFS

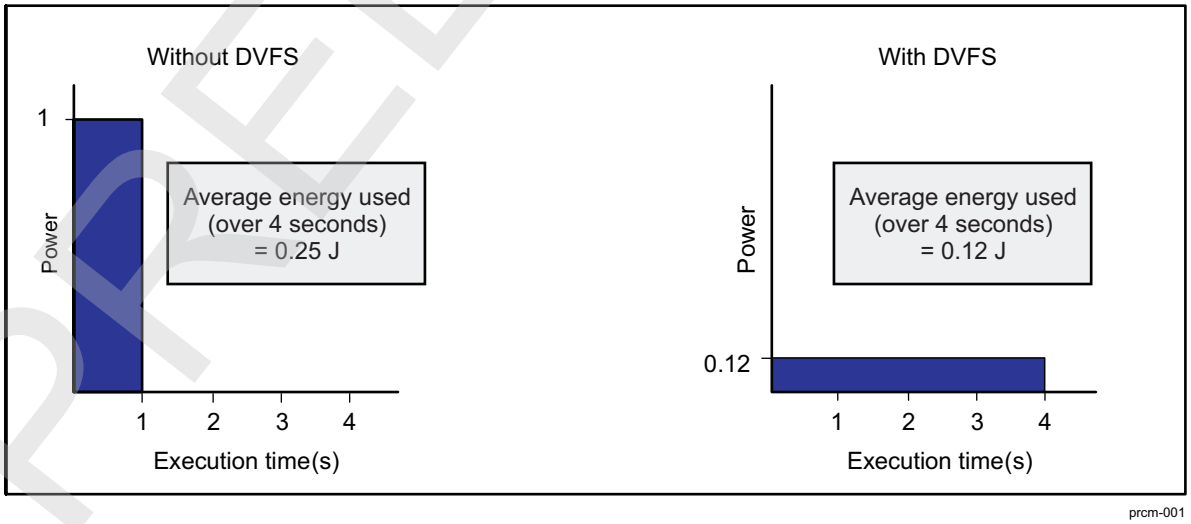

Figure 3-1 shows the DVFS technique by comparing a process executed at maximum frequency and operating voltage without applying DVFS to the same process executed at optimal frequency and voltage using DVFS, based on the task requirements. If a task that must terminate in 4 seconds is performed at

maximum operating frequency (left side of the figure), it terminates in 1 second, and the remaining 3 seconds are spent in idle mode. With DVFS (right side of the figure), the operating frequency is reduced to an optimal level; the task takes the full 4 seconds to complete, but power consumption is reduced. In addition, voltage can be further reduced to save power so dynamic and leakage power consumption are reduced.

DVFS requires control over the clock frequency and the operating voltage of the device elements. By intelligently switching the individual elements of the device to their optimal operating points, it is possible to minimize the power consumption of the device for a given task.

For practical reasons related to device making (flow, tools), DVFS can be used for only a few discrete steps, not over a continuum of voltage and frequency values. Each step, or operating performance point (OPP), is composed of a voltage (V) and frequency (F) pair. For an OPP, the frequency corresponds to the maximum frequency allowed at a voltage, or reciprocally, the voltage corresponds to the minimum voltage allowed for a frequency.

When applying DVFS, a processor or system always runs at the lowest OPP that meets the performance requirement at a given time. The user determines the optimal OPP for a given task and then switches to that OPP to save power.

3.1.2.2 SmartReflex? Adaptive Voltage Scaling (AVS)

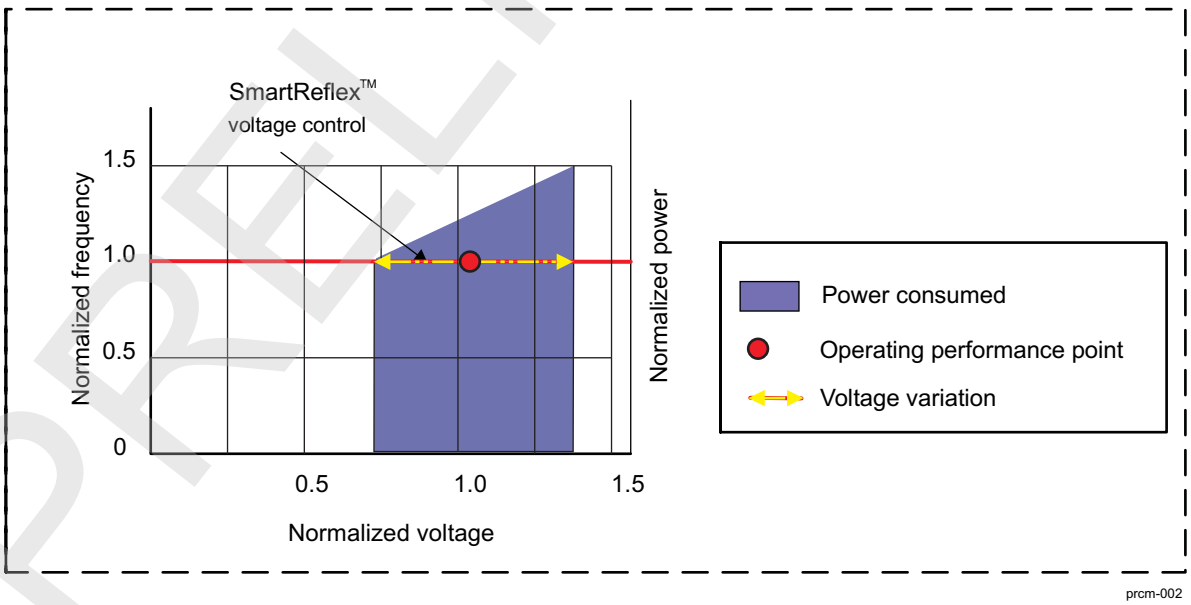
SmartReflex is a power-management technique for automatic control of the operating voltage of a module to reduce active power consumption.

With SmartReflex, power-supply voltage is adapted to silicon performance, statically (based on performance points predefined in the manufacturing process of a given device) or dynamically (based on the temperature-induced real-time performance of the device). A comparison of these predefined performance points to the real-time on-chip measured performance determines whether to raise or lower the power-supply voltage.

SmartReflex achieves the optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variations.

Figure 3-2 shows an example of SmartReflex power management.

Figure 3-2. SmartReflex Example



In Figure 3-2, the self-adjusting voltage scaling with SmartReflex ensures the frequency performance of the current OPP. For a given device operating frequency, the device voltage is automatically adapted to maintain performance of the device. This ensures optimal power consumption for a given OPP.

With SmartReflex, the frequency steps are identified and the voltage is adapted according to the silicon performance of the device. In this case, instead of a voltage step for each frequency step, there is a corresponding range of voltages. The range depends on the fabrication process of the device and its real-time operating state (temperature) at a given frequency.

3.1.2.3 Dynamic Power Switching

Like DVFS, dynamic power switching (DPS) is a power-management technique that reduces active power consumption of a device. However, whereas DVFS reduces dynamic and leakage power consumption, DPS reduces only leakage power consumption, at the expense of a slight overhead in dynamic power consumption.

With DPS, the system switches dynamically between high- and low-consumption system power modes during system active time. When DPS is applied, a processor or system runs at the highest OPP (maximum frequency and voltage) to complete its tasks quickly, followed by an automatic switch to a low-power mode for minimum power consumption. DPS is useful when a real-time application is waiting for an event. The system can switch to a low-power system mode if the wake-up latency conditions allow it.

This technique consists of maximizing the idle period of the system to reduce its power consumption.

Figure 3-3 compares energy consumption with and without DPS.

Figure 3-3. Comparison of Energy Consumed With/Without DPS

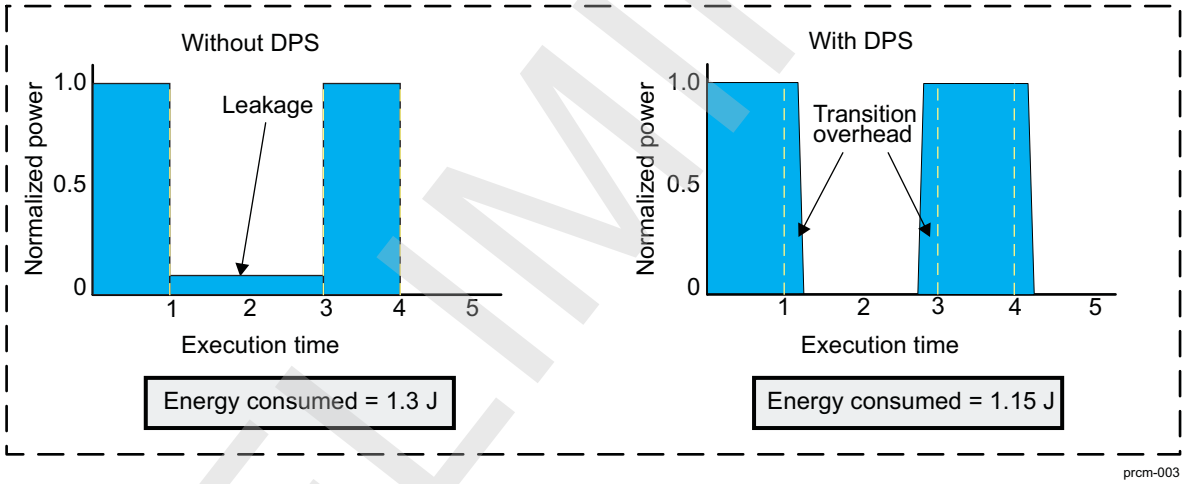


Figure 3-3 compares the power consumption behavior for the same device operation without DPS (left side of the figure) and with DPS (right side of the figure). When operating without DPS, the device has a constant leakage current in idle mode. By using DPS, the system reduces the leakage current to zero. However, the transitions between system power modes can require storing the information before entering a low-power inactive state and restoring the information after a wake-up event (see Figure 3-3). This results in additional dynamic power consumption, referred to as the transition overhead, (see Figure 3-3). Transition overhead must be considered for a DPS operation.

For efficient deployment of DPS techniques, it is necessary to dynamically predict the performance requirement of the applications running on the processor. The DPS controller must account for the overhead of wake-up latencies related to domain switching and ensure that they do not significantly affect the performance of the device. Even with transition overhead, however, the user can identify an optimal idle-time limit after which the DPS is useful for dynamic power-saving.

3.1.2.4 Standby Leakage Management

Standby leakage management (SLM) is a power-management technique that reduces standby power consumption by reducing power leakage.

With SLM, the device switches to low-power system modes automatically or in response to user requests during system standby (in situations when no application is started and system activity is negligible or limited).

When applying SLM, the system remains in the lowest static power mode compatible with the system response time requirement.

This technique trades static power consumption for wake-up latency.

3.1.2.5 DPS Versus SLM

DPS and SLM are similar concepts: they consist of switching the system between high- and low-power consumption modes. However, their operating timescales differ, principally in the latency allowed for mode transitions.

DPS is generally used in an applicative context (tasks are started). Therefore, mode transitions are related to system performance requirements or the processor load. DPS transition latencies must be small (typically between 10 μs and 100 μs) compared to the time constraints or deadlines of the application so that they do not degrade application performance. DPS requires performance prediction to ensure that transition latencies do not deteriorate device performance to the point that real-time application deadlines are missed or the user experience degrades too much for an interactive application.

SLM is not used in an applicative context (no task started). Mode transitions are more related to system responsiveness, and the transition latencies must be small compared to user sensitivity so that they do not degrade the user experience. For SLM, transition latencies are typically 1 ms to 10 ms or more.

DPS and SLM also differ in the type of wake-up event used to exit low-power idle mode. For DPS, wake-up events are application-related (timer, DMA request, peripheral interrupt, etc.); for SLM, wake-up events are user-related (touch screen, key pressed, peripheral connections, etc.).

3.1.2.6 Adaptive Body Bias (ABB)

The device implements the following transistor body bias technique:

- Forward Body-Bias (FBB) for operating clock frequency boost for operation at higher operating performance points (OPPs).

ABB is based on the process corner and the current OPP. This is configured in the efuse at the device characterization and is not continuously updated. A dedicated LDO, i.e. VBBLDO is used to produce the voltage bias.

3.1.2.7 Combining Power-Management Techniques

The DVFS, DPS, SLM, and SmartReflex power-management techniques have different features and are most effective when used under specific device operating conditions. Hence, the best active power saving is obtained by combining the techniques. For a given operating state, one or more of the power-saving techniques can be applied to ensure optimal operation with maximum power saving.

SmartReflex can be used at boot time to adapt the voltage to device process characteristics (strong/weak) and then used continuously to compensate for temperature variations. It can also ensure maximum available application performance of the device at a given OPP.

When medium application performance is required, or when application performance requirements vary, DVFS can be applied. The voltage and frequency can be scaled to match the closest OPP that meets the performance requirement.

When application performance requirements fall between two OPPs, or when required application performance is below the lowest performance OPP, DPS can be applied to switch to low-power mode.

When combining DVFS and DPS, the operating frequency must not be scaled to match the performance requirement without scaling the voltage. Lower operating frequency increases task completion time and reduces idle time. This prevents DPS or reduces its efficiency (DPS becomes more effective as idle time increases). Unless DPS cannot be applied for other reasons, for a given operating point of DVFS, the operating frequency must always be set to the maximum allowed at a given voltage. This ensures optimal process completion time and application of DPS.

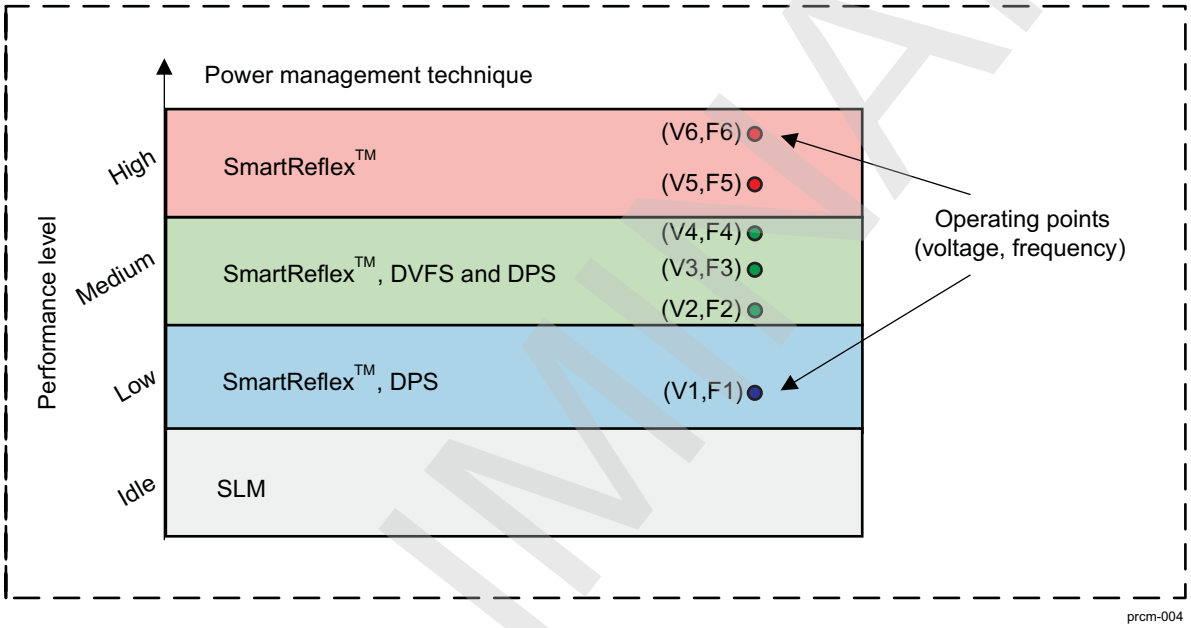
If DPS cannot be applied in a given context, scaling the frequency while keeping the voltage constant does not save energy. It does, however, reduce peak power consumption. This can have a positive effect on temperature dissipation and battery life.

In situations where no applications are running and performance requirement drops to zero, SLM must be used.

Figure 3-4 compares combinations of the power-management techniques.

NOTE: The OPPs shown in Figure 3-4 are for explanation only. They do not correspond to validated OPPs of the device.

Figure 3-4. Performance Level and Applied Power-Management Techniques



3.1.3 Architectural Blocks for Power Management

The device supports the power-management techniques through three architectural blocks: the power, clock, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (clock, voltage, or power switching).

3.1.3.1 Clock Domain

A clock domain is a group of modules fed by the same gated clock signal (see Figure 3-5). By gating the clock to each domain, it is possible to cut a clock to a group of inactive modules to lower their active power consumption. Thus, a clock domain allows control of dynamic power consumption by the device.

Figure 3-5. Generic Clock Domain

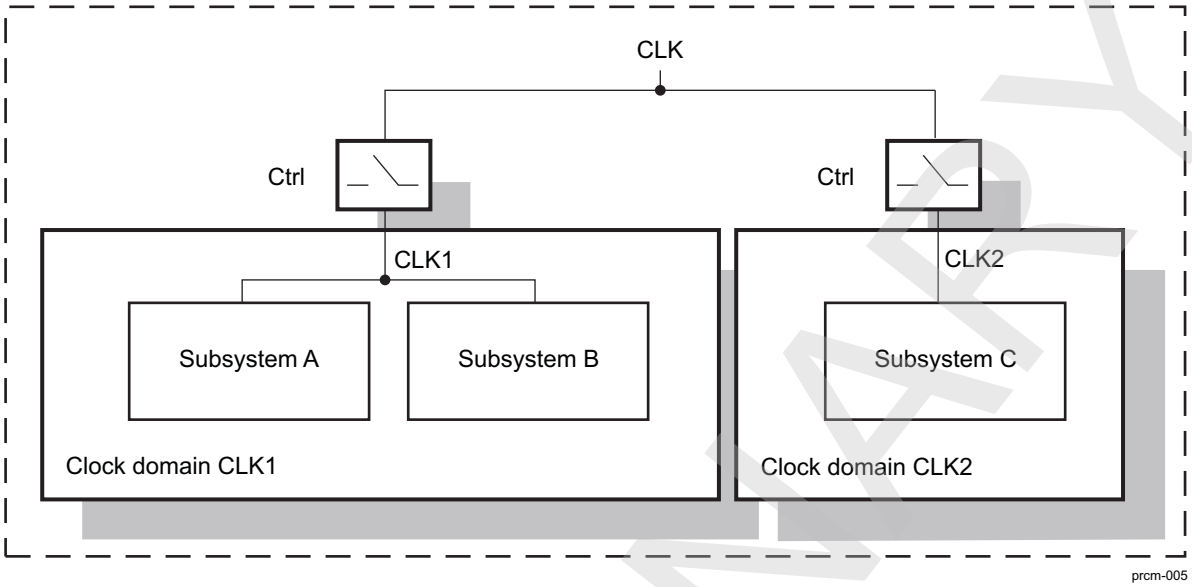


Table 3-1 lists the two possible states of the clock domain.

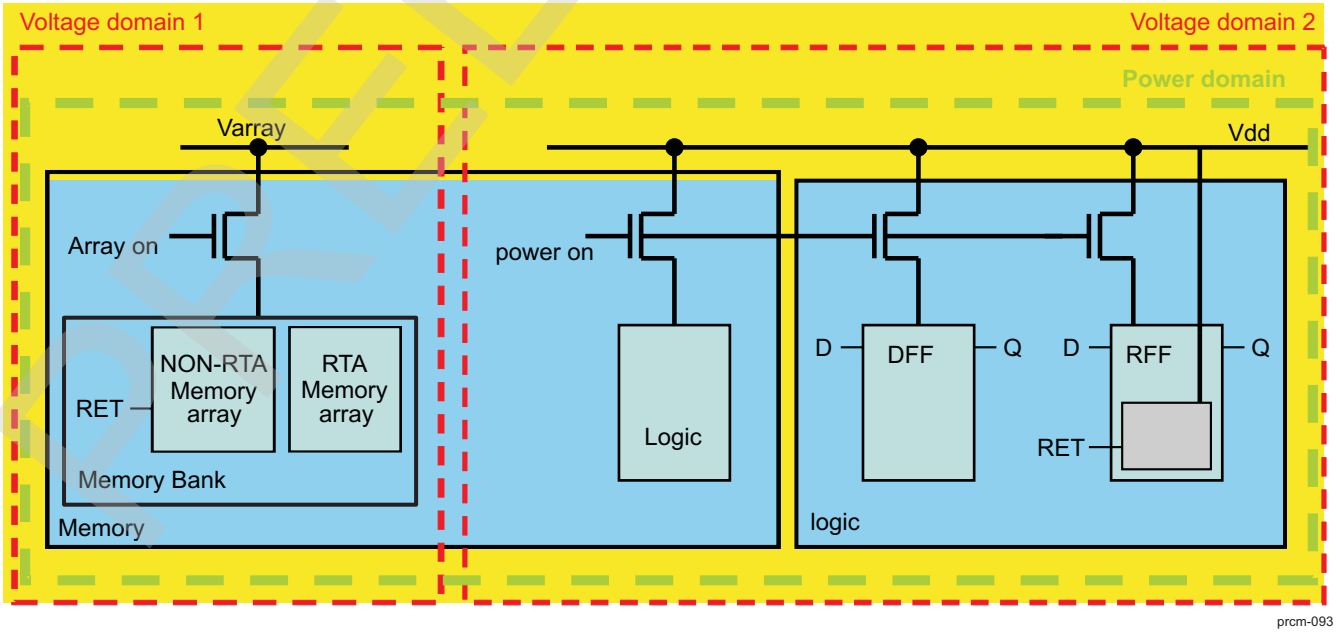
Table 3-1. States of a Clock Domain

State	Description
Active	The domain clock is running.
Idle	The domain clock is stopped or gated.

3.1.3.2 Power Domain

A power domain is a section of the device with independent and dedicated power rails (see Figure 3-6). A power domain can be turned on/off without affecting the other parts of the device.

Figure 3-6. Generic Power Domain



To minimize device power consumption, the modules are placed in power domains. All power domains embed some logic and some memory. The memory contains a memory array powered by a dedicated voltage rail (Varray + arrayon switch) and some logic powered by the same voltage rail as the power domain logic (VDD + power on switch).

The memory area contains two entities:

- Memory bank: The memory bank is composed of memory arrays. It is powered by a dedicated voltage rail and an associated power switch. The memory array within the memory bank may be of RTA (Retention-till-acces, refer to Section 3.5.2.1.4) or non-RTA type.
- Memory logic: The memory logic powered by the same voltage source as the logic area of the power domain, but has its dedicated power switch.

NOTE: The behavior of the Varray, arrayon, and power on switches can be selected by software (PWSTCTRL registers) hardwired; once the selection is made, the switches are handled automatically by the PRCM module.

The power domain logic for the CORE and the PER power domains can be split between retention flip flops (RFF) or nonretention flip flops (DFF). All other power domains embed only DFF.

A power domain can be in several power domain states: On, inactive, open/closed switch retention (OSWR, CSWR), or off.

- On or inactive (inactive is same as on but with all clocks cut): Power on is set to 1; Vdd is provided to the logic (DFF and RFF) and to the memory logic. All the logic is fully working. Depending on software settings, Varray can keep its active value or be lowered and the arrayon switch can be open or closed (depending on the power domain, this can be hardwired). As a consequence, the memory content can be accessible, retained, or lost.
- Closed-switch retention (CSWR): Power on is set to 1, Vdd is provided to the logic (DFF and RFF) and to the memory logic, but Vdd can be lowered to its retention value. The logic is not functional, but is retained. Depending on software settings, Varray can keep its active value (if needed by another memory array in another power domain), or be lowered, and the arrayon switch can be open or closed (depending on the power domain, this can be hardwired). As a consequence, the memory content can be retained or lost.
- Open-switch retention (OSWR) (CORE and PER power domains only): Power on is set to 0, Vdd, which can be lowered to its retention value, is provided only to the RFF logic. Only the RFF logic is retained. The DFF logic is lost and reset on wakeup. Depending on software settings, Varray can keep its active value (if needed by another memory array in another power domain), or be lowered, and the arrayon switch can be open or closed (depending on the power domain, this can be hardwired). As a consequence, the memory content can be retained or lost.
- Off: Power on is set to 0, Vdd is usually cut, all the logic (DFF and RFF) is lost, except for the context that has been saved in the scratchpad memory of the WKUP power domain (always on). Varray can keep its active value (if needed by another memory array sharing the same Varray voltage rail in another power domain), be lowered (if all other memory arrays sharing the same Varray voltage rail are set to be in retention), or be cut (0 V) when the entire device is in off mode. The arrayon switch is open and the memory content is lost.

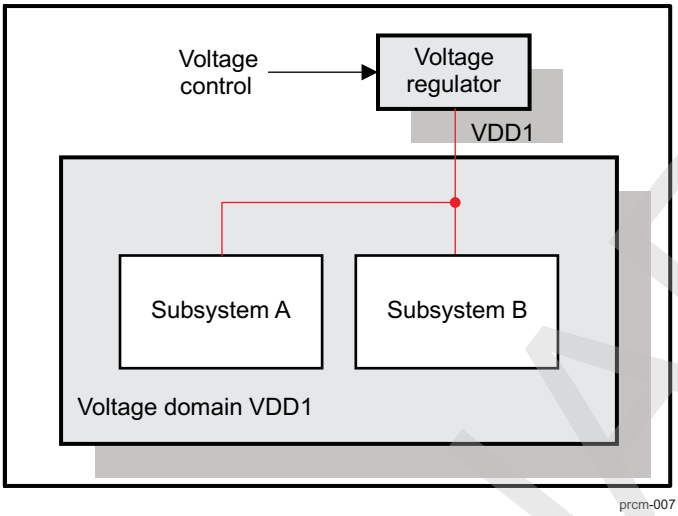
The retention state is useful for quickly switching to low-power idle mode without losing the context, and then quickly switching back to active state when necessary. In retention state, power consumption is less than in normal operating mode.

3.1.3.3 Voltage Domain

A voltage domain is a group of modules supplied by the same voltage regulator (embedded or external). The power consumption of this group can be controlled by regulating its voltage independently.

Figure 3-7 shows the voltage domain.

Figure 3-7. Generic Voltage Domain



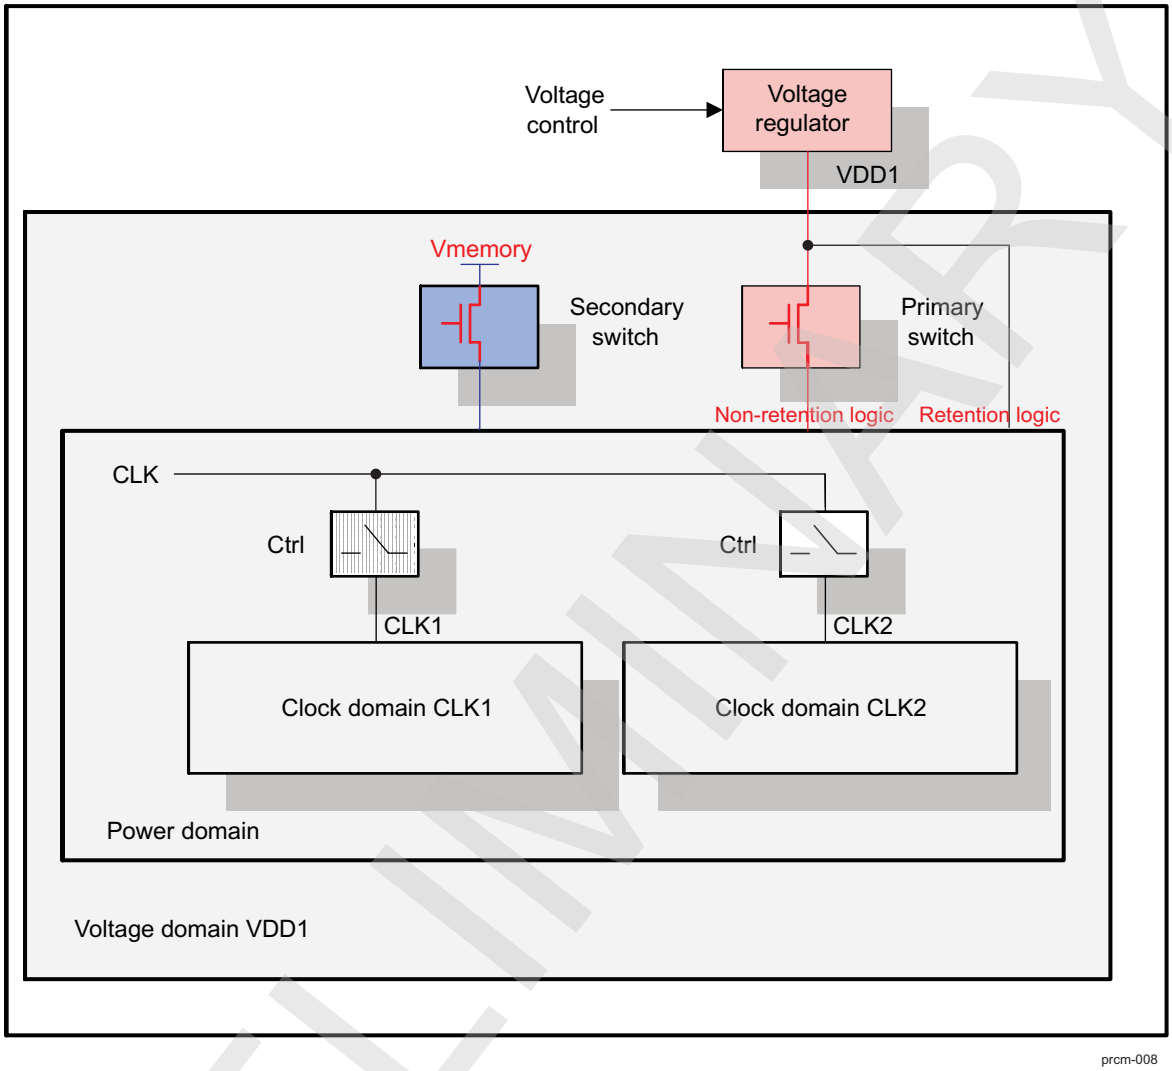
By partitioning the device into independent voltage domains, it is possible to assign different operating voltages to the different modules. The independent voltage control allows voltage scaling of device subsections to ensure that each module operates at the optimal operating voltage level based on the application performance requirements. When all modules in a voltage domain are inactive, the domain voltage can be lowered to reduce power consumption and then be switched back to normal operating voltage when a wake-up event is received.

3.1.4 Device Power-Management Architecture

The device architecture integrates the power-management architectural blocks for power-management support. It is composed of scalable/switchable voltage domains (their voltage can be controlled) and switchable power domains. Figure 3-8 shows the general hierarchical architecture scheme of the voltage, power, and clock domains.

A clock domain is a subset of a power domain. This avoids unnecessary dependencies between power domains caused by clocks covering multiple power domains. Each clock in a power domain, with an independent gating control, is a separate clock domain.

Figure 3-8. Voltage, Power, and Clock Domain Hierarchical Architecture



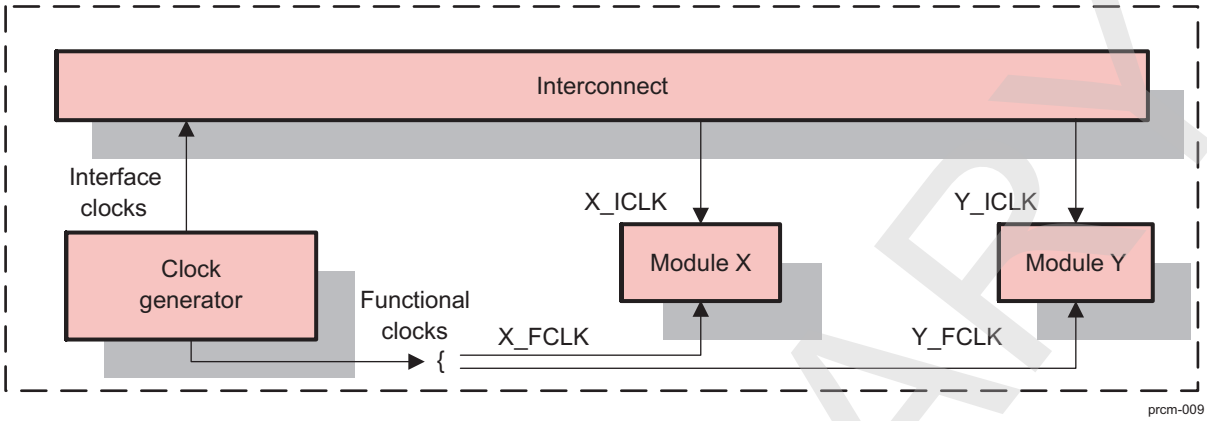
Each power domain is supplied by one or more voltage domains that can be scaled down or switched off to save power. Internal memory and logic can be put in standby (retention) mode independently. In this state, memory is not operational, but the content is retained with minimized leakage. This feature lets power consumption be reduced when the device is in sleep mode while maintaining memory contents for fast context restore. The logic and memory standby feature is software-controllable.

The device supports a clock distribution and control architecture, which is described in the following sections.

3.1.4.1 Module Interface and Functional Clocks

The clocks delivered to the modules in the device are divided into two categories: interface clocks and functional clocks (see Figure 3-9).

Figure 3-9. Functional and Interface Clocks



Interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the module interface and registers.
- A typical module has one interface clock, but it can have several.
- They are synchronous across the entire device, because the interconnect fabric is fully synchronous.
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is distributed through the device interconnect and is identified with an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or a subsystem.
- Each module can have several functional clocks, or none. A module may or may not require its functional clocks to be active (nonidle).
- Several modules can share the same functional clock signals, but the branches of the clock tree are not balanced among the modules.
- From the PRCM module standpoint, a functional clock is directly distributed to the related modules through a dedicated clock tree. It is identified with an _FCLK suffix.

NOTE: At the module level, the interface clocks are always fed by the interface clock outputs of the PRCM module. The functional clocks are fed by a PRCM functional clock output or a PRCM interface clock output. In the latter case, the functional and interface clocks of the module inherit capabilities (autoidle features) from the PRCM interface clock (see Section 3.5.3, *Clock Manager Functional Description*).

3.1.4.2 Autoidle Clock Control

The device supports an autoidle clock control scheme for the module interface clocks. With this control scheme, the PRCM module can automatically activate and deactivate the interface clock of any device module, depending on its operating mode. This scheme executes under hardware control and is transparent to the software. This scheme identifies two module types in the device: the target and the initiator modules, or subsystems.

NOTE: The functional clocks do not have the autoidle clock scheme, and the software must gate the functional clock of each module when it is not needed.

Initiator

An initiator can generate bus transactions (read, write, etc.) toward targets. It is considered active when it generates transactions. If it enters standby mode, it stops generating transactions. Because most initiators also support a target port for configuration, they are both targets and initiators. Some examples of initiators are processors, direct memory access (DMA), and memory management unit (MMU).

Target

A target is a passive module that can process bus transactions (read/write to memory-mapped registers). It is considered active when its interface clocks and some or all of its functional clocks are available so it can accept incoming transactions. A target can be put in idle mode by the PRCM module, and in this mode, its interface clock can be gated at any time. An idle module can still receive its functional clocks and generate interrupts and DMA requests. It can also generate asynchronous wake-up requests, if it is wakeup-capable.

Active, Idle, and Standby Modes

The PRCM module handles automatic clock control differently for initiator and target modules.

For the initiator module, the following hardware handshake scheme is employed:

1. The initiator, when switching from active to idle mode, signals its status to the PRCM module.
2. The PRCM module cuts off the interface clock to the initiator module.
3. When the initiator module must reactivate, it signals the PRCM module, which reactivates its functional and interface clocks.

For the target module, the following hardware handshake scheme is employed:

1. When the PRCM module confirms that the target module satisfies the idle conditions, it signals the target module.
2. The target module acknowledges the idle request of the PRCM module, depending on its idle mode internal settings (for details about idle mode settings, see the chapter in the technical reference manual for the corresponding device module):
   - If the module is set to smart-idle mode, it terminates its current operations, then acknowledges the idle request to the PRCM module.
   - If the module is set to force-idle mode, it acknowledges immediately, regardless of its state. Because pending transfers, interrupts, and DMA requests can be lost, special software care must be taken.
   - If the module is set to no-idle mode, it does not acknowledge the idle request. This forces the PRCM module to maintain the clock active.
3. The PRCM module cuts off the module clocks.
4. The target module can be awakened by the PRCM module when its wake-up conditions are satisfied (wake-up event). It activates the module clocks, and then signals the wakeup.
5. The target module acknowledges the wake-up request.
6. Some target modules can support wake-up capability. They can explicitly request the PRCM module to activate their clock.

This automatic clock control ensures reduced dynamic power consumption of the device without any associated software overhead.

3.1.5 SmartReflex Voltage-Control Overview

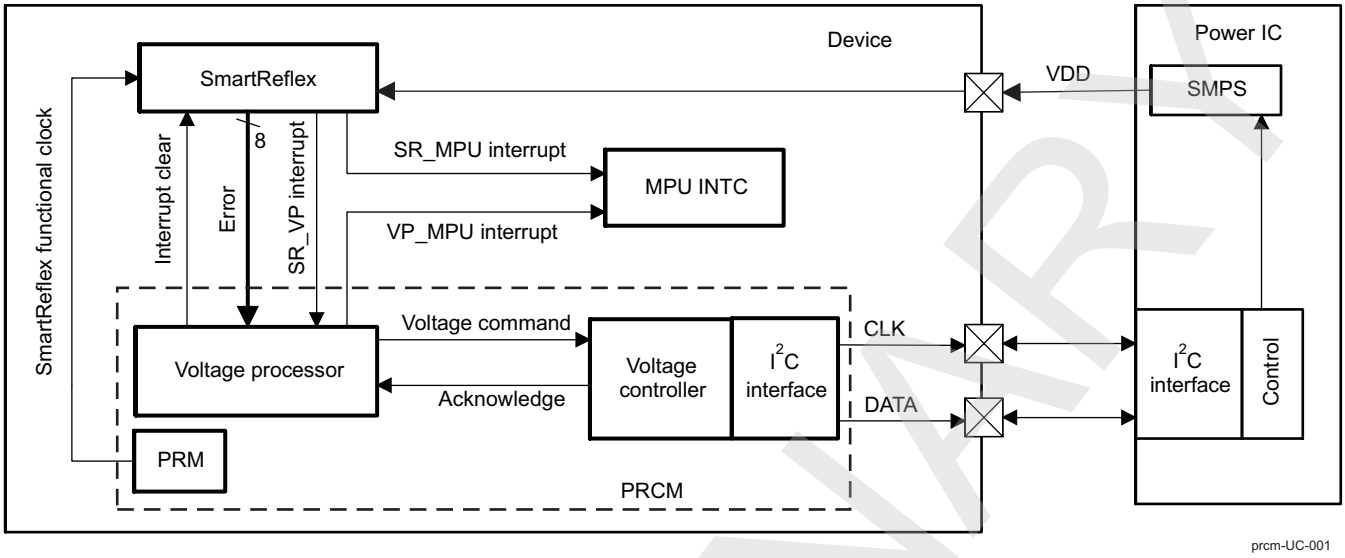
SmartReflex is a power-management technique for controlling the operating voltage of a device to reduce its active power consumption.

With SmartReflex, the power-supply voltage is adapted to the silicon performance statically (adapted to the manufacturing process of a given device) or dynamically (adapted to the temperature-induced current performance of the device). A comparison of predefined performance points to real-time on-chip measured performance determines whether to raise or lower the power supply voltage.

SmartReflex achieves optimal performance/power trade-off for all devices across the technology process spectrum and across temperature variations.

Figure 3-10 is a functional overview of the SmartReflex voltage-control architecture of the device connected to an external power integrated circuit (IC).

Figure 3-10. SmartReflex Voltage-Control Functional Overview



SmartReflex voltage control consists of the following modules:

- SmartReflex
- Microprocessor unit (MPU) interrupt controller (INTC)
- Voltage processor
- Voltage controller
- Inter-integrated circuit (I^2C?) interface
- Switch mode power supply (SMPS)

The SmartReflex module senses input voltage (VDD) and generates an error value that identifies the difference between the desired voltage and the actual value of the SMPS. This error value is set in an internal register (for software read, if necessary) and is also passed to the voltage processor.

The voltage processor converts the error value to a voltage command that defines the change in the output voltage of the SMPS required to bring it to the desired voltage level.

The voltage command is sent to the voltage controller, which passes it to the power IC through the dedicated I^2C interface. The power IC then adjusts the output voltage of the SMPS according to the command.

In this way, the SmartReflex module dynamically adjusts the SMPS voltage to compensate for voltage variations.

The device supports two operational modes for SmartReflex voltage control:

- Manual (software-controlled)
- Automatic (hardware-controlled)

3.1.5.1 Manual SmartReflex Voltage Control

In manual voltage control, the SmartReflex module interrupts the MPU when the voltage level crosses the defined voltage limits (minimum/maximum). The MPU reads the error value and determines the new voltage command to be sent to the SMPS to return the voltage to within the limits. The new voltage command is sent to the voltage controller, which passes the command to the SMPS and acknowledges its reception.

In manual control, the voltage processor is bypassed.

3.1.5.2 Automatic SmartReflex Voltage Control

In automatic voltage control, the SmartReflex module interrupts the voltage processor module when the voltage level crosses the defined voltage limits (minimum/maximum). The voltage processor reads the error value and determines the new voltage command to be sent to the SMPS to return the voltage to within the limits. The new voltage command is sent to the voltage controller, which passes the command to the SMPS and acknowledges its reception.

In automatic mode, the software does not intervene in voltage control; the entire loop is handled by the hardware modules.

3.2 PRCM Overview

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

3.2.1 Introduction

The power-management framework of the device significantly reduces dynamic power consumption and static leakage current to extend the life of the battery in the end product. This framework incorporates support for state-of-the-art power-management techniques. It ensures optimal device operation with significantly reduced power consumption. The PRCM module, which is the enhanced power-management subsystem of the device, is the central control module for the clock, reset, and power-management signals in the device.

The device supports the power-management techniques with the following features:

- Partitioning of the device into 16 voltage domains and 18 power domains
- Domain isolation that allows any combination of domain on/off states
- Clock tree with selective clock-gating conditions
- Hardware-controlled reset sequencing management
- Power, reset, and clock control hardware mechanism to manage sleep and wake-up dependencies of power domains
- Support for hardware-controlled autogating of module clocks
- Memory retention capability for preserving memory contents in low-power sleep mode
- Scalable voltage and frequency support for the processors, CORE, and peripherals for DVFS
- SmartReflex adaptive voltage scaling for real-time performance adjustments
- Support for low-power device off mode input/output (I/O) pad configuration for minimum power consumption when in off power state

The PRCM module interfaces with all the components of the device for power, clock, and reset management through power-control signals. It integrates enhanced features to let the device adapt energy consumption dynamically according to changing application and performance requirements. The innovative hardware architecture allows a substantial reduction in leakage current.

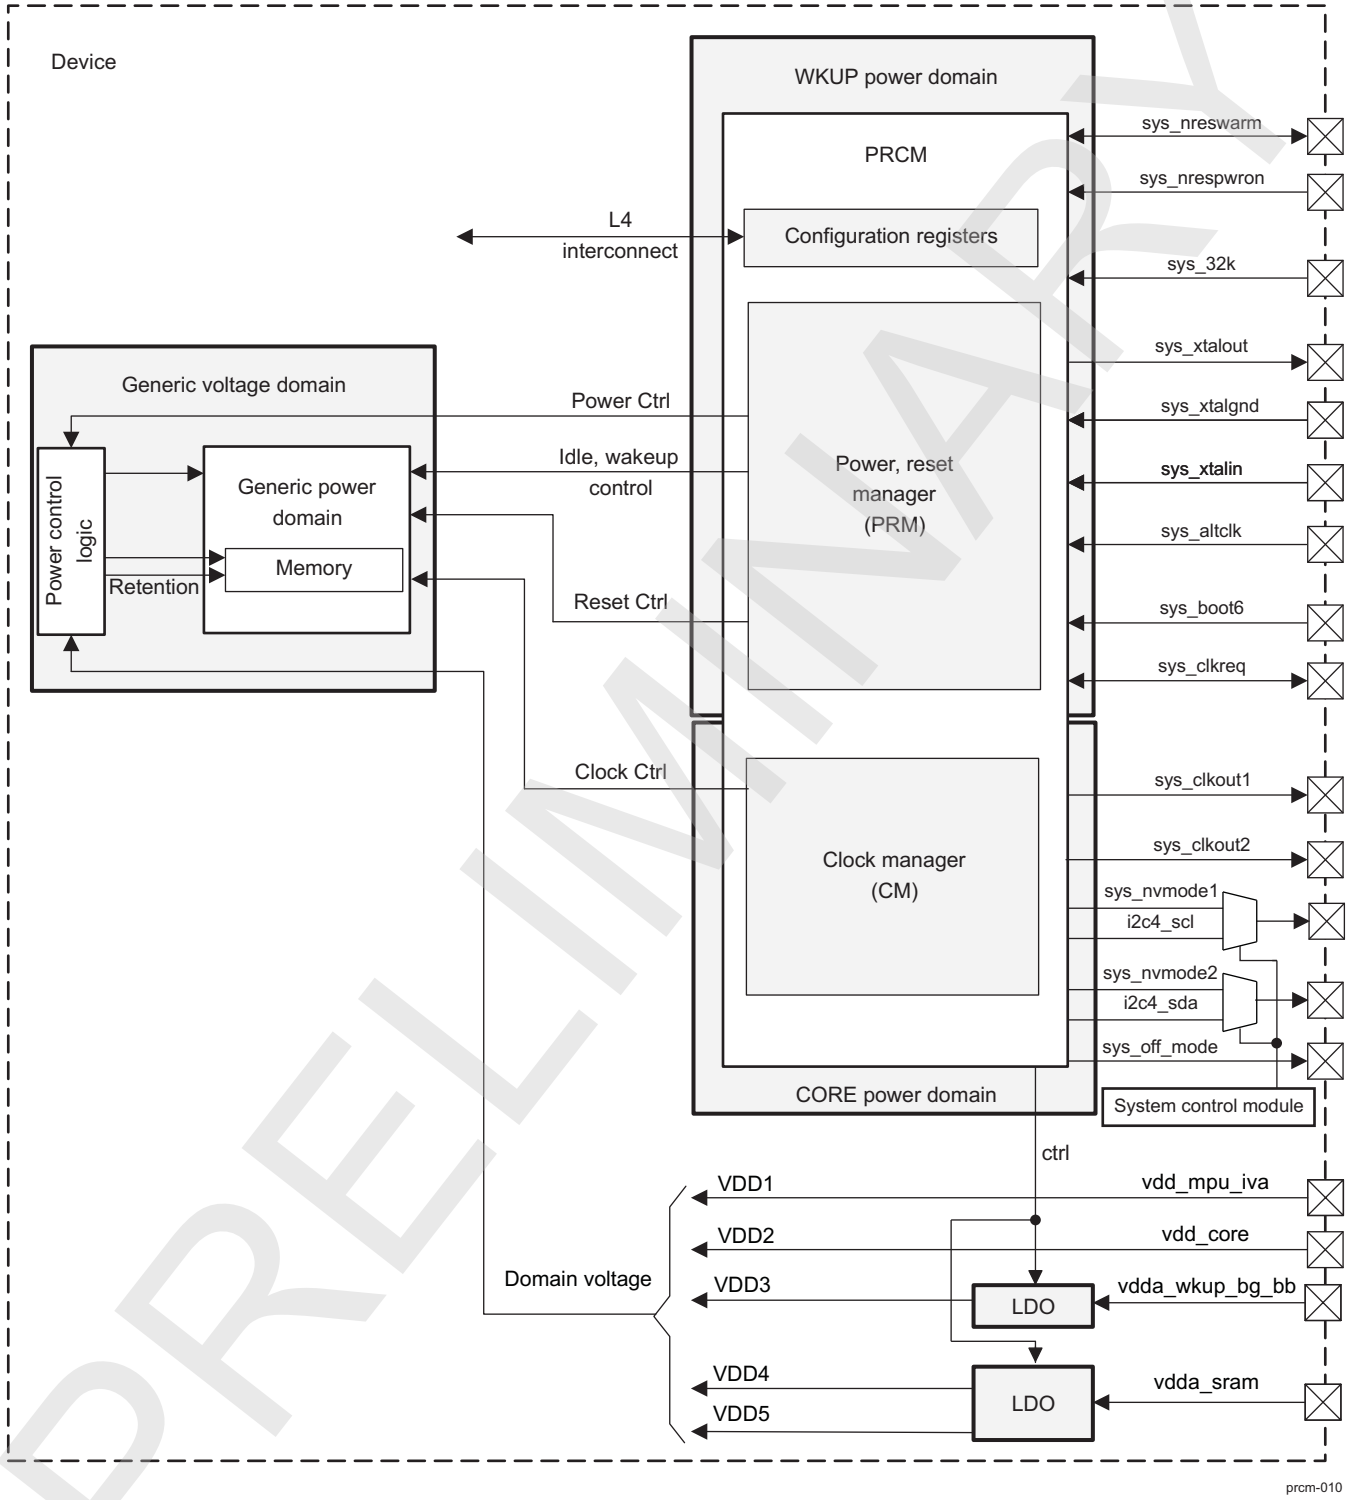
The PRCM module is composed of two main entities:

- Power reset manager (PRM): Handles power, reset, wake-up management, and system clock source control (oscillator)
- Clock manager (CM): Handles clock generation, distribution, and management

The PRCM module is fully configurable through its L4 interface port.

Figure 3-11 is an overview of the PRCM module and its internal connections with a generic power domain.

Figure 3-11. PRCM Overview



3.2.2 PRCM Features

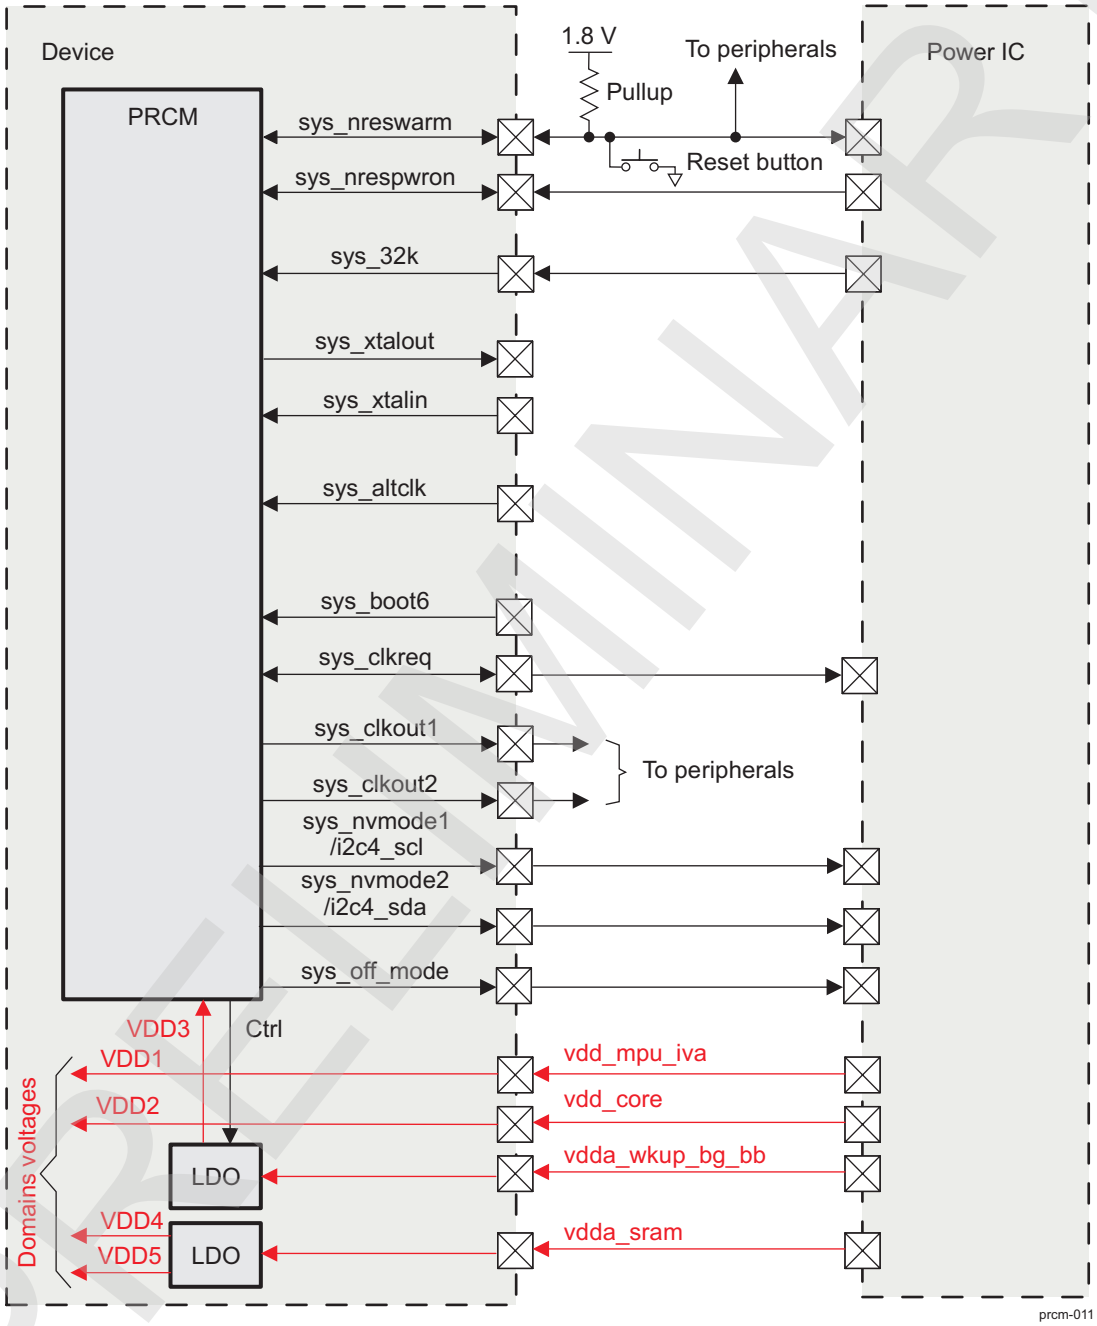
The PRCM module includes the following features:

- Managing 18 independent power domains
- Controlling two scalable and three memory-selectable voltage modes
- Handling idle/wake-up procedures
- Allowing software and partial hardware control
- Monitoring and handling wake-up events
- Controlling system clock/reset input sources
- Managing and distributing clocks and resets with high granularity
- Handling power-up sequences
- Debug and emulation features
- Controlling external supply voltage regulation through dedicated high-speed (HS) I^2C interface
- CM implementation of RFFs to support DPS

3.3 PRCM Environment

The PRCM module receives the external reset, clock, and power signals. Figure 3-12 shows the interface of the PRCM module with external reset, clock, and power sources.

Figure 3-12. PRCM Functional External Interface (Detailed View)



NOTE: In the remainder of this chapter, "power IC" refers to a peripheral power source IC that is interfaced with the device. It receives power control commands (voltage scaling and power switching) from the device and provides the necessary voltages and reset signals.

The following sections describe the interfaces for external clock, reset, and power sources.

3.3.1 External Clock Signals

The device has three external clock inputs: low frequency (sys_32k), high frequency (sys_xtalin), and an optional clock (sys_altclk). The device has two configurable clock outputs: sys_clkout1 and sys_clkout2. Figure 3-13 shows the external clock signals of the PRCM module. Table 3-2 lists the external clock signals, I/Os, and module reset values.

Figure 3-13. External Clock Interface

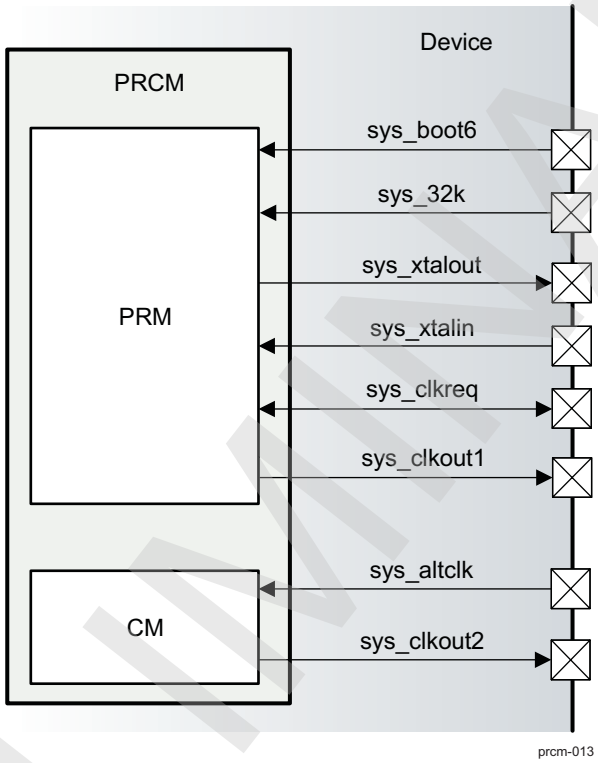


Table 3-2. External Clock Signals

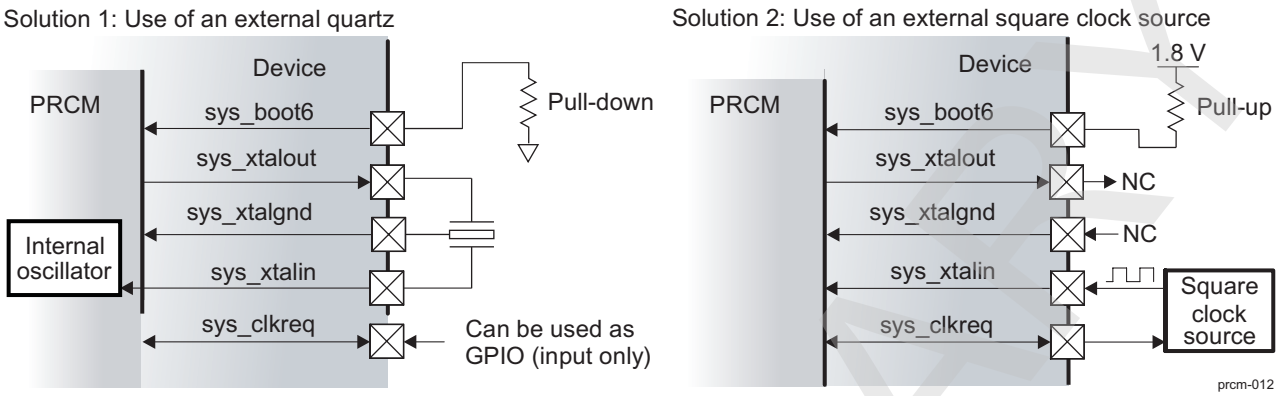
Signal	I/O [1]	Description	Module Reset Value
sys_boot6	I	Boot oscillator mode control	Unknown[2]
sys_32k	I	32-kHz clock input	Unknown[3]
sys_xtalout	O	Oscillator output	0
sys_xtalin	I	Main input clock. Crystal oscillator clock (only at 12, 13, 16.8, or 19.2 MHz) or CMOS digital clock (at 12, 13, 16.8, 19.2, 26, or 38.4 MHz).	Unknown
sys_clkreq	I/O	Clock request to/ from device for system clock	HiZ/1[4]
sys_clkout1	O	Configurable output clock 1	0
sys_altclk	I	Additional clock source selectable for universal serial bus (USB) (48 MHz), or NTSC/PAL (54 MHz)	Unknown[5]
sys_clkout2	O	Configurable output clock 2	0

(1) I = Input; O = Output
(2) sys_boot6 is either powered down or powered up
(3) Reset cannot be released without 32K stable and running
(4) sys_clkreq depends on sys_boot6
(5) sys_altclk is not enabled by default

Figure 3-14 shows the PRCM external clock sources.

Figure 3-14. PRCM External Clock Sources



The system clock source can be either of the following:

- Internal oscillator with crystal connected between sys_xtalin and sys_xtalout
- CMOS digital clock that arrives at the sys_xtalin pin

In the first option, the sys_clkreq signal is used in input mode to control sys_clkout1 and the internal clock oscillator. In the second option, the signal is used in output mode to request the external system clock.

An external pulldown or pullup tied on sys_boot6 determines whether the internal oscillator is used or an external clock source is supplied, respectively.

CAUTION

Only one clock source option can be used at a time.

An additional clock input (sys_altclk) provides a precise clock source for 54 MHz, 48 MHz, or other frequencies (for example, 59 MHz or 49.04 MHz for VDAC).

For more information about external clock signals, see Section 3.5.3.5 , *External Clock Controls*.

3.3.2 External Reset Signals

The device supports two reset signals: power-on (sys_nrespwron) and warm reset (sys_nreswarm).

sys_nrespwron is asserted at power up to reset the full logic in the device. sys_nreswarm can be activated at any time by an external device or an external reset push-button action (see Figure 3-12) to cause a global warm reset event.

Because sys_nreswarm is bidirectional, it can also drive a reset of external devices. Any global warm reset source (for example, a push-button) causes sys_nreswarm to be driven out and maintained for a limited length of time at the boundary of the device. In this way, the device and its related peripherals are reset together.

The sys_nrespwron assertion also causes assertion of sys_nreswarm.

Figure 3-15 shows the external reset signals. Table 3-3 lists the external reset signals, I/Os, and module reset values.

Figure 3-15. External Reset Signals

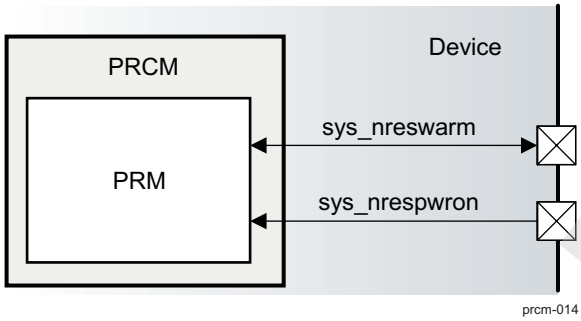


Table 3-3. External Reset Signals

Signal	I/O [1]	Description	Module Reset Value
sys_nreswarm	I/O	Warm-boot reset	1
sys_nrespwron	I	Power-on reset	Unknown

(1) I = Input; O = Output

NOTE: Depending on the power IC used, sys_nrespwron must be kept asserted until the voltage and power domains are ramped up. At the PRCM boundary, a sys_nrespwron pulse of 1 ns resets the device.

sys_nreswarm assertion is asynchronously sampled in the PRM. It is kept internally asserted until the voltage and power domains are ramped up.

3.3.3 External Power Signals

The power control signals let the PRCM module control the device voltage levels. The voltage level of the scalable voltage sources in the external power IC can be scaled by sending commands to the power IC through this interface. The PRCM module can also command the power IC to switch the device voltages off when the device is in off mode and activate them when it wakes up.

Figure 3-16 shows the power control interface for the external power IC. Table 3-4 lists the signals, I/Os, and module reset values for the external power IC.

Figure 3-16. Power Control Interface for External Power IC

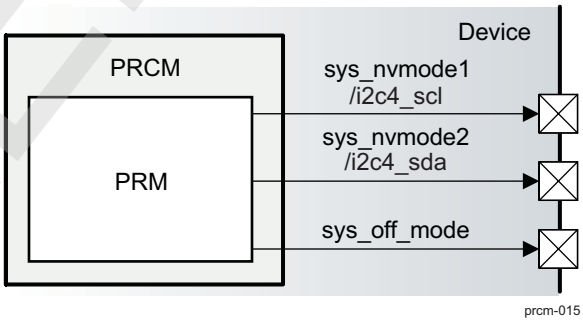

Table 3-4. Power Control Interface

Signal	I/O [1]	Description	Module Reset Value
sys_nvmode1/i2c4_scl	O	Commands the external power IC for control of VDD1 and VDD2 voltages Shared by the VMODE interface and the SmartReflex dedicated I^2C interface	0x1

(1) I = Input; O = Output

Table 3-4. Power Control Interface (continued)

Signal	I/O [1]	Description	Module Reset Value
sys_nvmode2/i2c4_sda	O	Commands the external power IC for control of VDD1 and VDD2 voltages. Shared by the VMODE interface and the SmartReflex dedicated I^2C interface	0x1
sys_off_mode	O	Requests the external power IC to switch the device voltage level according to the device power status	0x0

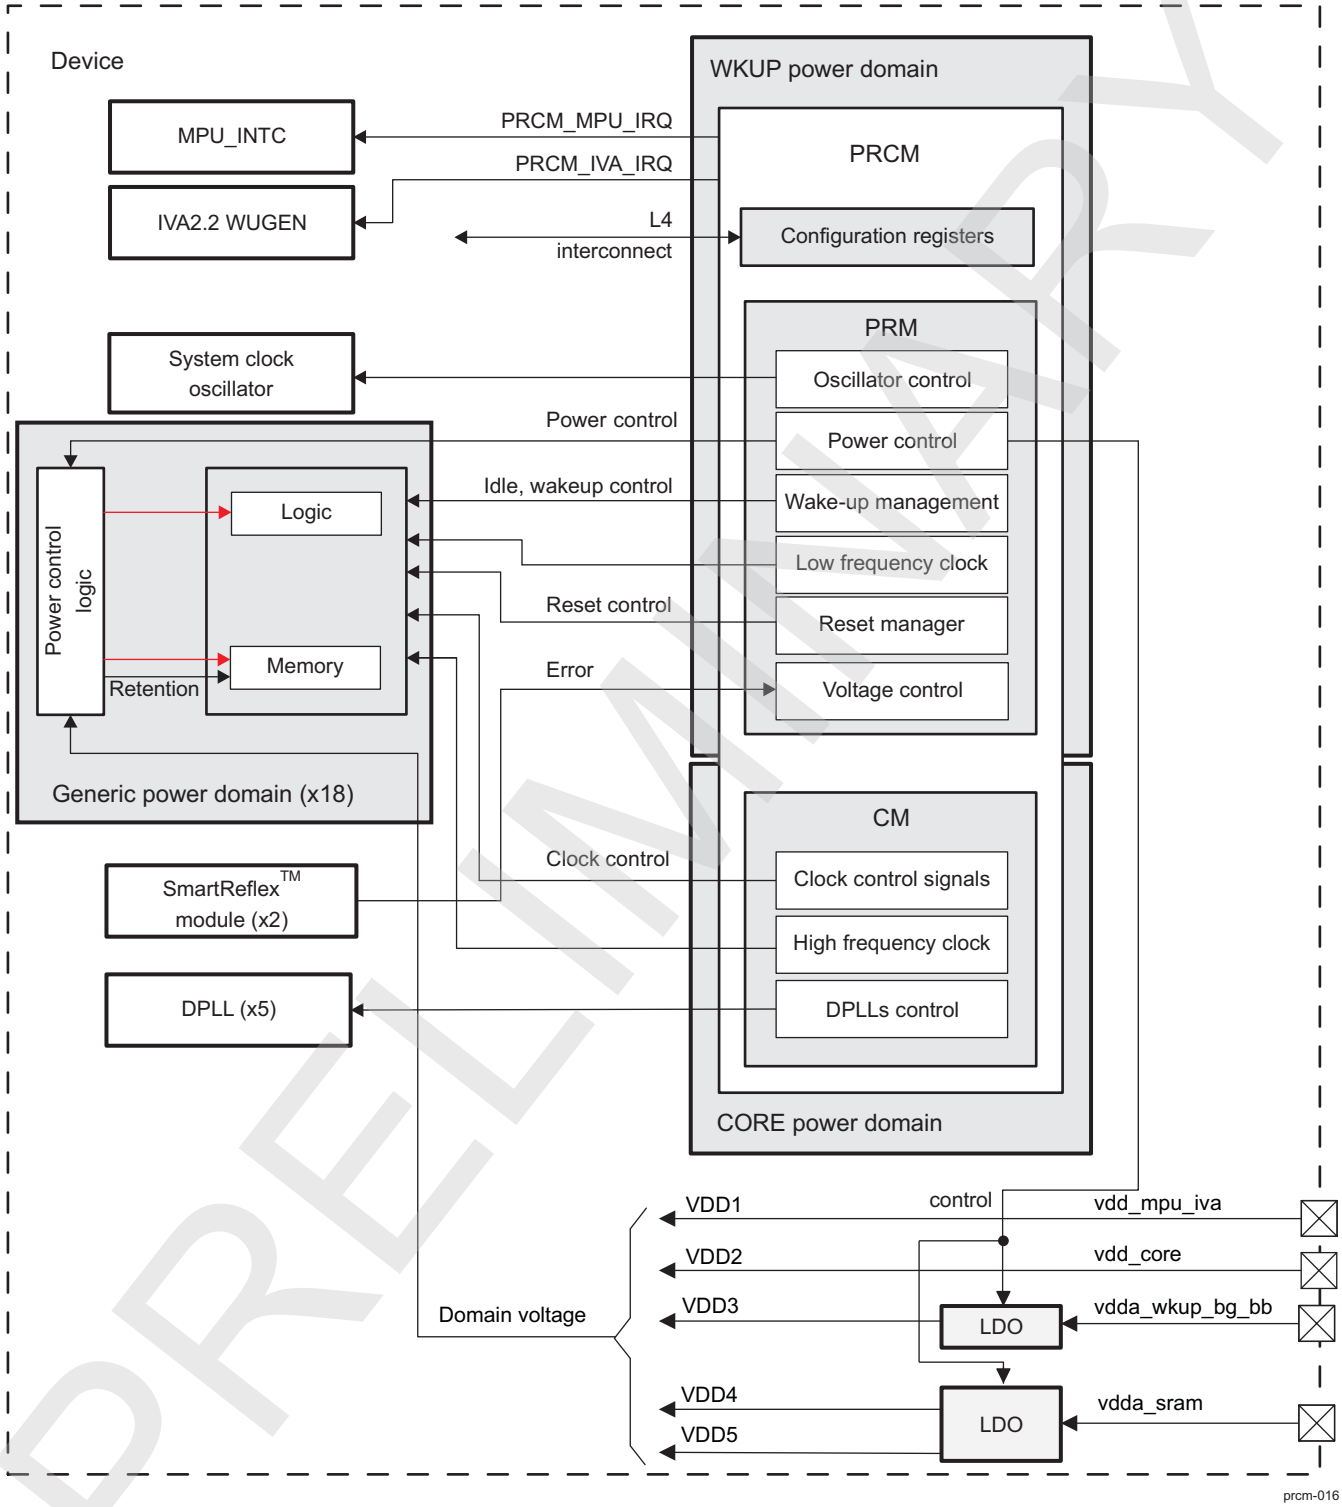
3.4 PRCM Integration

The PRCM internal registers can be accessed for configuration and controlled through the WKUP L4 interconnect. In addition to the L4 interconnect, the PRCM internal module interface contains the following:

- A set of signals for idle/wake-up control for each module
- Clocks and reset signals
- Power control signals (switches and memories) to the power domains
- Interrupts to the MPU subsystem and IVA2.2 subsystem INTCs
- Voltage error commands from the SmartReflex modules
- Digital phase-locked loop (DPLL) control commands for recalibration and bypass
- System clock oscillator control for device-level sleep/wake-up transitions

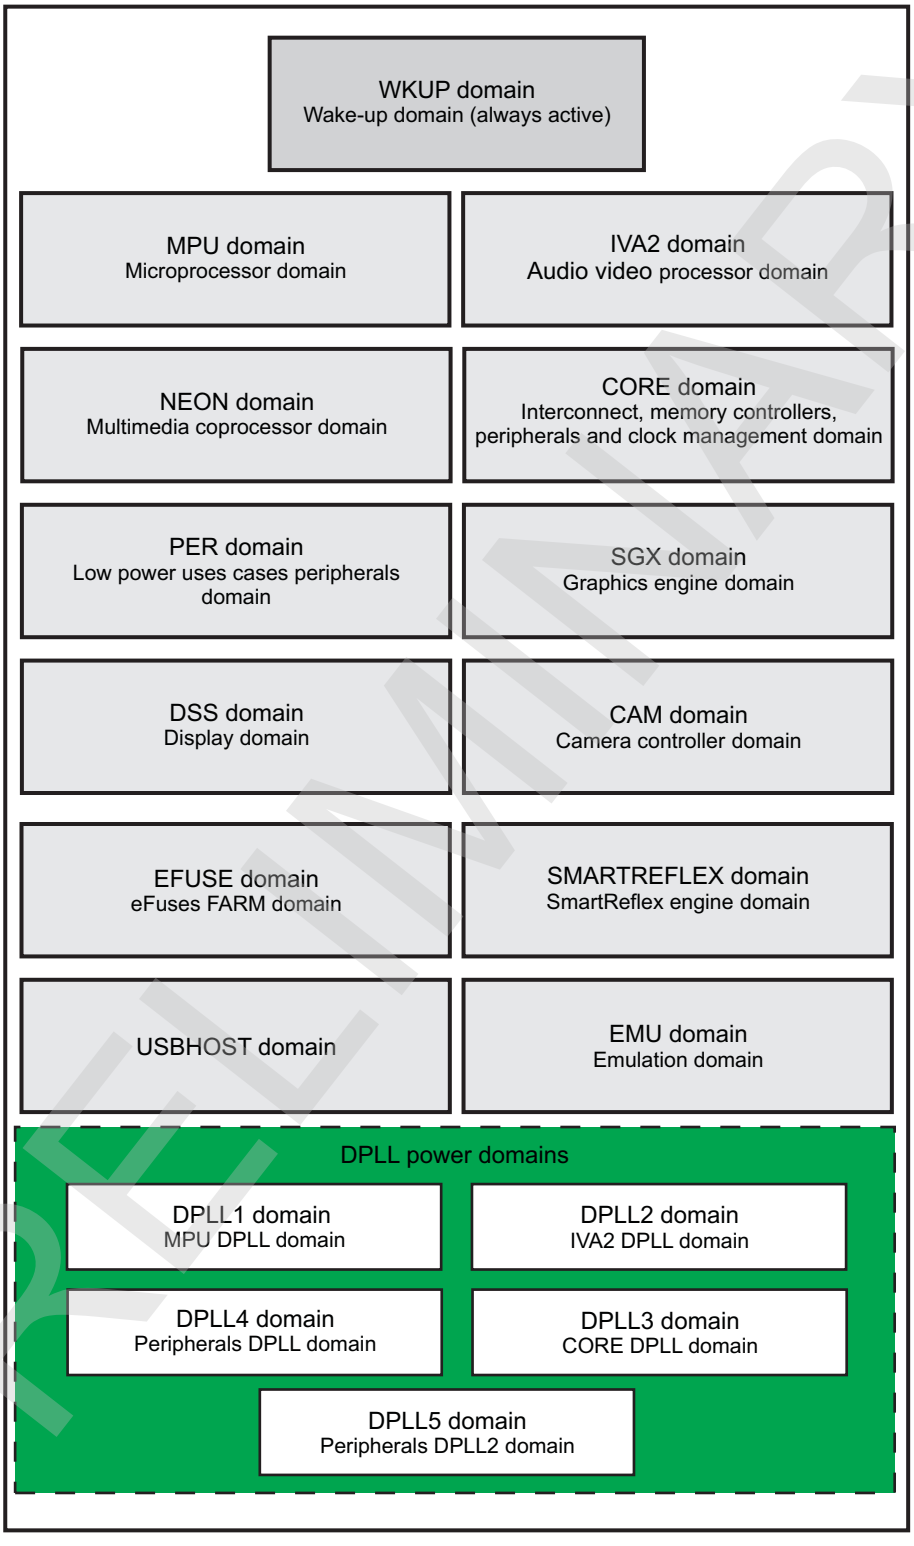
Figure 3-17 shows details of the control interface to a generic power domain.

Figure 3-17. PRCM Integration



To significantly reduce leakage in sleep modes (SLM strategy) and to optimize active power consumption (DPS strategy), the device is segmented into 18 power domains (see Figure 3-18).

Figure 3-18. Device Power Domains



Each power domain is fed through an independent switch controlled by the PRM module. In this way, depending on the application scenario, unused parts (domains) can be switched off or put in retention state while others remain active.

3.4.1 Power-Management Scheme, Reset, and Interrupt Requests

3.4.1.1 Power Domain

The PRCM module is in two power domains (see Table 3-5).

Table 3-5. PRCM Power Domains

PRCM Subsystem Modules	Power Domain
PRM	WKUP
CM	CORE

The PRM module is in the WKUP power domain, which is continuously active. It is composed of the logic that must be permanently supplied to manage domain power-state transitions and detect wake-up events.

The CM module is in the CORE power domain, which can be activated and deactivated according to the requirements of the executing applications.

3.4.1.2 Resets

The PRM and CM modules are reset by independent reset signals (see Table 3-6).

Table 3-6. PRCM Reset Signals

PRCM Subsystem	Reset Signal
PRM	PRM_RSTPWRON
CM	CM_RSTPWRON_RET

The PRM module is reset by the cold reset signal PRM_RSTPWRON. The CM module is reset by assertion of the CM_RSTPWRON_RET signal.

The CM logic is reset on:

- Any global cold reset
- A CORE power domain transition from off to on

The PRM logic is reset on any global cold reset.

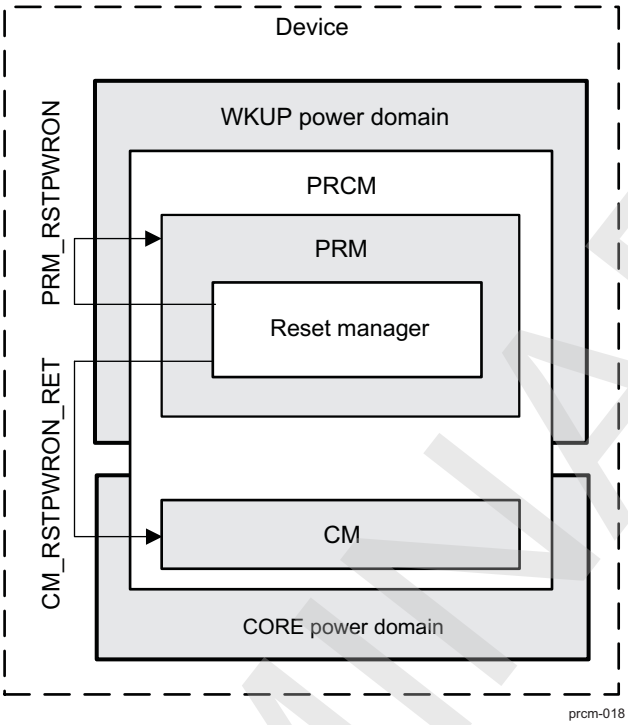
CM and PRM registers that are sensitive to a warm reset are also reset when a global warm reset occurs. However, the CM and PRM logic is not reset.

NOTE: At global cold reset:

- Only the device finite state-machine (FSM) in the PRM operates on the 32-kHz clock, and it is released from reset on the release of the global reset.
- PRM logic operates on the system clock and is released from reset on release of the reset PRM_RSTPWRON.

Figure 3-19 shows the PRCM reset signals.

Figure 3-19. PRCM Reset Signals



3.4.1.3 Interrupt Requests

The PRCM module can generate two interrupts:

- PRCM_MPU_IRQ: Mapped to the MPU INTC module (M_IRQ_11 interrupt line)
- PRCM_IVA_IRQ: Mapped to the IVA2.2 WUGEN module (IVA2_IRQ[12] interrupt line)

3.5 PRCM Functional Description

3.5.1 PRCM Reset Manager Functional Description

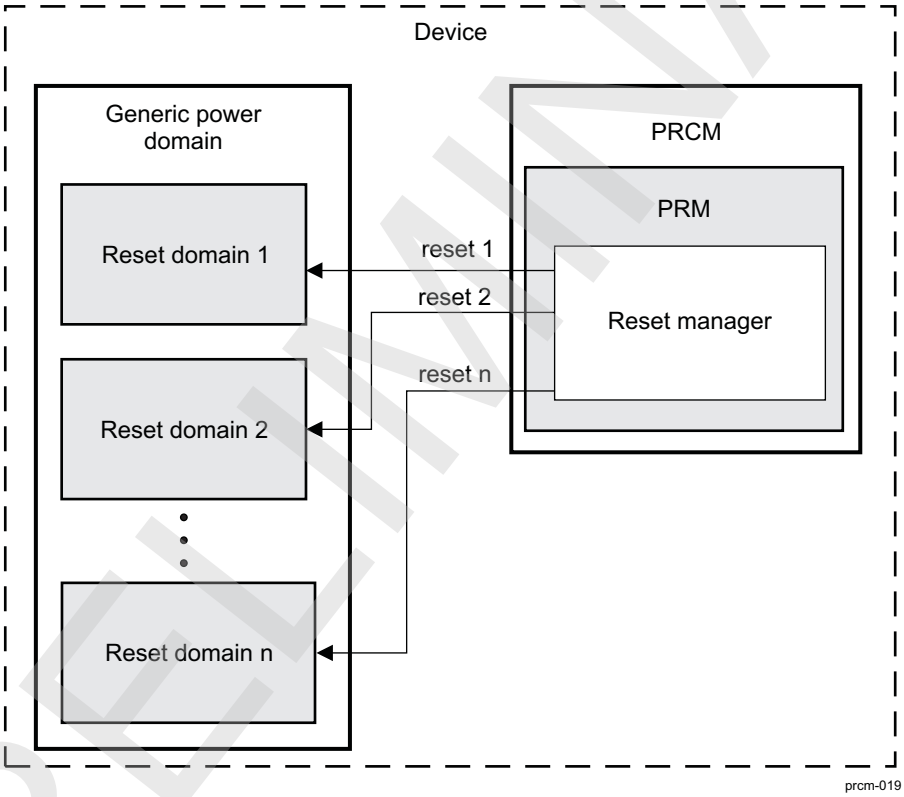
3.5.1.1 Overview

The PRCM module manages the reset of all modules in the device. Resets are distributed across the 18 independent power domains (including DPLLs and SmartReflex modules).

In each power domain, one or more reset domains are defined. A reset domain is defined by a unique reset signal that originates from the reset manager and is connected to one or more modules of the device. All the connected modules of the reset domain are reset simultaneously when the reset signal is asserted. Independent control of these reset domains allows sequencing the release of resets and ensures a safe reset of the entire power domain.

Figure 3-20 is an overview of the reset manager interface with a generic power domain in the device.

Figure 3-20. Reset Manager Interface With Generic Power Domain



Resets can be generated by hardware sources or software control. For a module that can be reset by software control, a software-reset bit is implemented in its <module name>_SYSCONFIG configuration register. Software reset has the same effect on the module logic as a hardware reset.

Special reset control is available to reset specific reset domains when the device operates under emulation control.

NOTE: All reset assertion is asynchronous, and all reset signals are active low, except for the DPLL reset signals, which are active high.

3.5.1.2 General Characteristics of Reset Signals

Reset signals can be categorized based on three criteria:

- Scope
- Occurrence
- Source type

3.5.1.2.1 Scope

A reset signal can be categorized according to its scope (the area of the device affected by that reset):

- Global reset: Affects the entire device; all modules are reset. Generally, occurs when the device powers up or an abnormal operation is detected (the eFuse bad device is detected, etc.).
- Local reset: Affects one power or reset domain. Generally, when a power domain transitions from off mode to active mode, or when a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

3.5.1.2.2 Occurrence

A reset signal can be categorized depending on when the reset occurs:

- Cold reset: Occurs only on device power up or in certain emulation modes. The cold reset is a global reset that affects every module in the device. It usually corresponds to the initial power-on reset.
- Warm reset: Occurs when the device is in normal operating state. The warm reset is also a global reset, but it does not affect all the modules in the device. Usually, the device does not require a complete reboot on a warm reset. Several reset sources, such as the global software reset and the watchdog reset, are warm resets.

Modules that behave differently in cold reset and warm reset have two reset signals: RST and PWRON_RST. These reset signals reconstruct warm reset and cold reset in modules that require them.

For a global warm reset, the PRCM module performs the following sequence:

1. Applies a warm reset on all the modules, including modules built with RFFs.
2. Applies a warm reset on the external modem interface.
3. Drives the sys_nreswarm reset output low and holds it for a specified length of time (programmed in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).
4. All ongoing transactions on the voltage control I^2C interface (I2C4 module) are aborted, and the external power IC is expected to return to nominal voltage values on receiving a sys_nreswarm reset.
5. All power domains that are in off power mode are switched to on power mode.

A global warm reset does not apply to the following modules of the device:

- SDRC
- System control module (SCM) (I/O control)
- Part of PRM and CM registers (see note below)
- 32-kHz synchronization timer
- DPLL3 (see Section 3.5.1.9.2)
- Emulation modules
- eFuse farm

NOTE: For information about the PRCM registers affected by the global warm reset, see the register mapping summary tables in Section 3.8, *PRCM Register Manual*.

3.5.1.2.3 Source Type

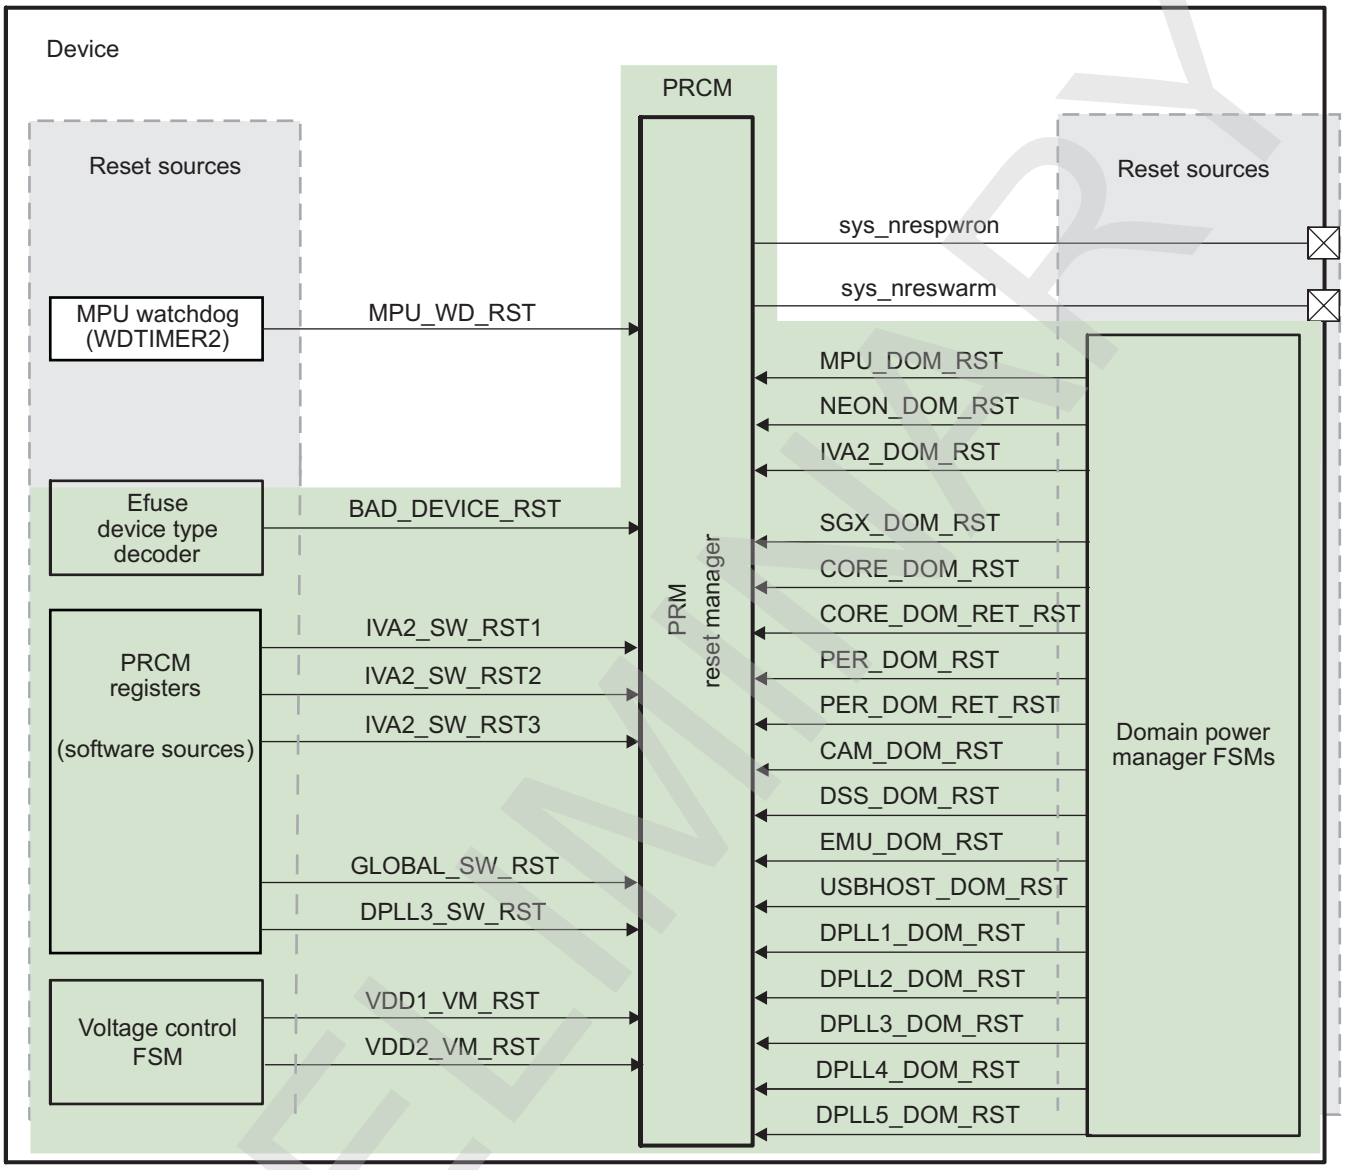
A reset can be categorized depending on whether it is software-controlled or hardware-triggered:

- Software reset: Triggered by setting a bit in a configuration register of the PRCM module
- Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

3.5.1.3 Reset Sources

Figure 3-21 is an overview of the reset sources.

Figure 3-21. Reset Sources Overview



*The green region in the figure represents the boundary of the PRCM.

prcm-020

3.5.1.3.1 Global Reset Sources

Table 3-7 lists the global reset sources of the device. The global reset source signals received by the reset manager trigger the reset of all the device modules. For all hardware reset signals, the source of the reset is identified; for the software reset signals, the reset triggering bit is identified.

Table 3-7. Global Reset Sources

Type [1]	Name	Source/Control	Description
H/C	sys_nrespwron	Input pin	The entire device is reset on power up.
H/C	BAD_DEVICE_RST	PRCM	Asserted when during the power-up sequence the device is identified as bad, after reading eFuses
H/W	sys_nreswarm	Bidirectional pin	External hardware warm reset

[1] H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

Table 3-7. Global Reset Sources (continued)

Type [1]	Name	Source/Control	Description
H/W	MPU_WD_RST	WDTIMER2	MPU watchdog timer overflow reset
S/W	GLOBAL_SW_RST	PRCM.PRM_RSTCTRL[1] RST_GS	Global software reset
H/W	VDD1_VM_RST	PRCM	Asserted by the voltage manager FSMs when no response from the power IC is received during wake-up transition from retention or off mode
H/W	VDD2_VM_RST	PRCM	
S/W	DPLL3_SW_RST	PRCM.PRM_RSTCTRL[2] RST_DPLL3	Local cold reset for DPLL3 and a global cold reset to the device

3.5.1.3.2 Local Reset Sources

Table 3-8 lists the local reset sources of the device. A local reset source signal received by the reset manager resets only some of the device modules.

Table 3-8. Local Reset Sources

Type [1]	Name	Source/Control	Description
H/C	CORE_DOM_RET_RST	PRCM	Asserted only for a power domain state transition from off to active state
H/C	USB_DOM_RET_RST	PRCM	
H/C	PER_DOM_RET_RST	PRCM	
H/C	MPU_DOM_RST	PRCM	Asserted for any power domain transition from off or retention state to active state
H/C	IVA2_DOM_RST	PRCM	
H/C	NEON_DOM_RST	PRCM	
H/C	SGX_DOM_RST	PRCM	
H/C	CORE_DOM_RST	PRCM	
H/C	PER_DOM_RST	PRCM	
H/C	CAM_DOM_RST	PRCM	
H/C	DSS_DOM_RST	PRCM	
H/C	DPLL1_DOM_RST	PRCM	
H/C	DPLL2_DOM_RST	PRCM	
H/C	DPLL3_DOM_RST	PRCM	
H/C	DPLL4_DOM_RST	PRCM	
H/C	DPLL5_DOM_RST	PRCM	
S/W	IVA2_SW_RST1	PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2	IVA2.2: DSP reset control
S/W	IVA2_SW_RST2	PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2	IVA2.2: MMU reset control and video sequencer hardware accelerator reset control
S/W	IVA2_SW_RST3	PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2	Video sequencer reset control

(1) H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

NOTE:

- For power domains with <domain name>_DOM_RST and <domain name>_DOM_RET_RST, the reset sources are asserted together when the domain transitions from off to on power state, whereas only <domain name>_DOM_RET_RST is asserted on a global or local warm reset.
- Because the modem reset signals are not supported in the device stand-alone configuration, they are not discussed in this section.

3.5.1.4 Reset Distribution

Each power domain can contain one power-on reset (RSTPWRON) and one or more reset (RST) signals. These signals behave as follows:

- On any global or local cold reset, RST and RSTPWRON are asserted.
- On any global or local warm reset, only RST is asserted.

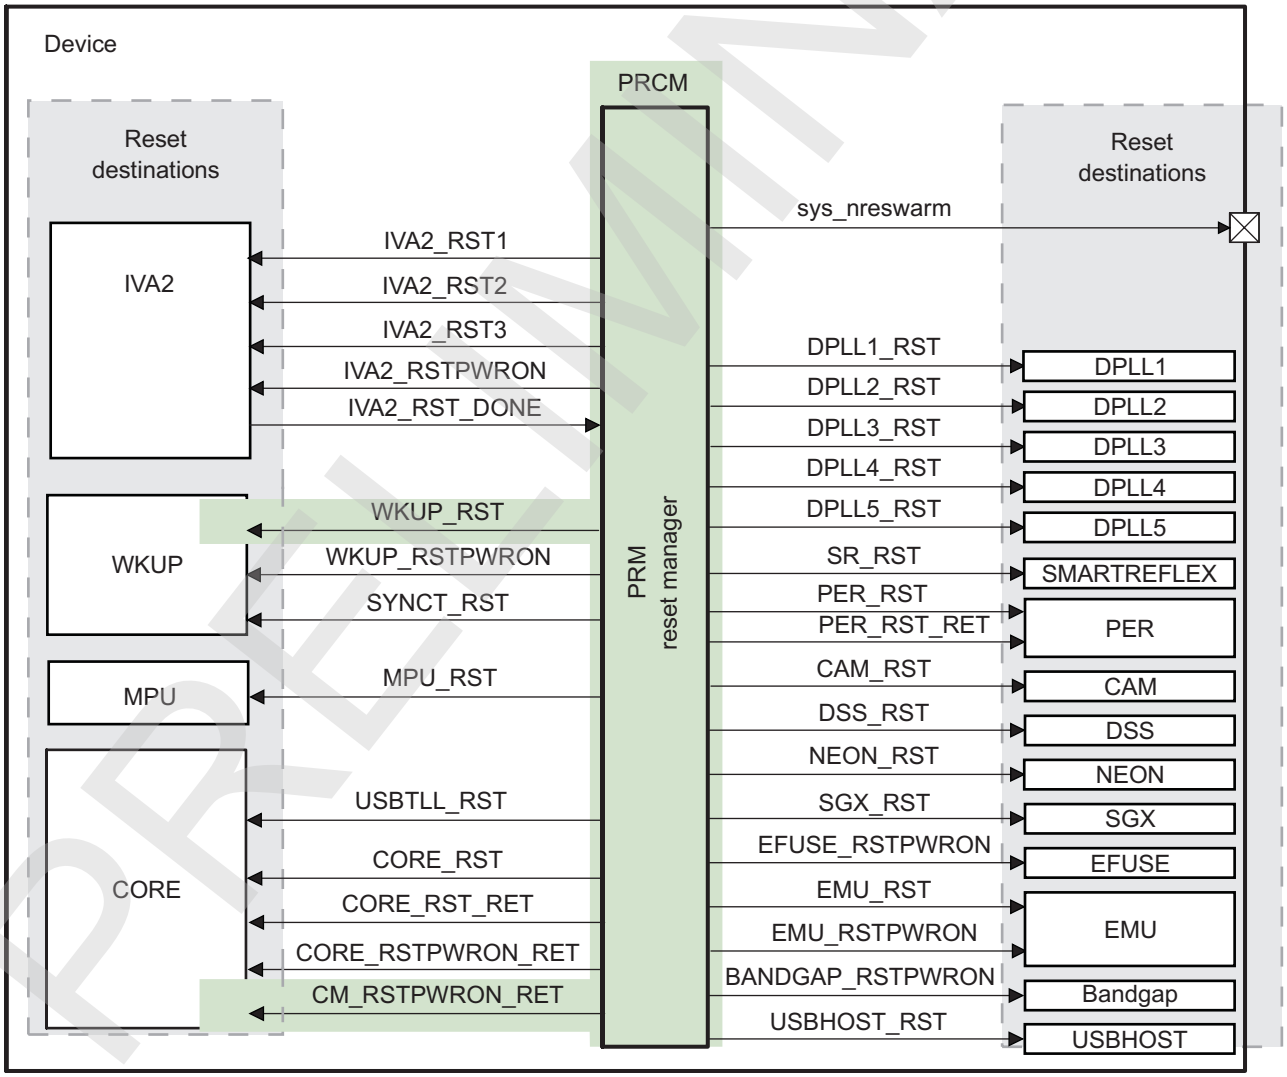
The CORE power domain receives two additional retention logic reset signals: retention reset (RST_RET) and power-on retention reset (RSTPWRON_RET). These signals behave as follows:

- On any global cold reset or wakeup from off state to active state, RST_RET and RSTPWRON_RET are asserted.
- On any global warm reset, only RST_RET is asserted.
- On wakeup from retention state, these signals are not asserted.

The IVA2 power domain outputs the IVA2_RST_DONE signal, which handles the synchronous reset scheme of the IVA2.2 subsystem.

Figure 3-22 shows the reset distribution among the 18 power domains.

Figure 3-22. Reset Destination Overview



*The green region in the figure represents the boundary of the PRCM

prcm-021

3.5.1.5 Power Domain Reset Descriptions

3.5.1.5.1 MPU Power Domain

The MPU power domain has two reset input signals and one reset output signal (see Table 3-9).

Table 3-9. MPU Power Domain Reset Signal

Name	I/O [1]	Source/Destination [2]	Reset Domain
MPU_RST	I	PRM	Resets the MPU processor core and the asynchronous bridge in the MPU power domain

(1) I = Input; O = Output
(2) Source for an input signal and destination for an output signal

3.5.1.5.2 NEON Power Domain

The NEON power domain has one reset input signal (see Table 3-10).

Table 3-10. NEON Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
NEON_RST	I	PRM	Resets the NEON coprocessor

(1) I = Input; O = Output

3.5.1.5.3 IVA2 Power Domain

The IVA2 power domain has four inputs and one output reset signal (see Table 3-11).

Table 3-11. IVA2 Power Domain Reset Signals

Name	I/O [1]	Source/Destination [2]	Reset Domain
IVA2_RST1	I	PRM	Resets the IVA2.2 DSP and part of the two asynchronous bridges in the IVA2 power domain
IVA2_RST2	I	PRM	Resets the IVA2.2 MMU
IVA2_RST3	I	PRM	Resets the video sequencer module
IVA2_RSTPWRON	I	PRM	Performs a power-on reset on the IVA2.2 subsystem. Active on a cold reset only.
IVA2_RSTDONE	O	PRM	Release condition of the IVA_RST1 and RST2. Generated by the IVA2.2 subsystem at the end of the initialization sequence.

(1) I = Input; O = Output
(2) Source for an input signal and destination for an output signal

3.5.1.5.4 CORE Power Domain

The CORE power domain has eight inputs and one output reset signal (see Table 3-12).

Table 3-12. CORE Power Domain Reset Signals

Name	I/O [1]	Source/Destination [2]	Reset Domain
CORE_RST	I	PRM	Resets parts of the three asynchronous bridges, MPU INTC, IVA2.2 WUGEN, interconnects, ICR, modem INTC, SAD2D, mailboxes, GPMC, OCM, UART[1,2], HDQ, HS USB, I2C[1..3], McBSP 1 and 5, McSPI [1..3], MMC[1..3], GPTIMER[10,11]
CORE_RST_RET	I	PRM	Resets part of the SDRC, SDMA, SMS, MPU INTC, and IVA2 WUGEN
CORE_RSTPWRON_RET	I	PRM	Resets part of the SDRC and SCM
CM_RSTPWRON_RET	I	PRM	Resets the clock manager

(1) I = Input; O = Output
(2) Source for an input signal and destination for an output signal

Table 3-12. CORE Power Domain Reset Signals (continued)

Name	I/O [1]	Source/Destination [2]	Reset Domain
USBTLL_RST	I	PRM	Resets the USB TLL asynchronously

The CM logic is reset on:

- Any global cold reset
- A CORE power domain transition from off to on

Because the CM logic is not reset in this case, CM registers that are sensitive to a warm reset must also be reset synchronously with the L4 clock when a global warm reset occurs.

3.5.1.5.5 DSS Power Domain

The DSS power domain has one reset input signal (see Table 3-13).

Table 3-13. DSS Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
DSS_RST	I	PRM	Resets the entire display subsystem

(1) I = Input; O = Output

3.5.1.5.6 CAM Power Domain

The CAM power domain has one reset input signal (see Table 3-14).

Table 3-14. CAM Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
CAM_RST	I	PRM	Resets the entire camera subsystem

(1) I = Input; O = Output

3.5.1.5.7 USBHOST Power Domain

The USBHOST power domain has one reset input signal (see Table 3-15).

Table 3-15. USBHOST Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
USBHOST_RST	I	PRM	Resets the entire HS USB host subsystem

(1) I = Input; O = Output

3.5.1.5.8 SGX Power Domain

The SGX power domain has one reset input signal (see Table 3-16).

Table 3-16. SGX Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
SGX_RST	I	PRM	Resets the entire SGX subsystem

(1) I = Input, O = Output

3.5.1.5.9 WKUP Power Domain

The WKUP power domain has three reset input signals and two reset output signals (see Table 3-17).

Table 3-17. WKUP Power Domain Reset Signals

Name	I/O [1]	Source/Destination [2]	Reset Domain
WKUP_RST	I	PRM	Resets the GPTIMER1, WDTIMER2, GPIO 1
WKUP_RSTPWRON	I	PRM	Resets the wake-up control module
MPU_WD_RST	O	PRM	Global warm reset for PRM. Generated by WDTIMER2.

(1) I = Input; O = Output
(2) Source for an input signal and destination for an output signal

The PRM logic is reset on any global cold reset. Because the PRM logic is not reset in this case, PRM registers that are sensitive to a warm reset must also be reset synchronously with the system clock when a global warm reset occurs.

3.5.1.5.10 PER Power Domain

The PER power domain has two reset input signals (see Table 3-18).

Table 3-18. PER Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
PER_RST	I	PRCM	Resets the UART[3, 4], McBSP[2,3,4], GPTIMER[2,..,9], WDTIMER3 modules
PER_RST_RET	I	PRCM	Resets the GPIO [2,..,6] modules

(1) I = Input; O = Output

3.5.1.5.11 SmartReflex Power Domain

The SmartReflex power domain has one reset input signal (see Table 3-19).

Table 3-19. SmartReflex Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
SR_RST	I	PRCM	Resets the SR1 and SR2 modules

(1) I = Input; O = Output

3.5.1.5.12 DPLL Power Domains

The DPLL power domains for DPLL1, DPLL2, DPLL3, DPLL4 and DPLL5 each have one reset input signal.

Table 3-20. DPLL Power Domain Reset Signals

Name	I/O [1]	Source	Reset Domain
DPLL1_RSTPWRON	I	PRCM	Resets the DPLL1 module
DPLL2_RSTPWRON	I	PRCM	Resets the DPLL2 module
DPLL3_RSTPWRON	I	PRCM	Resets the DPLL3 module
DPLL4_RSTPWRON	I	PRCM	Resets the DPLL4 module
DPLL5_RSTPWRON	I	PRCM	Resets the DPLL5 module

(1) I = Input; O = Output

They are asserted for any type of global cold reset.

3.5.1.5.13 EFUSE Power Domain

The EFUSE power domain has one reset input signal (see Table 3-21).

Table 3-21. EFUSE Power Domain Reset Signal

Name	I/O [1]	Source	Reset Domain
EFUSE_RSTPWRON	I	PRCM	Resets the eFuse controller

(1) I = Input; O = Output

This signal is asserted for any type of global cold reset and when the device wakes up from off mode.

3.5.1.5.14 BANDGAP Logic

The BANDGAP logic has one reset input signal (see Table 3-22).

Table 3-22. BANDGAP Logic Reset Signal

Name	I/O [1]	Source	Reset Domain
BANDGAP_RSTPWRON	I	PRCM	Resets the BANDGAP logic

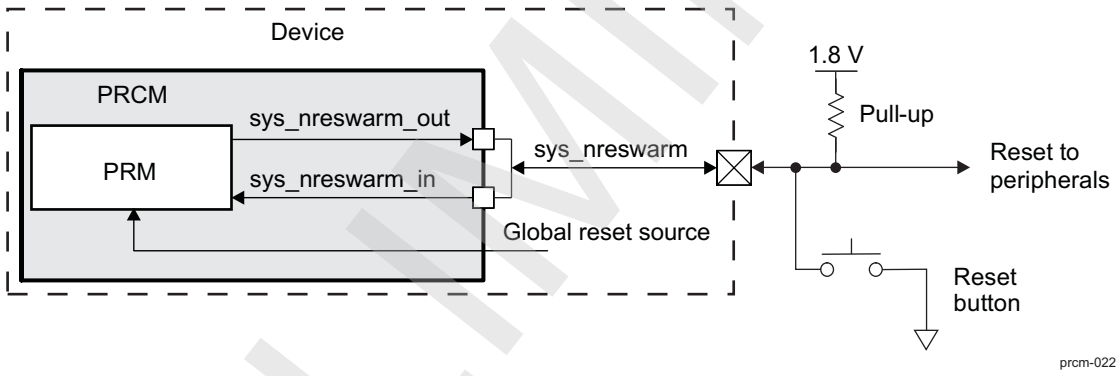
(1) I = Input; O = Output

This signal is asserted for any type of global cold reset and when the device wakes up from off mode.

3.5.1.5.15 External Warm Reset Assertion

Figure 3-23 shows the external warm reset interface.

Figure 3-23. External Warm Reset Interface



Any global reset source (internal or external) causes sys_nreswarm_out to be driven and maintained at the boundary of the device for at least the amount of time configured in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field. This ensures that the device and its related peripherals are reset together.

NOTE: Because the system warm-reset output is implemented on a bidirectional pad, any input pulse on sys_nreswarm causes a global warm reset.

3.5.1.6 Reset Logging

A reset of the device is logged in two ways. First, dedicated registers in the PRCM module (the RM_RSTST_power domain> and PRM_RSTST registers) log the reset source. Second, the SCM logs the device reset activity in dedicated registers.

3.5.1.6.1 PRCM Reset Logging Mechanism

The reset status registers (RM_RSTST_power domain> and PRM_RSTST) are reset asynchronously on assertion of a global cold reset. However, a reset status bit is always logged when the reset is released to the domain.

For this reason, after the assertion of a global cold reset, the reset status register is cleared to 0. When the domain reset is released, the register bit to log the global cold reset (the RM_RSTST_<power domain> [0] GLOBALCOLD_RST bit) is updated to 1. For the same reason, the reset status register of domains released from reset by software is updated only when software releases the domain reset.

The assertion of a global cold reset prevents logging any other source of reset until after the release of the domain reset. This is valid in the following situations:

- A source of reset other than global cold reset is asserted before, during, or after the active period of a global cold source of reset and before the release of the domain reset signal.
- A source of reset other than global cold reset was asserted and then released, but a global cold reset source was asserted before the release of the domain reset signal.

3.5.1.6.2 SCM Reset Logging

The PRM exports reset the activity status signals to the SCM. The SCM uses these signals to log a reset status in the SCM.CONTROL_SEC_STATUS register. The reset activity status signal is asserted high when any source of reset to the power domain is active.

It also provides reset status for the following global reset signals:

- Global cold reset
- Global warm reset

There is one reset activity status signal for each of the following power domains:

- CAM
- CORE
- DSS
- EMU
- SGX
- IVA2
- MPU
- NEON
- PER
- USBHOST

These signals are asserted high on assertion of any source of reset on the domain and logged. For information about the SCM, see Chapter 13, *System Control Module*.

3.5.1.7 Reset Management Overview

Reset management in the device is a 2-layered structure composed of multiple instances of the reset manager. In the first layer, a top-level reset manager, called the device reset manager, handles all sources of global reset (cold and warm). It provides reset managers for the second layer, called local reset managers, and the global reset and global power-on reset signals.

Each power domain has a minimum of one local reset manager. The local reset manager also receives resets, such as the software reset and domain power transition reset, from the local reset source for the power domain.

Figure 3-24 through Figure 3-27 provide an overview of reset management in the device. They do not provide reset sequencing between the reset managers.

NOTE: The power domain must be ready (the domain clocks must be active) before its reset is released.

Figure 3-24. Device Reset Manager Overview

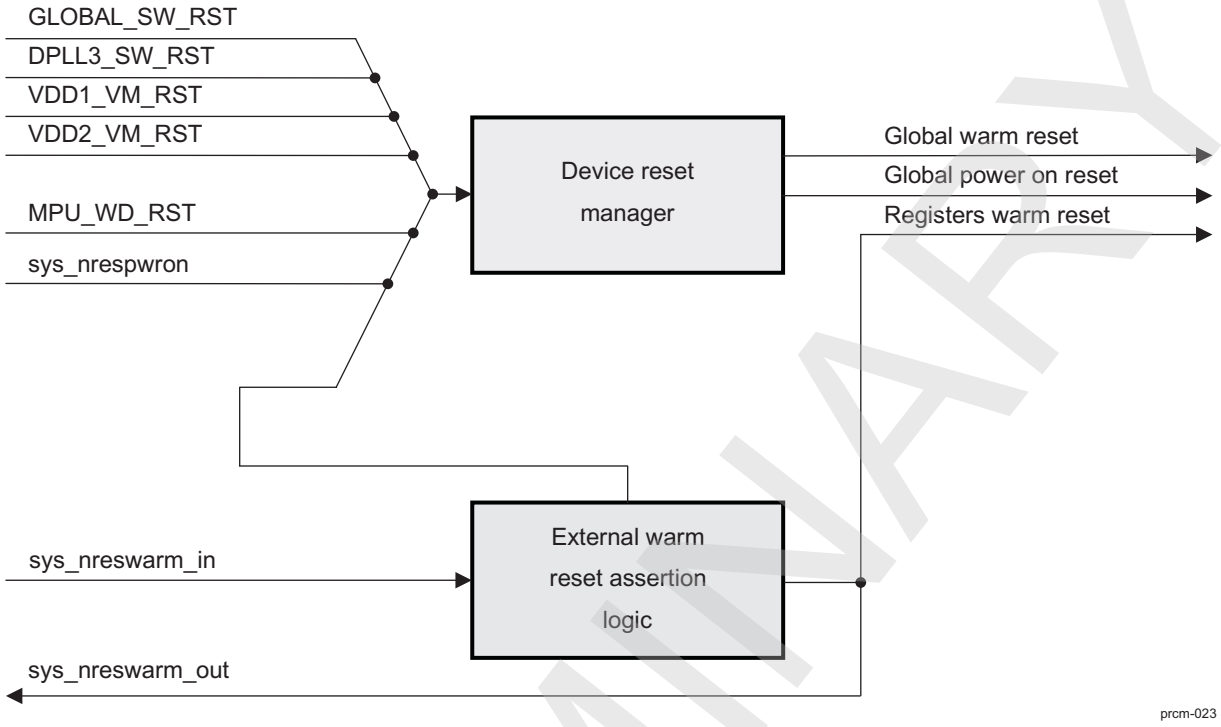


Figure 3-25. Power Domain Reset Management: Part 1

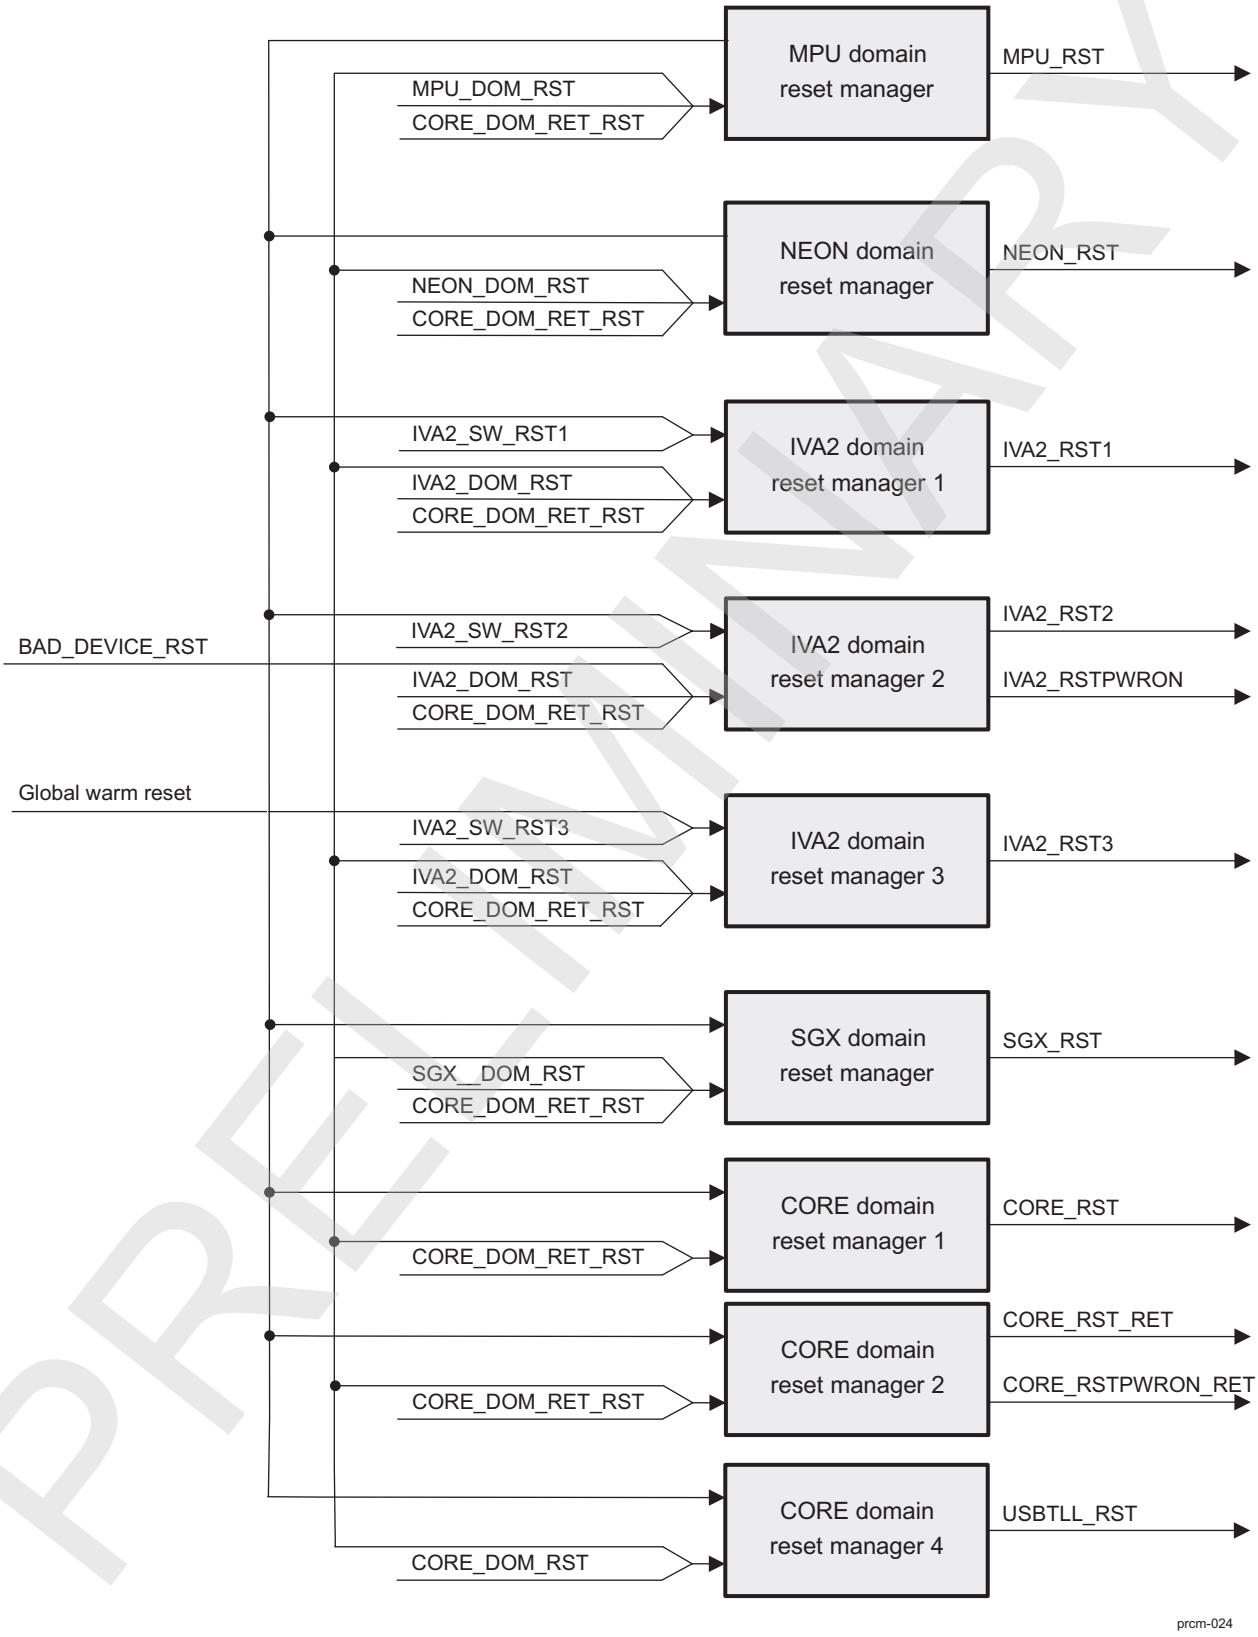

Figure 3-26. Power Domain Reset Management: Part 2

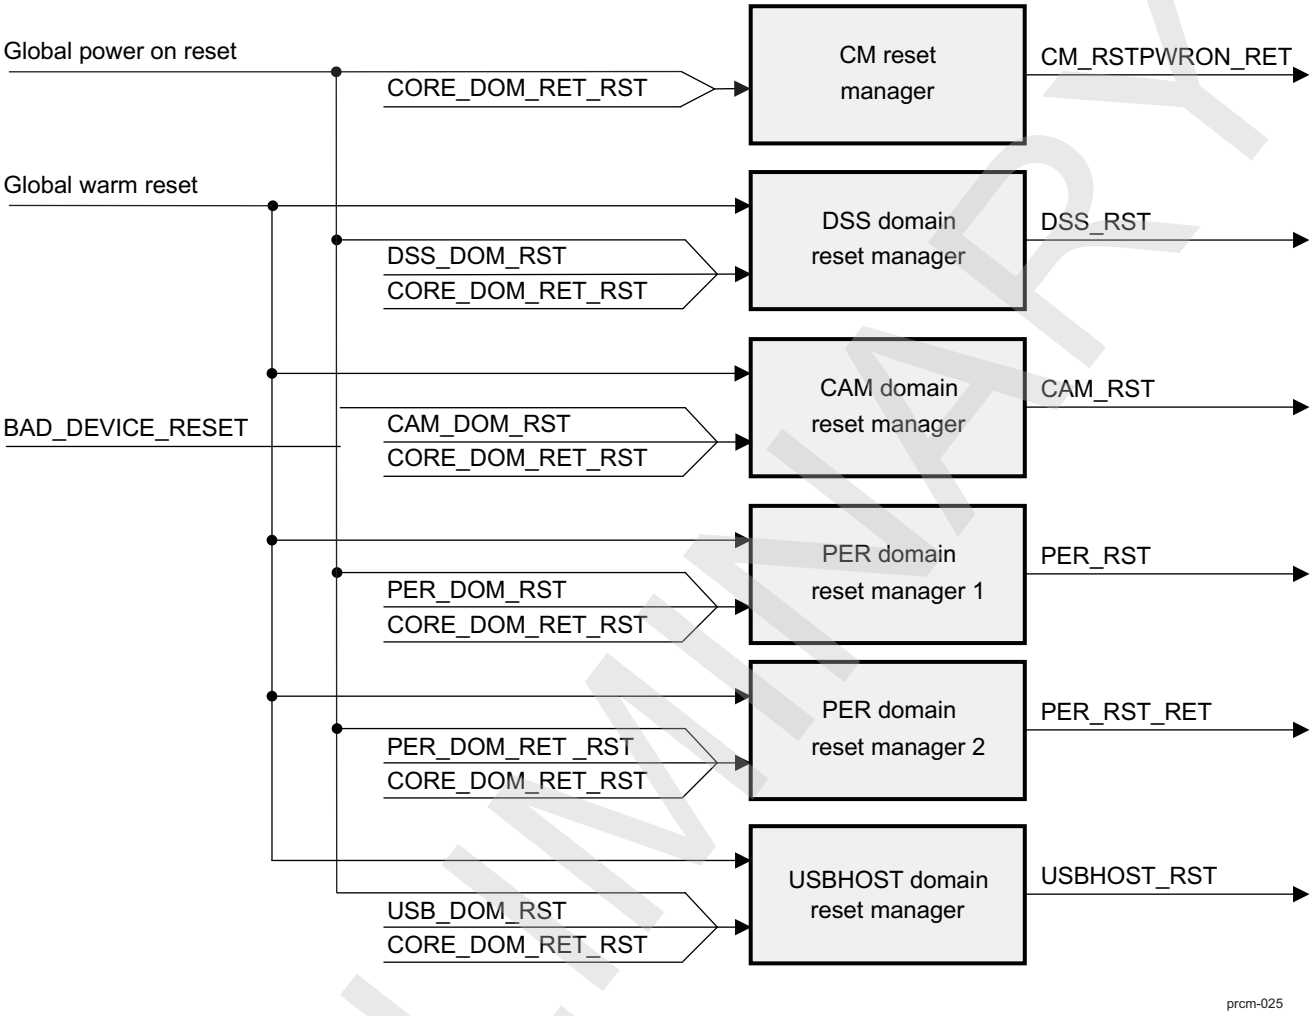

Figure 3-27. Power Domain Reset Management: Part 3

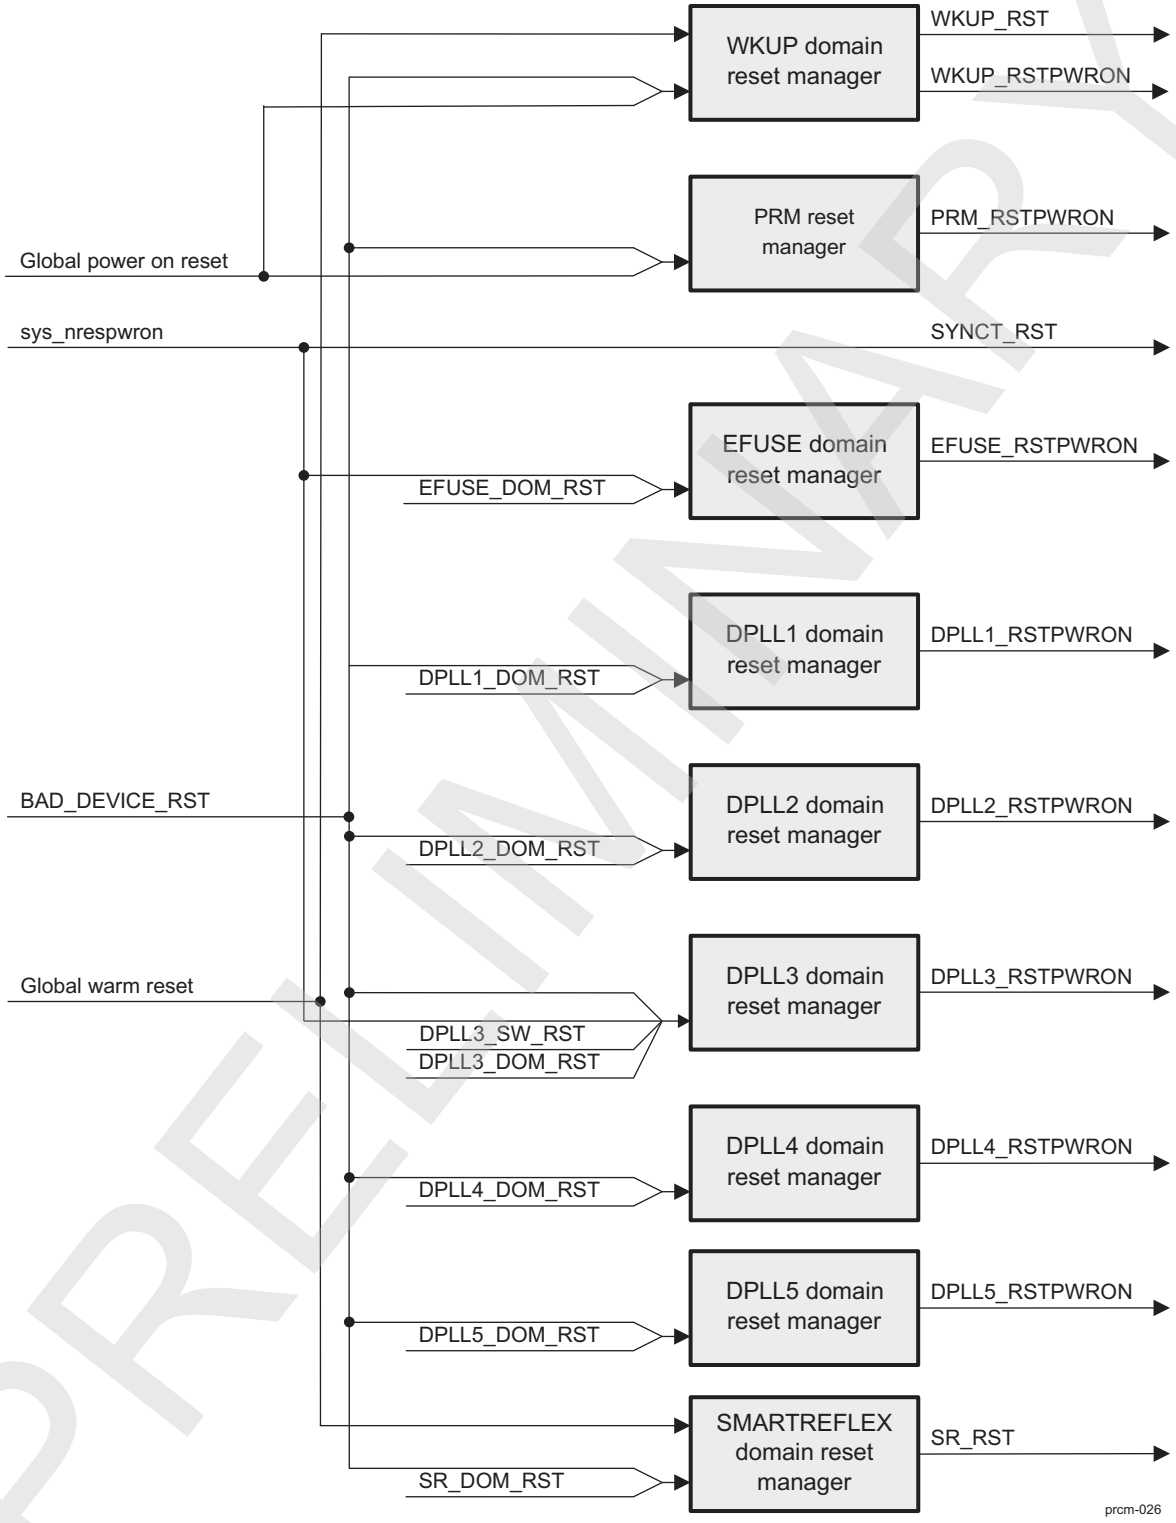

3.5.1.8 Reset Summary

Table 3-23 and Table 3-24 summarize the sources of global and local resets and their actions on the reset signals.

Table 3-23. Global Reset Summary[1]

Domain Resets		Reset Sources

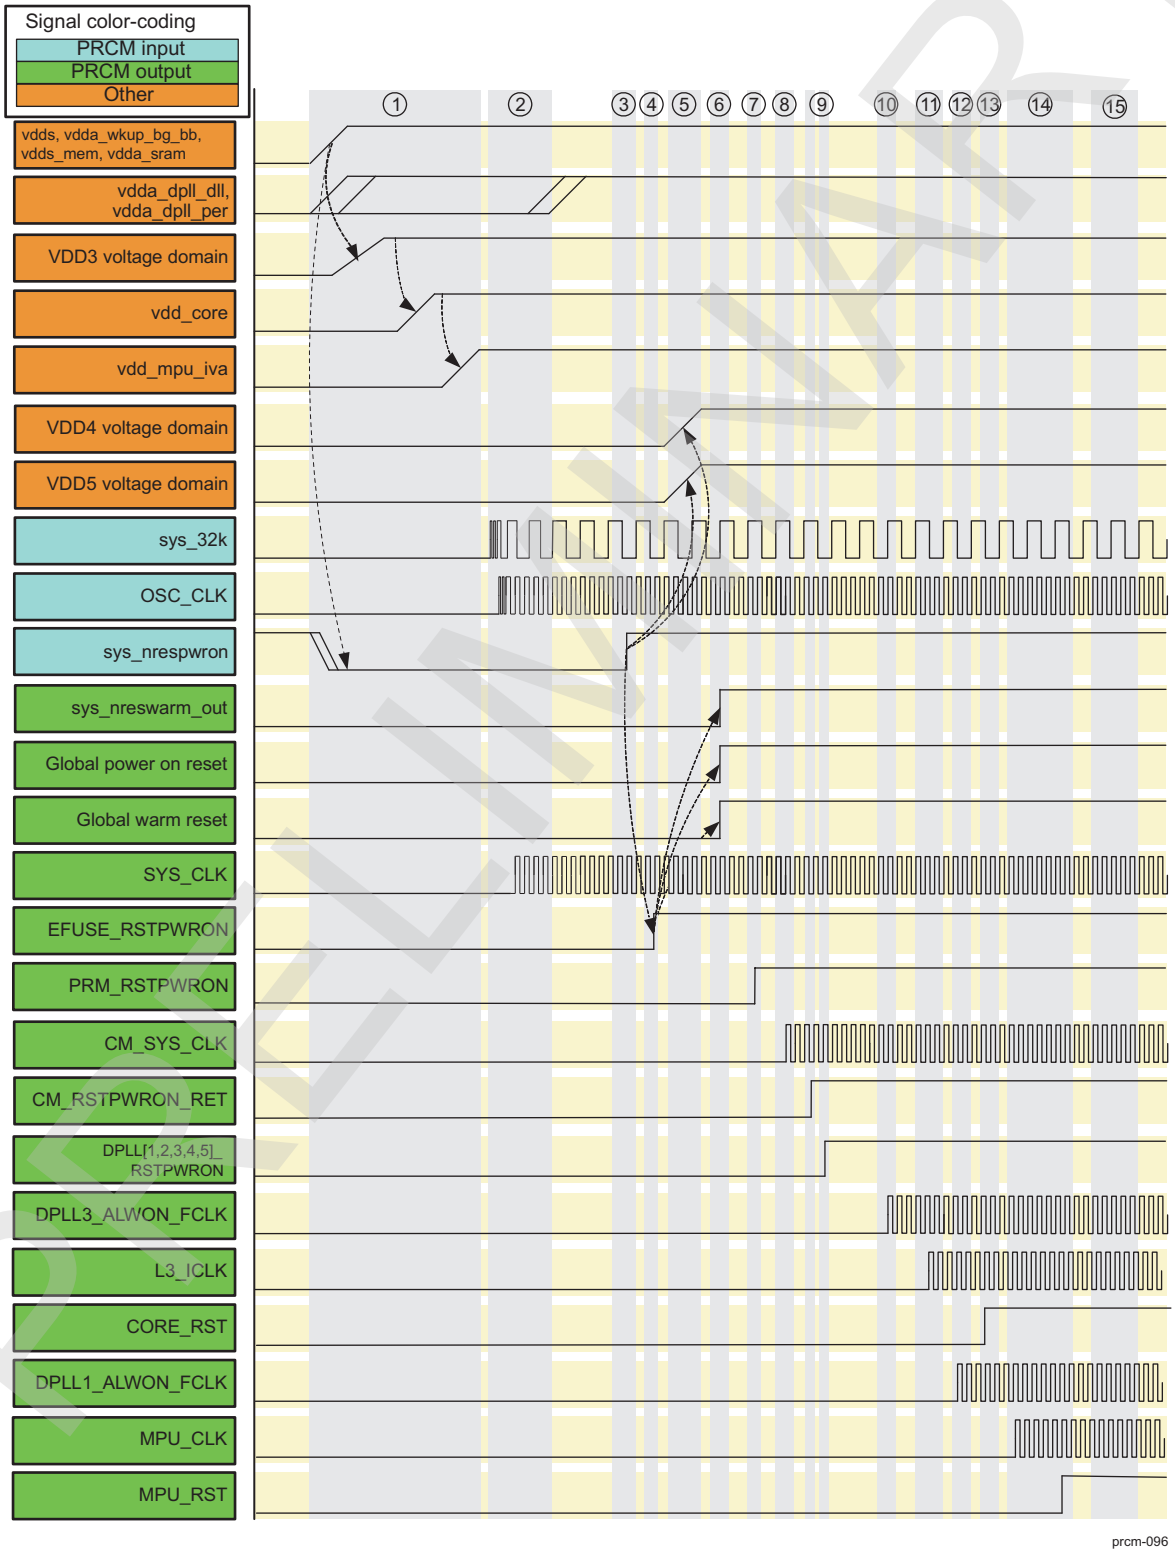
3.5.1.9 Reset Sequences

3.5.1.9.1 Power-Up Sequence

Figure 3-28 shows the power-up sequence.

Figure 3-28. Power-Up Sequence



The power-up sequence shown in Figure 3-28 is:

1. Voltages ramp up and global power-on reset is asserted by the external power IC:
   - vdds, vdds_mem, vdda_wkup_bg_bb, vdda_sram voltage rails are ramped up.
   - sys_nrespwron is asserted (set to low).
   - vdda_dpll_dll and vdda_dpll_per voltage rails are ramped up before release of sys_nrespwron (transition to high).
   - The VDD3 voltage domain LDO (WKUP power domain) tracks vdda_wkup voltage rail and automatically ramps up.
   - After VDD3 voltage domain stabilization, the power IC ramps up VDD2 voltage domain.
   - After VDD2 voltage domain stabalization, the power IC ramps up VDD1 voltage domain.
2. Source clock stabilizes:
   - The 32-kHz input clock and the system clock oscillator stabilize.
   - The device reset manager holds the entire device under reset.
   - The system clock (SYS_CLK) is on.
3. The global power-on reset sys_nrespwron released (to high) when vdda_dpll_dll and vdda_dpll_per voltage rails are stabilized.
4. The eFuse farm reset is released.
5. Internal memory LDOs ramp up:
   - Processor memory LDO (VDD4 voltage domain) is ramped up.
   - CORE memory LDO (VDD5 voltage domain) is ramped up.
   - The PRCM module waits for internal memory LDO stabilization.
6. Global resets are released. Global power-on reset and global warm reset are extended (remain asserted) on release of the external power-on reset until the following conditions are met:
   - Voltages are stable in the processor power domains, CORE power domain, and WKUP power domain.
   - System clock is stable.
   - Internal memory LDO is stable.
   - Device reset manager counter overflows (set up by the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).
   - Hardware conditions, such as eFuse farm ready, are set.
7. The PRM_RSTPWRON reset is released.
8. The CM_SYS_CLK clock starts running (gating logic is enabled).
9. The CM_RSTPWRON_RET reset is released.
10. The reset of the DPLLs is released.
11. The DPLL3_ALWON_FCLK clock starts to run (gating logic is enabled).
12. The L3_ICLK clock starts to run.
13. The DPLL1_ALWON_FCLK clock starts to run (logic controlling the clock-gating conditions element is clocked and the clock is requested).
14. The CORE_RST reset is released.
15. The MPU_CLK clock starts to run.
16. The MPU boots.

NOTE:

- The IVA2 power domain is held under reset after power up by assertion of the software source of reset.
- Power domains such as DSS, CAM, SGX, and NEON are held under reset after power up until the MPU software enables the power domain interface clocks.

3.5.1.9.2 Global Warm Reset Sequence

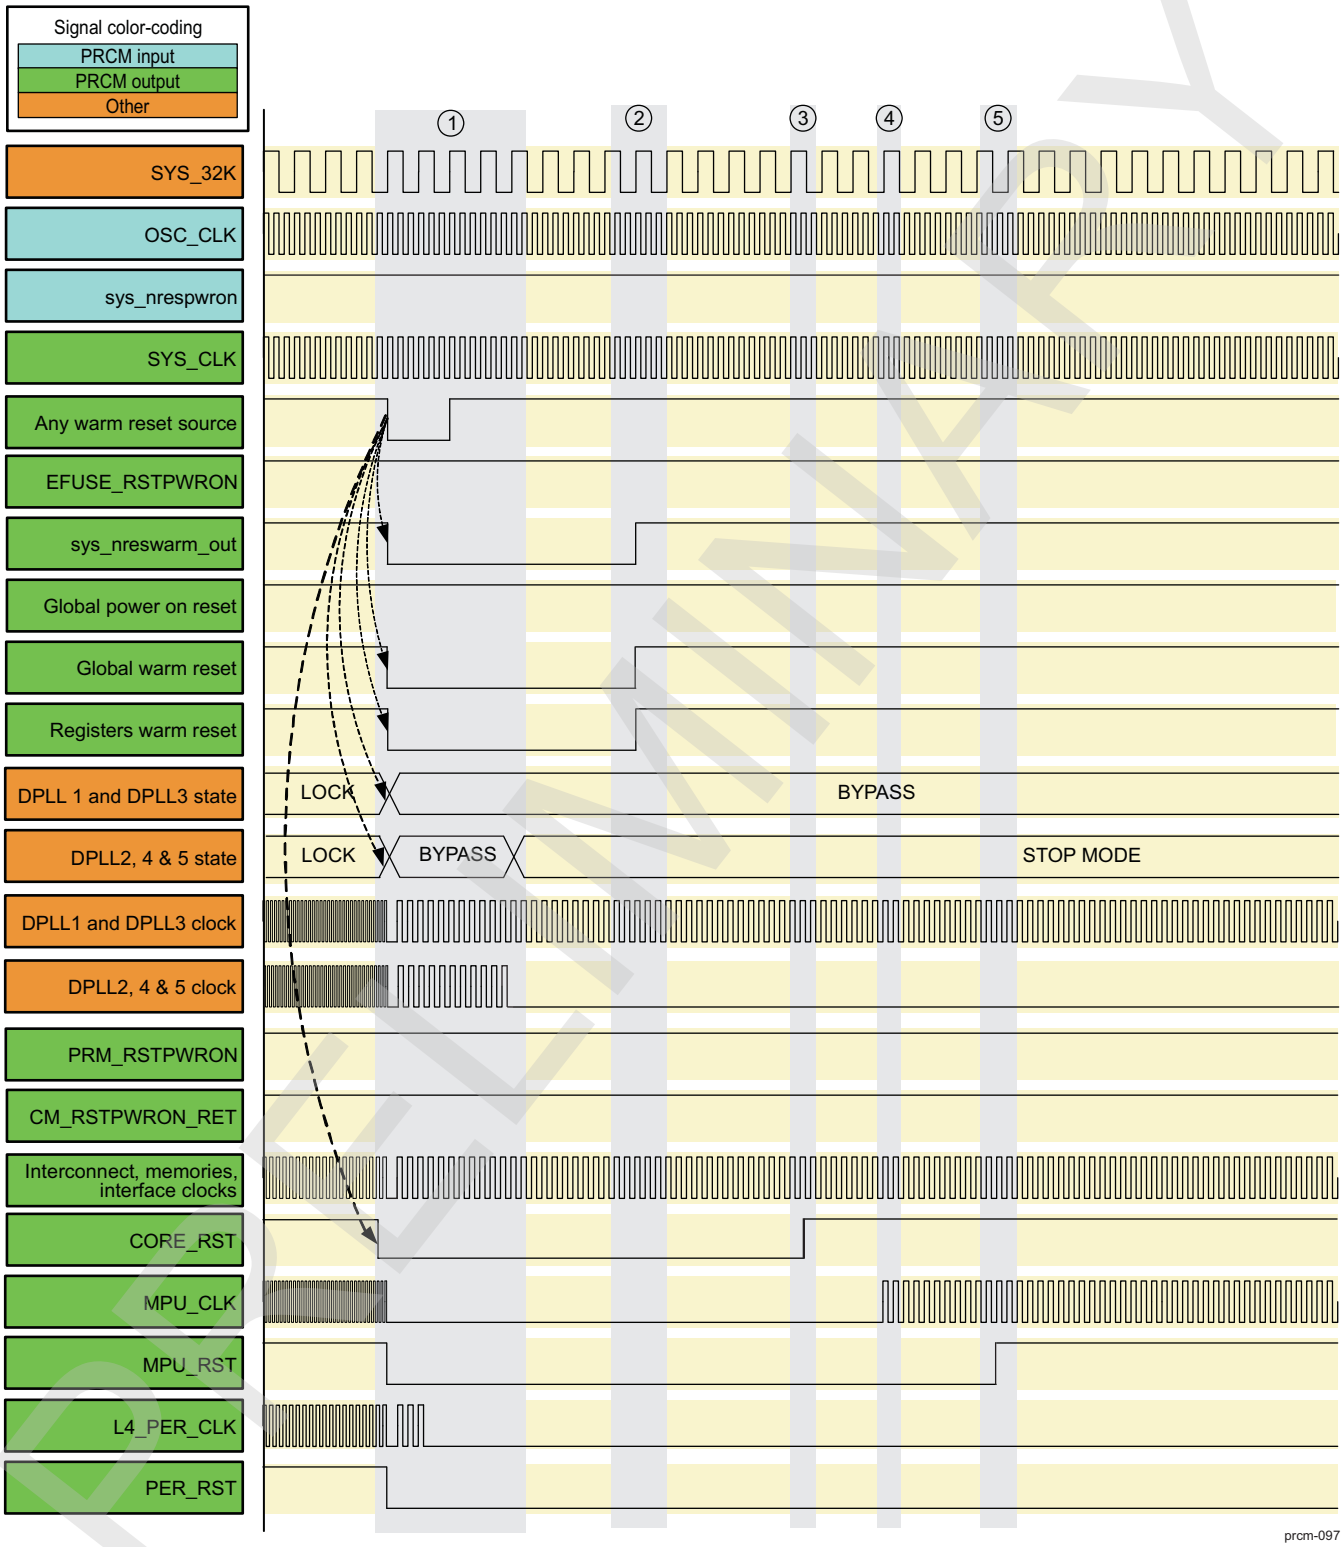
This section describes the global reset sequence.

The assumptions are:

- vdds, vdds_mem, vdda_dpll_pll, vdda_dpll_per, vdda_wkup_bg_bb and vdda_sram power rails are regulated at 1.8 V.
- The VDD2 voltage domain (vdd_core power rail) is regulated at 1.0 V.
- The VDD1 voltage domain (vdd_mpu_iva power rail) is regulated at 1.2 V.
- The VDD3, VDD4, and VDD5 voltage domains are regulated at 1.2 V.
- The system is running:
  - Resets are released.
  - CORE DPLL and processor DPLL are locked.

Figure 3-29 shows the global warm reset sequence.

Figure 3-29. Warm Reset Sequence



The steps of a global warm reset sequence are as follows:

1. On assertion of the warm reset source:
   - The device reset manager resets part of the device by asserting the global warm reset.
   - The external warm reset (sys_nreswarm_out) is asserted.

- All the power domain warm resets are asserted.
- DPLL1 and DPLL3 transit to bypass mode. DPLL2, DPLL4, and DPLL5 transit to stop mode. The system clock, SYS_CLK, continues running at system clock frequency.
- The registers sensitive to a warm reset are synchronously reset (PRM and CM register sets).
- The CM cuts all the clocks not requested, according to the register reset value settings.

2. The global warm reset is released and extended after release of the warm reset source until the following conditions are met:
   - Device reset manager counter overflows (set up by the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).
   - Voltage domains (VDD1, VDD2, VDD4 and VDD5) are stable.

   NOTE: Voltage stabilization is an additional condition if voltage scaling was performed before the assertion of the warm reset.

3. The CORE domain is released from reset (warm sensitive modules in CORE power domain).
4. The MPU_CLK clock is running.
5. The MPU power domain is released from reset. The MPU boots.

NOTE:

- The IVA2 power domain is held under reset after global warm reset by assertion of the software source of the reset.
- Power domains such as PER, DSS, CAM, SGX, and NEON are held under reset after global warm reset until the MPU software enables their interface clock.

3.5.1.9.3 IVA2.2 Subsystem Power-Up Sequence

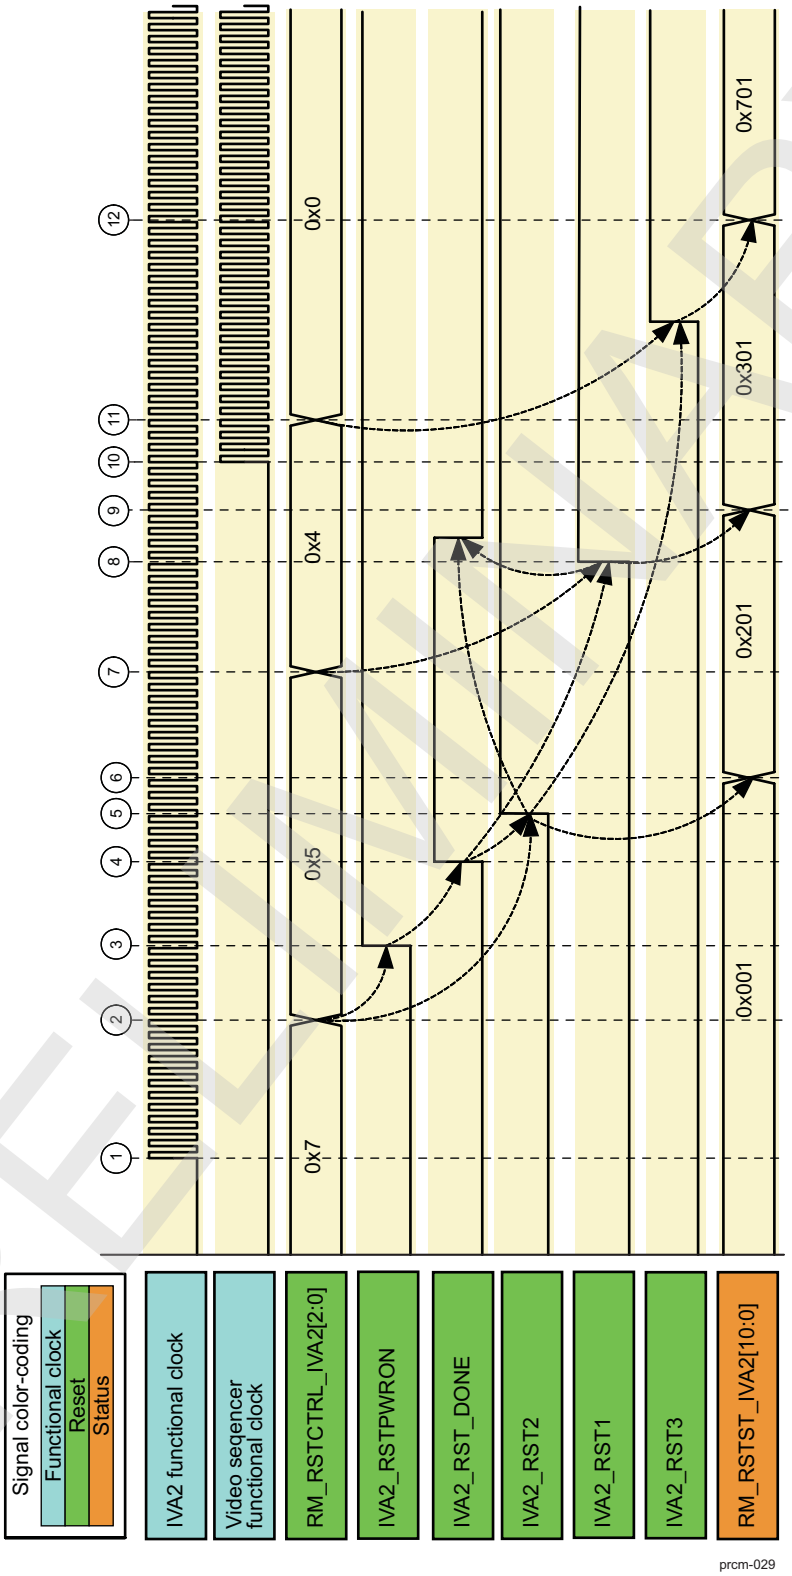
This section describes the power-up reset sequence and timing relationships of the IVA2.2 subsystem.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released except for the software sources of reset.

Figure 3-30 shows the IVA2.2 power-up sequence.

Figure 3-30. IVA2.2 Subsystem Power-Up Reset Sequence



The sequence is:

1. Software enables the IVA2.2 subsystem clock.

2. Software clears the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit. The PRM module releases the IVA2_RSTPWRON reset signal when reset manager 2 in the IVA2 power domain times out.
3. On release of IVA2_RSTPWRON, the IVA2.2 subsystem performs an initialization sequence.
4. The IVA2.2 subsystem asserts the IVA2_RST_DONE signal when initialization completes.
5. The PRM module releases the IVA2_RST2 reset signal.
6. The PRCM.RM_RSTST_IVA2[9] IVA2_SW_RST2 status bit is updated accordingly on release of the IVA2_RST2 reset signal. The MPU software can now program the MMU or download the DSP code.
7. Software clears the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit. The PRM module waits for reset manager 1 in the IVA2 power domain to time out.
8. The PRM module releases the IVA2_RST1 reset signal. The DSP boots.
9. The PRCM.RM_RSTST_IVA2[8] IVA2_SW_RST1 status bit is updated accordingly on release of the IVA2_RST1 reset signal.
10. DSP software enables the video sequencer (SEQ) clock.
11. DSP software clears the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit. The PRM waits for reset manager 3 in the IVA2 power domain to time out.
12. After reset manager 3 times out, the PRM can release the IVA2_RST3 reset signal. The SEQ boots.
13. The PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 bit is updated accordingly on release of the IVA2_RST3 reset signal.

3.5.1.9.4 IVA2 Software Reset Sequence

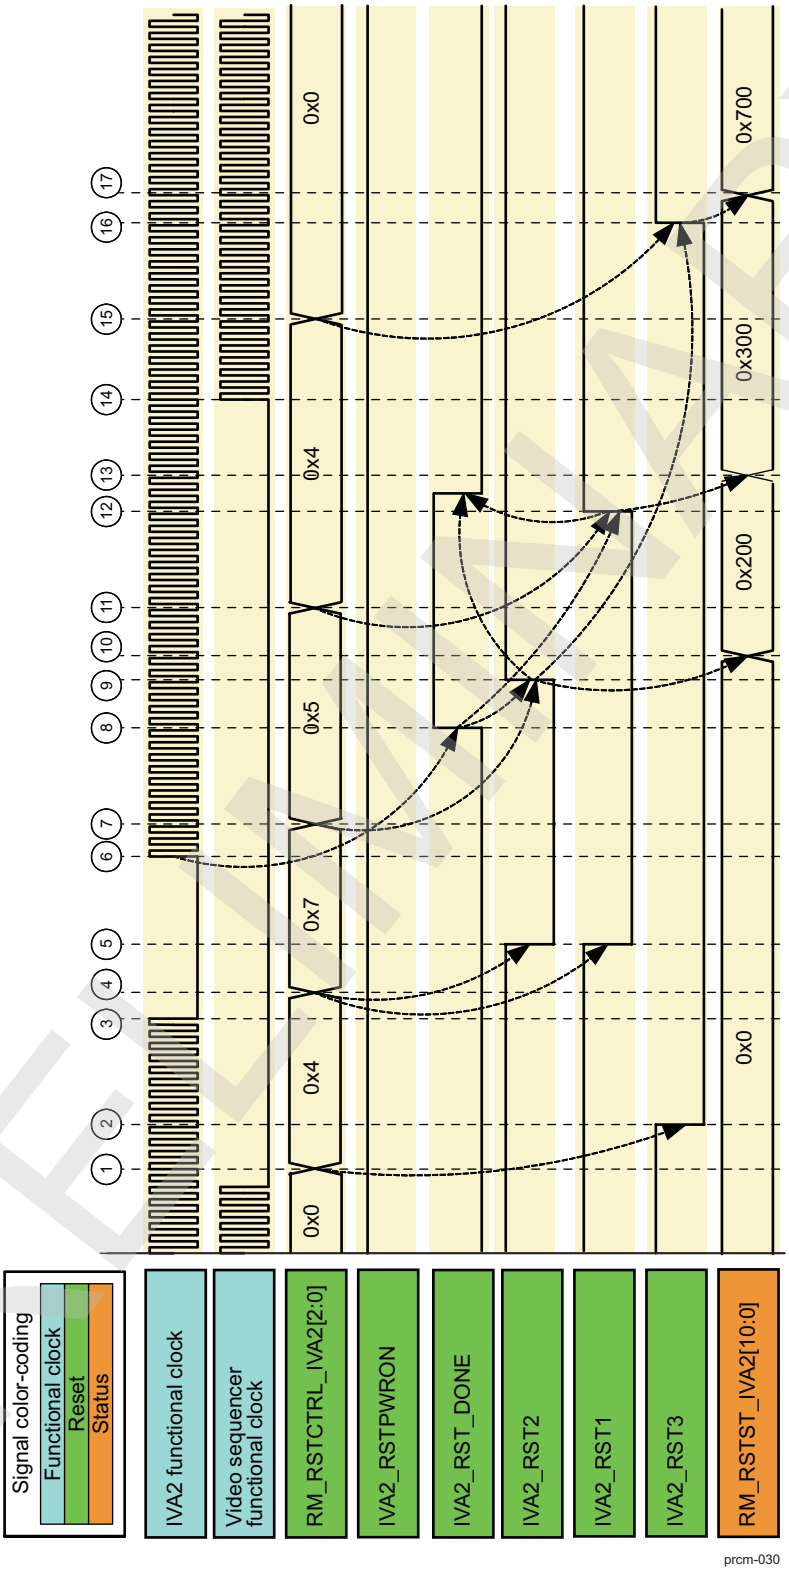
This section describes the software reset sequence and timing relationships of the IVA2.2 subsystem.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released.
- The software ensures that the IVA2.2 subsystem software sources of reset are not asserted while the IVA2 power domain clocks are running.
- The software clears the previous reset status.

Figure 3-31 shows the IVA2 software reset sequence.

Figure 3-31. IVA2 Software Reset Sequence



The sequence is:

1. DSP software puts the SEQ in idle, and can safely assert the IVA2 power domain software reset.
2. The PRM module asserts the IVA2_RST3 reset asynchronously.

3. The DSP goes to idle, and the CM gates the IVA_CLK clock.
4. MPU software asserts the IVA2.2 subsystem software reset.
5. The PRM asserts all remaining IVA2 power domain warm resets asynchronously.
6. MPU software enables the IVA2 power domain clock. A partial initialization sequence is performed.
7. MPU software clears the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit.
8. The IVA2.2 subsystem asserts the IVA2_RST_DONE signal when initialization completes.
9. The PRM module releases the IVA2_RST2 reset signal when reset manager 2 in the IVA2 power domain times out.
10. The PRCM.RM_RSTST_IVA2[9] IVA2_SW_RST2 status bit is updated accordingly on release of the IVA2_RST2 reset signal. MPU software now programs the MMU or downloads the DSP code.
11. Software clears the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit. The PRM module waits for reset manager 1 in the IVA2 power domain to time out.
12. After reset manager 1 times out, the PRM module releases the IVA2_RST1 reset signal. The DSP boots.
13. The PRCM.RM_RSTST_IVA2[8] IVA2_SW_RST1 status bit is updated accordingly on release of the IVA2_RST1 reset signal.
14. DSP software enables the SEQ clock.
15. DSP software clears the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit. The PRM module waits for reset manager 3 in the IVA2 power domain to time out.
16. The PRM module releases the IVA2_RST3 reset signal. The SEQ boots.
17. The PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 status bit is updated accordingly on release of the IVA2_RST3 reset signal.

3.5.1.9.5 IVA2 Global Warm Reset Sequence

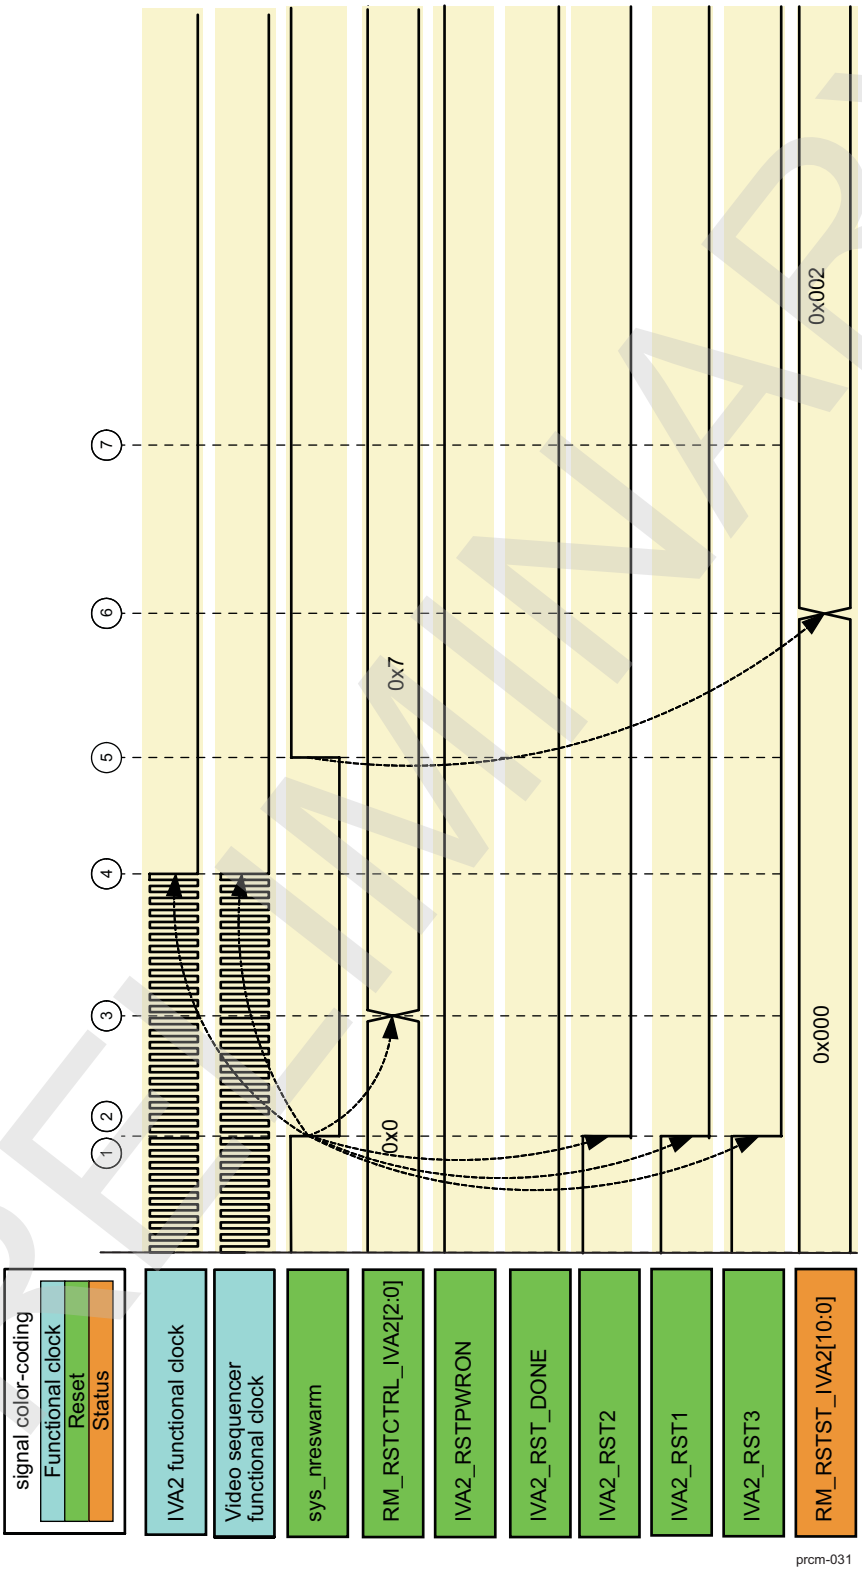
This section describes the reset sequence of the IVA2.2 subsystem and timing relationships on a global warm reset.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2.2 subsystem are released.
- Software clears the previous reset status.

Figure 3-32 shows the IVA2 global warm reset sequence.

Figure 3-32. IVA2 Global Warm Reset Sequence



The sequence is:

1. A global warm reset source is asserted (see sys_nreswarm in Figure 3-32).

2. The PRM asserts asynchronously all IVA2 power domain warm reset signals (and all other warm reset signals).
3. The PRCM.RM_RSTCTRL_IVA2 register is reset to its default value. As a result, the IVA2 power domain warm reset signals stay asserted on release of the global warm source of reset.
4. DPLL2 is held under its reset configuration; the IVA2 power domain clocks are stopped.
5. The sys_nreswarm global warm source of reset is deasserted.
6. The PRCM.RM_RSTST_IVA2 status register is updated accordingly when the device reset manager times out.
7. The MPU boots and the MPU software sequence, shown in Section 3.5.1.9.4, from point 6, starts.

3.5.1.9.6 IVA2 Power Domain Wake-Up Cold Reset Sequence

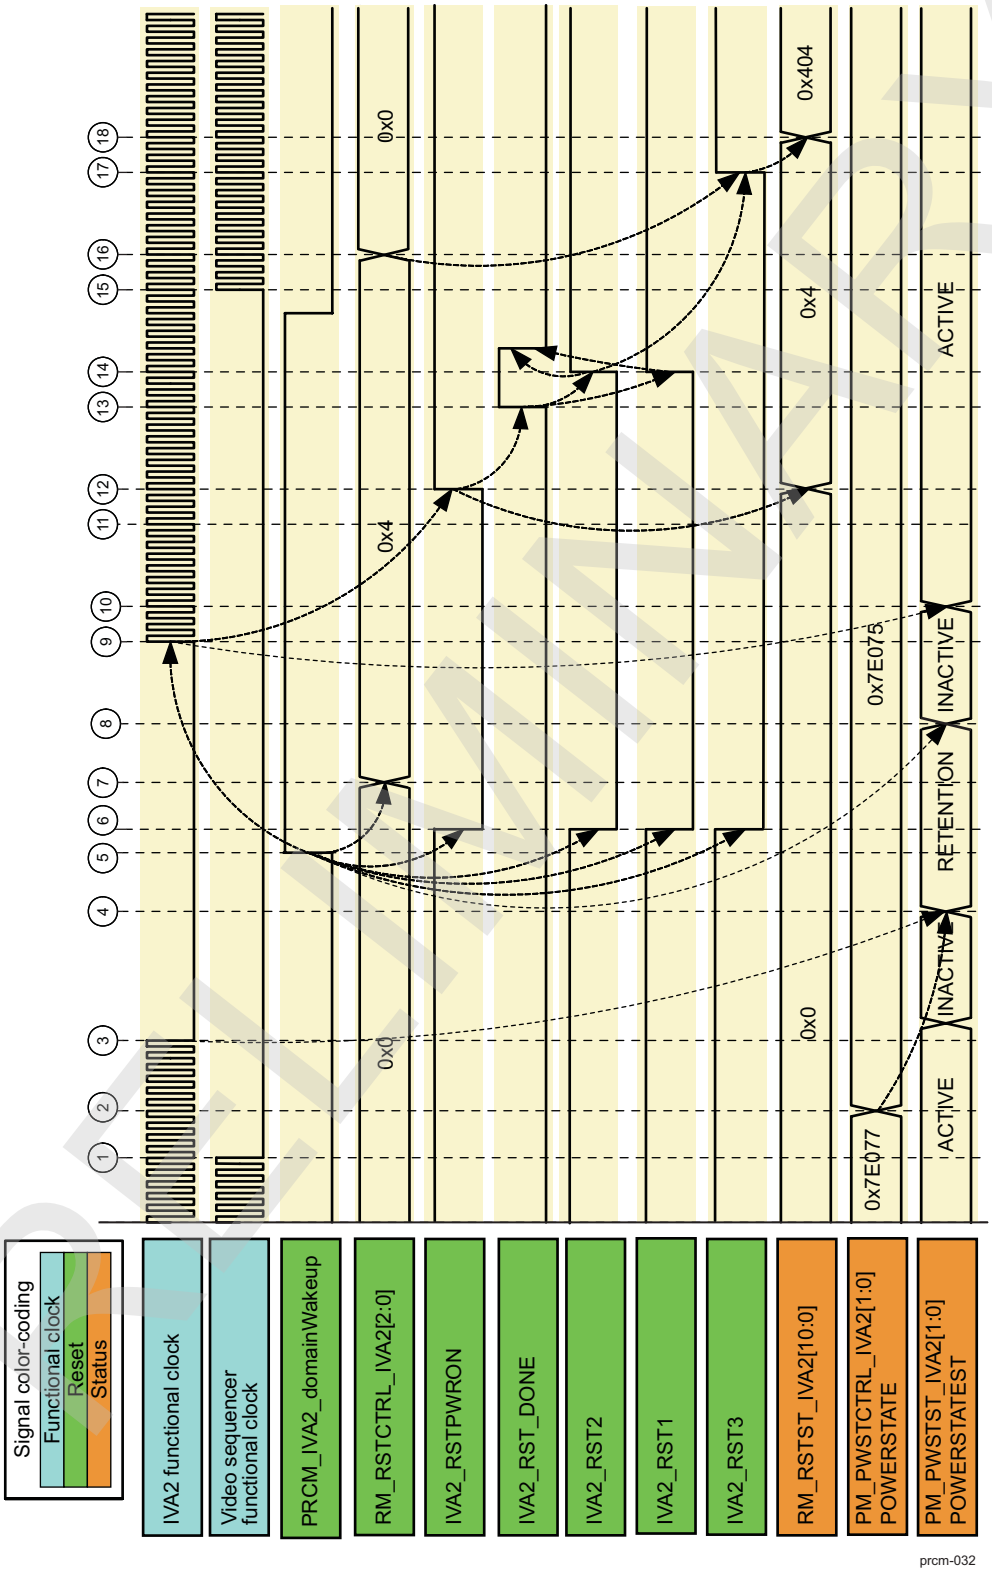
This section describes the cold reset sequence of the IVA2.2 subsystem when the IVA2 power domain transitions from retention to on power state.

The assumptions are:

- The MPU is running.
- All sources of reset to the IVA2 are released.
- The software ensures that the IVA2 power domain software sources of reset are not asserted while the IVA2 clocks are running.
- The software clears the previous reset status.

Figure 3-33 shows the IVA2 power domain wake-up cold reset sequence.

Figure 3-33. IVA2 Power Domain Power Transition Reset Sequence



The sequence is:

1. DSP software puts the SEQ in inactive state.

2. MPU software programs the IVA2 power domain to go to retention power state during the next sleep transition.
3. The DSP goes to idle mode, and the CM gates the IVA2 clock. The IVA2 power domain enters inactive power state.
4. The IVA2 power domain enters retention power state.
5. The IVA2 power domain is awakened.
6. The PRM asserts the cold reset IVA_RSTPWRON and all IVA2 warm resets asynchronously.
7. The PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit is automatically reset to its reset value.
8. The IVA2 power domain is inactive.
9. IVA2 clocks are automatically reenabled. The IVA2 power domain enters active power state.
10. The PRM releases the IVA2_RSTPWRON reset signal when reset manager 2 in the IVA2 power domain times out.
11. On release of IVA2_RSTPWRON, the IVA2 performs an initialization sequence.
12. The PRCM.RM_RSTST_IVA2 register is updated accordingly on release of the IVA2_RSTPWRON reset signal.
13. The IVA2.2 subsystem asserts the IVA2_RSTDONE signal when initialization completes.
14. The PRM module releases the IVA2_RST1 and IVA2_RST2 reset signals. The DSP boots in autonomous mode.
15. DSP software enables the SEQ clock.
16. DSP software clears the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit. The PRM module waits for reset manager 3 in the IVA2 power domain to time out.
17. After reset manager 3 times out, the PRM module releases the IVA2_RST3 reset signal. The SEQ boots.
18. The PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 bit is updated accordingly on release of the IVA2_RST3 reset signal.

There are two alternate sequences:

- The DSP is held under reset when exiting retention power state. This is done when the MPU software writes 1 to the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit. In this case, the MPU software must clear this bit to 0 to reboot the DSP.
- The DSP and MMU are held under reset when exiting retention power state (the MPU software writes 1 to the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 and PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bits). In this case, the MPU software must first clear the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit to allow the release of the reset IVA_RSTPWRON and subsequently (after initialization) the release of IVA2_RST2. Only after the MPU software reprograms the MMU or downloads the DSP code can it clear the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit field to boot the DSP.

NOTE:

- Although the IVA2.2 WUGEN module and DPLL2 are part of the IVA2.2 subsystem, they are also part of the CORE power domain and the DPLL2 power domain, respectively. They are reset independently from the IVA2 power domain.
- The IVA2_RSTPWRON reset is released by software by programming the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit. Setting the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit does not assert IVA2_RSTPWRON.
- IVA2_RST3 is asserted when the IVA2 power domain transitions from off or retention state to on state. The corresponding bit in the PRCM.RM_RSTCTRL_IVA2 register is automatically set to 1 during this transition.
- The release of the IVA2_RST3 reset is stalled as long as the IVA2_RST2 reset is not released.
- The release of the IVA2_RST2 and IVA2_RST1 resets causes IVA2 to deassert the IVA2_RSTDONE signal.

3.5.2 PRCM Power Manager Functional Description

3.5.2.1 Overview

3.5.2.1.1 Introduction

To efficiently manage leakage and reduce dynamic power consumption, the device supports several power-management techniques:

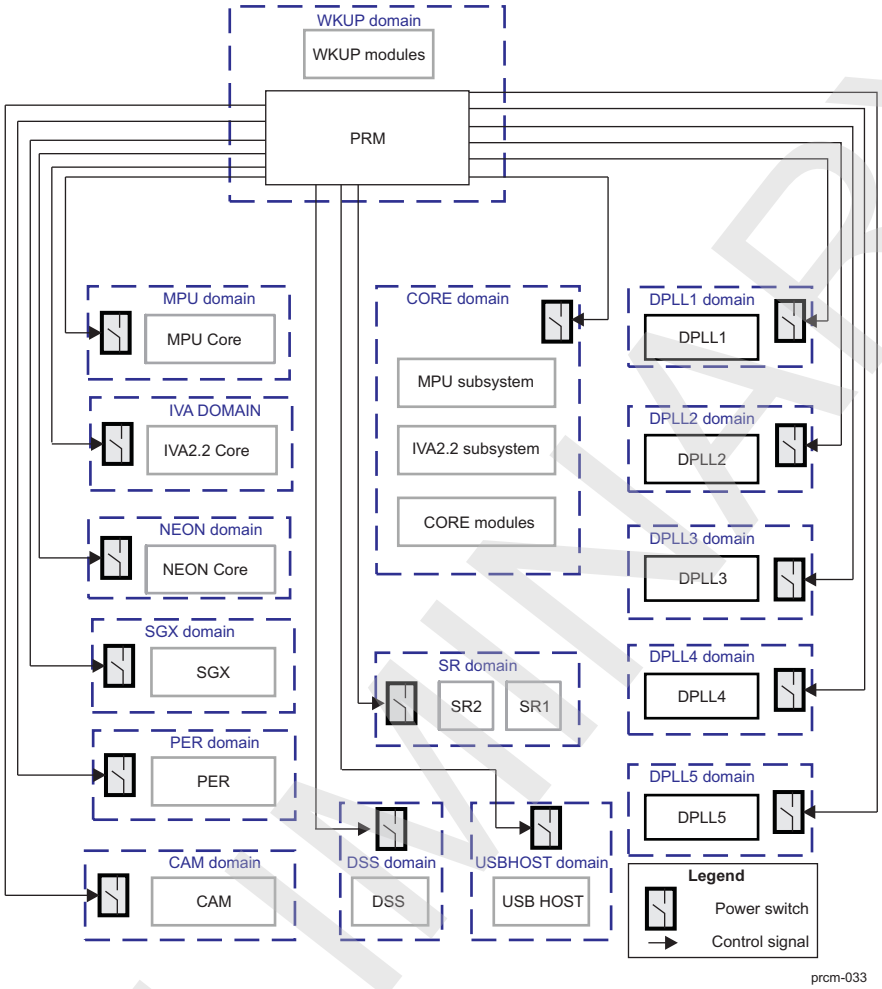
- Dynamic clock-gating conditions
- DVFS
- DPS
- SLM

These power-management techniques require software control and specific hardware features. The hardware features are fully controlled by the PRM part of the PRCM module. These features are:

- Device partitioning into 18 power domains
- Device partitioning into several voltage domains communicating through level shifters
- Logic power-switch control
- RFF control
- Memory power-switch control
- Embedded LDOs (SRAMs, wakeup, emulation) control
- I/O off-mode control
- Level shifter control
- External power IC control

Figure 3-34 is an overview of PRM power management in the device.

Figure 3-34. Power Control Overview



3.5.2.1.2 Device Partitioning

To substantially reduce leakage in sleep modes (SLM strategy) and to optimize active power-consumption savings (DPS strategy), the device is segmented into 18 power domains:

- MPU: Application processor
- NEON: Multimedia coprocessor
- IVA2: DSP
- SGX: Graphics engine
- CORE: Interconnect, memory controllers, peripherals, and clock management
- DSS: Display subsystem
- CAM: Camera controller
- PER: Low-power use case peripherals
- WKUP: Wakeup (always active)
- USBHOST: USB HOST power domain
- EMU: Emulation
- SMARTREFLEX: SmartReflex modules
- EFUSE: eFuse farm
- DPLL1: MPU DPLL
- DPLL2: IVA2.2 DPLL
- DPLL3: CORE DPLL

- DPLL4: Peripherals DPLL
- DPLL5: Peripherals DPLL2

Each power domain receives power through an independent switch controlled by the PRM module. In this way, depending on the application scenario, unused power domains can be switched off or put in retention state while others remain active.

Table 3-25 lists the device modules in relation to the power domains.

Table 3-25. Power Domain Modules

Power Domain	Modules
MPU	MPU core
	ICECrusher CS
	MPU async bridge (master)
NEON	NEON coprocessor
IVA2	IVA2.2 DSP
	IVA2 async bridge 1 (master)
	IVA2 async bridge 2 (slave)
	Video sequencer (SEQ)
SGX	SGX subsystem
CORE	GPMC
	USB TLL
	GPTIMER[10, 11]
	HDQ/1-Wire
	HS USB
	I2C[1, 2, 3]
	ICR
	IVA2.2 async bridge 1 (slave)
	IVA2.2 async bridge 2 (master)
	IVA2.2 WUGEN
	MAILBOXES
	McBSP[1, 5]
	McSPI[1, 2, 3, 4]
	MMC/SD/SDIO[1, 2, 3]
	MPU async bridge (slave)
	MPU INTC
	OCM_RAM
	OCM_ROM
	SCM
	SDRC
	SMS
	L3 interconnect
	UART[1, 2]
	SDMA
	Temperature sensor (x2)]
	L4-Core interconnect
DSS	Display subsystem
	Video DAC
CAM	Camera subsystem

Table 3-25. Power Domain Modules (continued)

Power Domain	Modules
PER	UART[3, 4]
	WDTIMER3
	McBSP[2..4]
	GPIO[2..6]
	GPTIMER[2..9]
	L4-Per interconnect
WKUP	GPIO1
	GPTIMER1
	WDTIMER2
	L4-Wake-up interconnect
USBHOST	HS USB host subsystem
EMU	CWT
	DAP-APB
	ETB
	ICEPICK
	TRACEPORT
	L4-EMU interconnect
SMARTREFLEX	SmartReflex1
	SmartReflex2
EFUSE	eFuse farm
DPLL1	MPU DPLL
DPLL2	IVA2.2 DPLL
DPLL3	CORE DPLL
DPLL4	Peripherals DPLL
DPLL5	Peripherals DPLL2

3.5.2.1.3 Memory and Logic Power Management

Device power domains can have separate control for logic and memory. This depends on the power domain implementation in the device (for details, see Section 3.5.2.2, *Power Domain Implementation*).

Generally, separate switches allow separate management of the logic and memory power states in a power domain.

Memory banks in the MPU (L2 cache), IVA2 (L1, L1 flat, L2, L2 flat), CORE (CORE memory banks 1 to 6), SGX, CAM, DSS, USBHOST, and EMU power domain memories have their own voltage and power control, independent of the logic. However, the user must ensure that memory states are programmed consistently with the logic state.

MPU L1 cache memory does not have an independent control and is supplied with the MPU logic.

CORE memory banks 3,4, 5, and 6 are associated to the domain power state and controlled with the domain logic.

MPU and IVA2 memories are supplied by a common LDO (VDD4). CORE, SGX, CAM, DSS, USBHOST, and EMU memories are supplied by another LDO (VDD5).

3.5.2.1.4 Retention Till Access (RTA) Memory Feature

Most high-density memories within the device support the RTA feature. It consists of putting automatically part or entire memory array into retention when no access is made to the corresponding locations. This is managed within the memory bank, by the hardware and is completely transparent to the user software. As a consequence, RTA memories do not have any retention mode control signal coming from the PRCM.

The RTA feature is controlled (enabled/disabled) from a software-controlled override capability through a bit in the System Control Module (that is, the CONTROL_MEM_RTA_CTRL[0] HD_MEM_RTA_SEL bit field.)

3.5.2.1.5 Power Domain States

Each power domain can be driven by the PRM to four different states, depending on the functional mode required by the user. Power domain states are hardware-defined and depend on the domain clock activity and domain memory/logic switch states.

Table 3-26 defines the power states a power domain can reach in the device.

Table 3-26. Power Domain States

Power State	Power		Clocks
	Logic	Memory	
Active	On	On, retention, or off	On (at least one)
Inactive	On	On, retention, or off	Off (all clocks)
Retention (CSWR)	On	Retention or off	Off (all clocks)
Retention (OSWR)	Off/RFF		
Off	Off	Off	Off (all clocks)

NOTE:

- Closed-switch retention (CSWR): Full domain logic supply is maintained, and supply voltage can be dropped to minimize leakage.
- Open-switch retention (OSWR): Full domain logic is switched off, but the context is saved for modules that embed RFFs.
- Throughout the rest of this chapter, when reference is made only to retention state without explicitly stating whether it is CSWR or OSWR, then the description applies to the two retention states.

In CSWR and OSWR, memories are put in retention or can also be switched off.

3.5.2.1.6 Power State Transitions

For each power domain, the PRM manages all transitions controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention.

As previously mentioned, a power domain is characterized by different power states: Active, inactive, retention, and off.

A transition is a passage from one state to another.

Two types of power state transitions are possible:

- Sleep: Moving from a higher consumption power state (active) to a lower consumption power state (inactive, retention, or off)
- Wake-up: Moving directly from a lower consumption power state (inactive, retention, or off) to the active power state

For instance, a power domain with initiators and target modules in standby and idle modes operates an active-to-inactive transition. It is then ready to operate an inactive-to-retention or off transition, depending on the requirements.

The device supports six transitions:

- Active to inactive
- Inactive to active
- Active to retention
- Retention to active
- Active to off

- Off to active

3.5.2.1.7 Device Power Modes

A device power mode is a specific functional combination of the power states of all the power domains of the device.

Unlike power domain states (see Section 3.5.2.1.5), device power modes are not hardware-defined; they are defined by software as relevant combinations of the power domain states.

There are two types of device power modes:

- Active: Any valid combination of power domain states in which one or several domains are still active, regardless of whether any software is running
- Standby: Any valid combination of power domain states in which all the domains are in inactive, retention, or off state

NOTE: All power domain states are hardware-supported, thereby preventing electrical damage to the device. However, software ensures that the power domain states are set correctly, to result in a valid device power mode and ensure correct functioning.

3.5.2.1.8 Isolation Between Power Domains

When switching a power domain from one state to another, the PRCM module automatically manages domain output isolation to prevent electrical damage.

This mechanism is hardware-supervised and does not require software action.

3.5.2.2 Power Domain Implementation

3.5.2.2.1 Device Power Domains

Table 3-27 summarizes the power mode implementation in the device and the control granularity for each power and memory domain.

Table 3-27. Domain Power Control Summary

Functional Domain or Subsystem	Power Domain	PRCM Power Control Type
MPU	MPU	Logic on-off
	NEON	Logic on-off
	CORE	Logic on-off
	EMU	Logic on-off
	L1 cache SRAM	Logic on-off
	L2 cache SRAM	On-off BB retention
IVA2.2	IVA2	Logic on-off Memory tags retention
	CORE	Logic on-off Logic retention
	L1 cache SRAM	On-off BB retention
	L1 flat cache SRAM	On-off BB retention
	L2 cache SRAM	On-off BB retention
	L2 flat cache SRAM	On-off BB retention

Table 3-27. Domain Power Control Summary (continued)

Functional Domain or Subsystem	Power Domain	PRCM Power Control Type
	Misc SRAM	Logic on-off
All MPU and IVA2.2 memories		LDO retention
GRAPHICS	SGX	Logic on-off
	Misc SRAM	Logic on-off
DISPLAY	DSS	Logic on-off
	Misc SRAM	Logic on-off
CAMERA	CAM	Logic on-off
	Misc SRAM	Logic on-off
USBHOST	USB	Logic on-off
	Misc SRAM	Logic on-off
CORE (interconnect, memory controllers, peripherals)	CORE	Logic on-off Logic retention
	SRAM bank 1	On-off BB retention
	SRAM bank 2	On-off BB retention
	OSWR SRAM 3	Logic on-off BB retention
	CSWR SRAM bank 4	On-off BB retention
PERIPHERALS	PER	Logic on-off Logic retention
WKUP	WKUP	none
EMULATION	EMU	Logic on-off
	ETB SRAM	On-off BB retention
SmartReflex	SR1, SR2	Logic on-off
EFUSE	eFuse farm	none
MPU DPLL	DPLL1	Logic on-off
IVA2.2 DPLL	DPLL2	Logic on-off
CORE DPLL	DPLL3	Logic on-off
Peripherals DPLL	DPLL4	Logic on-off
Peripherals DPLL2	DPLL5	Logic on-off

NOTE:

- BB: Back-bias or local memory retention
- OSWR: Open-switch retention
- CSWR: Closed-switch retention
- LDO retention: All memories are in BB mode and the memory array is dropped down.
- Logic on-off: Memory is controlled with the logic (and does not support retention).
- OSWR SRAM bank 3: Corresponds to memories that must be retained when the CORE OSWR mode is activated (the CORE context is maintained only by keeping RFFs alive). These memories are scratchpad, SDMA, and SMS.
- CSWR SRAM bank 4: Corresponds to memories that are retained only in case of CSWR (all logic is maintained with reduced voltage). These memories are USB and MAILBOXES.

The CORE power domain has six memory blocks. Of these six, the power state of only two memory blocks, SRAM bank 1 and SRAM bank 2, can be configured vis-a-vis the domain power state through software setting of the corresponding bit fields in the PRCM.PM_PWSTCTRL_CORE register. The power states of the rest of the memory banks are automatically controlled by the PRCM module (hardware-controlled) and no software setting is possible.

Memory bank 5 of the CORE power domain is used for the USB TLL module save and restore operations. (see Section 3.5.4.6, *USBHOST/USBTLL Save-and-Restore Management*). Similarly, the memory bank 6 is for the system control module save and restore feature (see Chapter 13, *System Control Module*).

NOTE: Before initiating a domain sleep transition (ON to OFF) on the MPU and CORE power domains, the CORE memory banks must be configured to automatically switch to ON power state when the CORE power domain wakes up (OFF to ON). This is required for correct booting.

This is done by setting the PM_PWSTCTRL_CORE[19:18] MEM2ONSTATE bit field to 0x3 and the PM_PWSTCTRL_CORE[17:16] MEM1ONSTATE bit field to 0x3.

3.5.2.2.2 Power Domain Memory Status

The PRCM module logs the memory status in the SCM.CONTROL_SEC_STATUS register. The memory status is logged for CORE power domain memory banks 1 and 2 (OCM RAM) and for the L1 and L2 caches of the MPU.

Two statuses are logged for each memory bank:

- Memory is destroyed: The memory array is powered down.
- Memory is not accessible: The memory array is powered down or is in retention.

For information about the SCM, see Chapter 13, *System Control Module*.

3.5.2.2.3 Power Domain State Transition Rules

As previously described, a power domain can reach different states. These states are linked to the power applied to the domain and to the domain clock activity.

Any power state transition always depends on and starts with power domain clock activity control. Any active clock in a power domain sets the domain as active (see Section 3.5.2.2.1). Therefore, a sleep transition always starts by shutting down the power domain clocks. For more information about power domain clock controls, see Section 3.5.3, *Clock Manager Functional Description*.

When all clocks are shut down in a power domain, transitions from inactive-to-off or inactive-to-retention can occur.

Similarly, when a wake-up transition occurs between a lower-power domain state and a higher one, the transition to active state becomes effective when the required clocks are restarted.

Section 3.5.4, *Idle and Wake-Up Management*, describes sleep and wake-up transitions.

3.5.2.2.4 Power Domain Dependencies

Besides the inner conditions to operate a state transition on a single power domain, the device offers hardwired and software-programmable dependencies between the power domains.

Two kinds of dependencies exist:

- Sleep dependencies: Used to start a sleep transition on a power domain only if the related power domains are in mute mode (not requesting any service from the linked power domain)
- Wake-up dependencies: Used to initiate a wake-up transition on a power domain as a consequence of a linked power domain wake-up transition

Two dedicated sets of registers (PRCM.CM_SLEEPDEP_<domain> and PRCM.PM_WKDEP_<domain>) allow the setting of programmable dependencies.

Section 3.5.4.5, *Sleep and Wake-Up Dependencies*, summarizes the possible dependency combinations between power domains.

3.5.2.2.5 Power Domain Controls

3.5.2.2.5.1 Power Domain Hardware Control

Each power domain in the device is controlled by a dedicated power state controller (PSCON) in the PRCM module.

When a state transition occurs for a given power domain, the related PSCON automatically manages the sequence.

The following sequences are for information only. They do not require software control and are hardware-managed by the PSCON.

- Active-to-retention transition:
  1. The PSCON isolates the power domain outputs.
  2. The PSCON saves the flip-flop content.
  3. The PSCON opens the power switch.
- Retention-to-active transition:
  1. The PSCON closes the power switch.
  2. The PSCON restores the flip-flop content.
  3. The PSCON deactivates the isolation of the power domain outputs.
- Active-to-off transition:
  1. The PSCON isolates the power domain outputs.
  2. The PSCON opens the power switch.
- Off-to-active transition:
  1. The PSCON closes the power switch.
  2. The PSCON deactivates the isolation of the power domain outputs.

Device power domain implementation also depends on hardwired dependencies, both sleep and wake-up transitions, between power domains. This means a single power domain transitions from one power state to another depending on the states and transitions of the linked domains.

For details about the dependencies between power domains, see Section 3.5.4, *Idle and Wake-Up Management*, and Section 3.6, *Basic Programming Model*.

3.5.2.2.5.2 Power Domain Software Controls

If all conditions are met to initiate a power domain state transition (all the modules are idle/standby and the related clocks are shut down), the PRCM module automatically manages the transition according to the following settings:

- Dependencies setting: The PRCM.CM_SLEEPDEP_<domain> registers and PRCM.PM_WKDEP_<domain> registers are used to set/clear programmable dependencies between power domains.

  Not all dependencies are programmable by software; some are hardwired and thus do not allow any control. For more information about the dependencies between power domains, see Section 3.5.4, *Idle and Wake-Up Management*, and Section 3.6, *Basic Programming Model*.
- Power state transitions setting: The transitions of each power domain state can be controlled by software through a set of dedicated status registers (PRCM.PM_PWSTCTRL_<domain_name>) that allow the configuration of the power state that the domain enters after completing a transition (PRCM.PM_PWSTCTRL_<domain_name>[1:0] POWERSTATE bit field). These status registers are used to check the current state of the logic and memories in a power domain and to learn about any ongoing state transition.

  Also, if the power domain offers different settings for logic and memory, the PRCM.PM_PWSTCTRL_<domain_name> registers allow selection of the state to which the logic and memory go when the power domain is put in retention. They also allow selection of the state to which

the memory will go when the power domain is put into on state.

These features depend on each power domain implementation. For details, see Section 3.6, *Basic Programming Model*, and Section 3.8, *PRCM Registers Manual*.

- Event generator: Three registers (PRCM.PM_EVGENCTRL_MPU, PRCM.PM_EVGENONTIM_MPU, and PRCM.PM_EVGENOFFTIM_MPU) let the MPU power domain be switched between on and off (or placed in inactive mode). The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers set the durations of the on and off modes, respectively.

  For details, see Section 3.6, *Basic Programming Model*, and Section 3.8,*PRCM Registers Manual*.

3.5.3 PRCM Clock Manager Functional Description

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

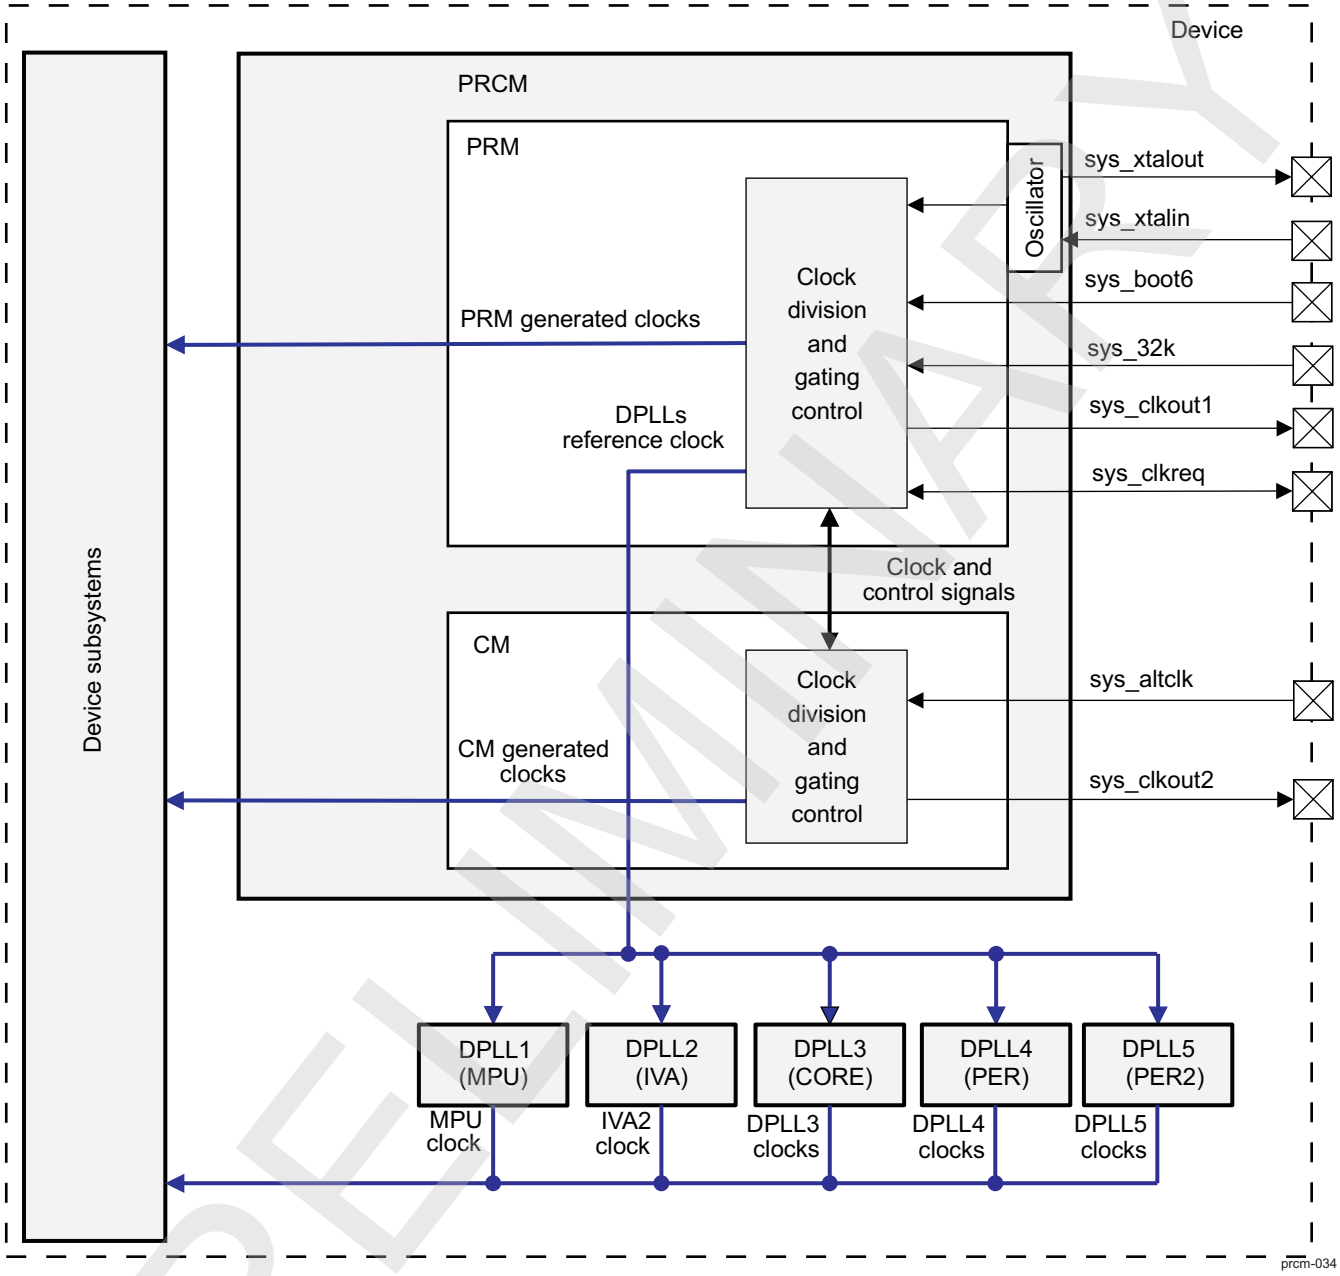
NOTE: For more information about clock distribution and control, see the device clock tree tool.

3.5.3.1 Overview

The PRCM module provides control for clock generation, division, distribution, synchronization, and gating. It distributes the clock sources to all modules in the device.

The device-level clock generation is handled by an internal oscillator (the system clock oscillator) and DPLLs; clock division and gating are handled by the PRM and the CM sections of the PRCM module. Figure 3-35 shows the high-level clock-management scheme in the device.

Figure 3-35. PRCM Clock Manager Overview



3.5.3.1.1 *Interface and Functional Clocks*

The PRCM module propagates two kinds of clocks:

- Interface clock: Ensures proper communication between any module and the system interconnects (level 3 [L3] or level 4 [L4]). In most cases, the interface clock supplies the interface and registers of the module. For some modules, the interface clock is also used as the functional clock.
- Functional clock: Supplies the functional part of a module or subsystem. In some cases, a module or subsystem can require several functional clocks.

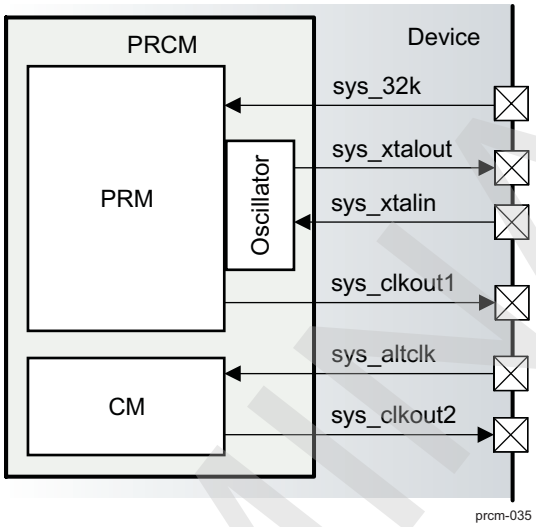
To be operational, a module requires a functional clock(s); to communicate with other modules, it requires an interface clock. For example, the functional clock of a general-purpose timer (GPTIMER) must be active for it to run, but its interface clock can be turned off.

A module can use one or more optional functional clocks. Because an optional functional clock is used only for specific features of the module, it can be shut down without stopping the module activity (for example, 54 MHz for the DSS power domain and 96 MHz for the CAM power domain).

3.5.3.2 External Clock I/Os

Figure 3-36 shows the external clock I/Os of the device.

Figure 3-36. External Clock I/O



3.5.3.2.1 External Clock Inputs

3.5.3.2.1.1 32-kHz Always-On Clock

The sys_32k input pin supplies the 32-kHz always-on clock (32K_FCLK clock). This clock is used for low-frequency operation (timers, debouncing, etc.). It also supplies the WKUP power domain for operation in the lowest power mode.

3.5.3.2.1.2 High-Frequency System Clock

The high-frequency system clock (SYS_CLK) is supplied to the device from an external clock source through the sys_xtalin input pin or is generated internally by a local system clock crystal oscillator. In the latter case, a crystal is connected between the sys_xtalout and sys_xtalin device pins. The sys_boot[6] pin sets the oscillator operating mode (see Figure 3-14).

The source system clock can be 12, 13, 16.8, 19.2, 26, or 38.4 MHz and can be divided by 2 to provide the standard system clock frequencies (using internal system clock divider configuration in the PRCM.PRM_CLKSRC_CTRL[7:6] SYSCLKDIV bit field). It supplies the reference to the DPLLs and is also used by several modules. The system clock is activated in the device after the device power-on reset is released by the reset manager in the PRCM module.

The source-clock selection register (the PRCM.PRM_CLKSEL [2:0] SYS_CLKIN_SEL bit field) is set by the software to identify the input frequency of the system clock.

Table 3-28 lists the system clock input configurations.

Table 3-28. System Clock Input Configurations

Input Source	Device Pin Mapping	Description
Quartz	sys_xtalin and sys_xtalout	Internal oscillator is enabled.
Square clock (1.8-V CMOS signal)	sys_xtalin (sys_xtalout is not connected)	Internal oscillator is bypassed.

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the internal oscillator is used (oscillator mode) or an external clock source is supplied to the sys_xtalin input pin (bypass mode).

3.5.3.2.1.3 Alternate Clock

The sys_altclk pin can provide an additional 54-MHz, 48-MHz, or any other frequency clock.

3.5.3.2.2 External Clock Outputs

The device can output two clocks externally:

- sys_clkout1 can output an oscillator clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) at any time. The output oscillator clock can be controlled by software or externally using sys_clkreq control. When the device is in off state, sys_clkreq can be asserted to enable the oscillator and activate sys_clkout1 without waking up the device. The off state polarity of sys_clkout1 is programmable.
- sys_clkout2 can output CM_SYS_CLK (12, 13, 16.8, 19.2, 26, or 38.4 MHz), CORE_CLK (CORE DPLL output), or 96-MHz or 54-MHz clocks. It can be divided by 2, 4, 8, or 16, and its off state polarity is programmable. This output is active only when the CORE power domain is active. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock.

3.5.3.2.3 Summary

Table 3-29 summarizes the external clock I/O.

Table 3-29. External Clock I/Os

Name	I/O [1]	Source/Destination	Description
sys_xtalin	I	Oscillator	Main input clock. Crystal oscillator clock (only at 12, 13, 16.8, or 19.2 MHz) or CMOS digital clock (at 12, 13, 16.8, 19.2, 26, or 38.4 MHz).
sys_xtalout	O	Oscillator	Output of oscillator
sys_clkout1	O	PRCM	Configurable output clock 1
sys_clkout2	O	PRCM	Configurable output clock 2
sys_32k	I	PRCM	32-kHz clock input
sys_altclk	I	PRCM	Additional selectable clock source for UARTs or NTSC/PAL. It can be 54 MHz, 48 MHz, or any frequency.

(1) I = Input, O = Output

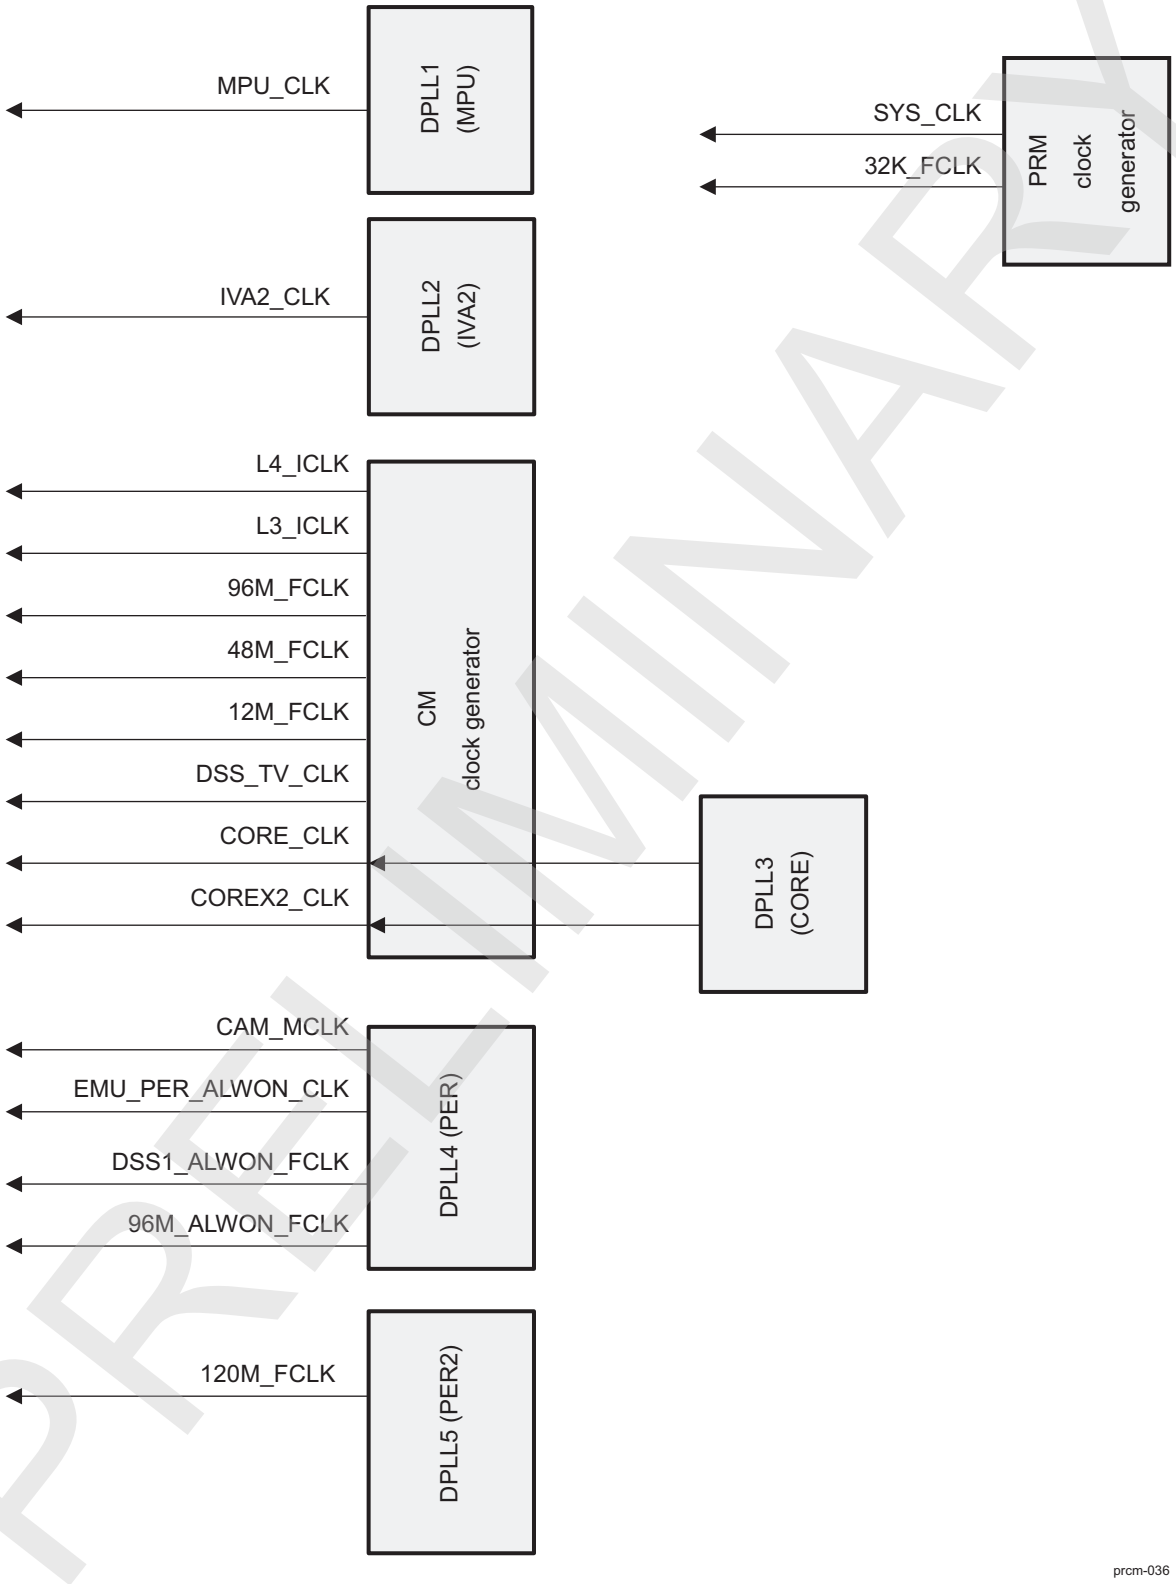
3.5.3.3 Internal Clock Generation

The device generates internal clocks from following sources:

- PRM
- CM
- DPLLs

Figure 3-37 shows the internal clock-generation scheme of the device.

Figure 3-37. Internal Clock Sources



3.5.3.3.1 PRM

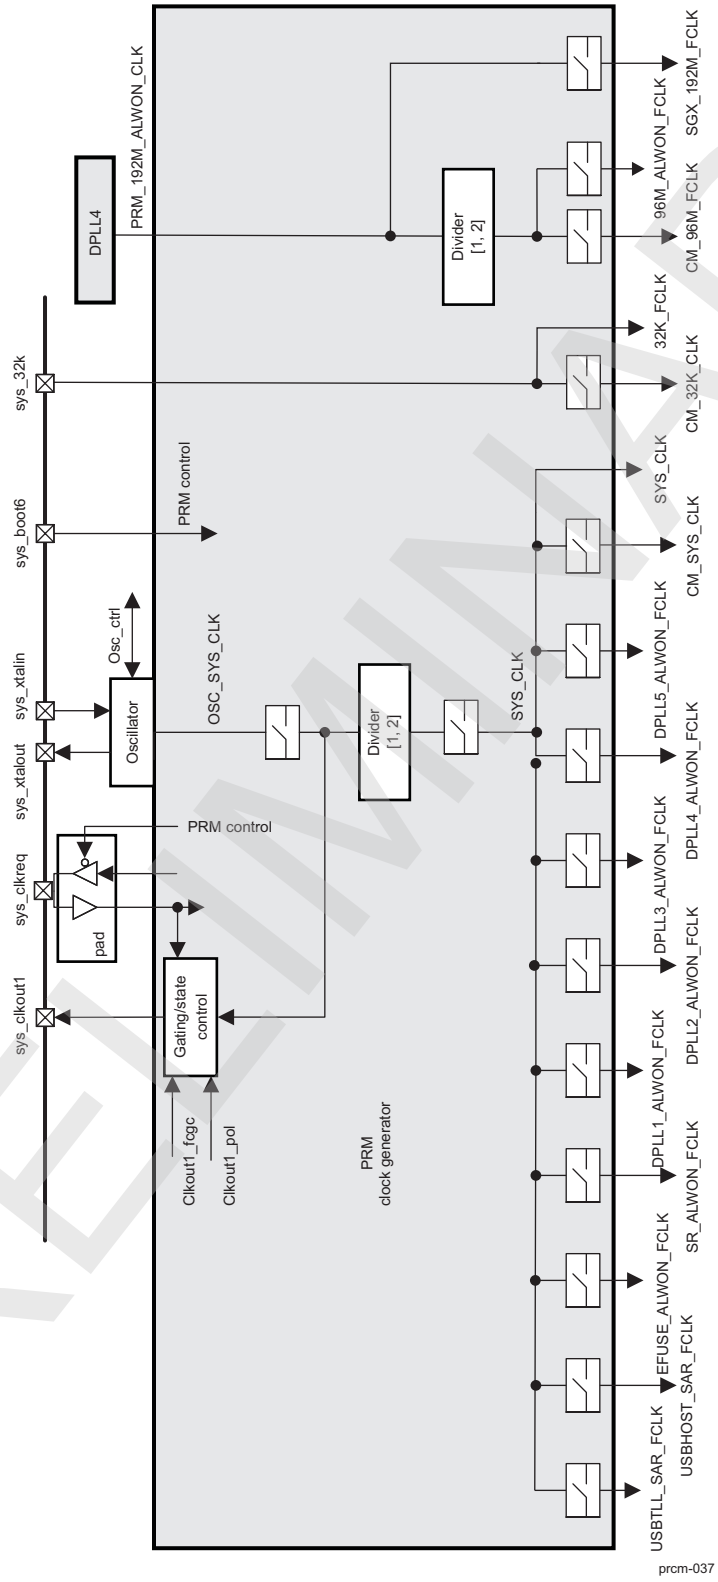
The PRM resides in the WKUP power domain. It handles the generation of the 32-kHz low-frequency clocks and the high-frequency system clocks from the SYS_CLK. It also manages the clock oscillator and the external clock output sys_clkout1.

SYS_CLK is generated by the internal oscillator or supplied as the external clock signal on the sys_xtalin pin. It supplies most of the clocks in the device. Some of the device clocks sourced by SYS_CLK are always powered (clocks are present even when the CORE power domain is in off state). SYS_CLK is also the source of the WKUP power domain interface clocks.

It also handles the gating and distribution of the 96-MHz clock from DPLL4 to the CM and PER power domain modules.

Figure 3-38 is a functional overview of the PRM. The other clocks in the figure are explained in the following sections.

Figure 3-38. PRM Clock Generator



3.5.3.3.2 CM

The CM clock generator generates interface clocks and peripheral functional clocks for most of the modules. It also controls DPLL3, DPLL4, and the external peripheral clock output sys_clkout2 (see Figure 3-39).

The CM is in the CORE power domain, which can be powered off. When the CORE power domain is powered off, the clocks are not available, and their off state is latched. The DPLL controls are also latched. The RFF architecture ensures that the full CM setting is saved when the CORE power domain goes to retention state, and is transparently restored when it reactivates.

DPLL3 receives SYS_CLK from the PRM module and generates CORE_CLK through the CM. CORE_CLK is the source for the interface clocks (L3 and L4) and the functional clock . The L3 and L4 interface clocks supply the device interconnects and all module interface clocks. The L4 clock is divided for USB (full-speed clock limitation at 50 MHz) and to supply the reset managers (PRM) in the WKUP power domain. The clocks derived from CORE_CLK are fully balanced over the device.

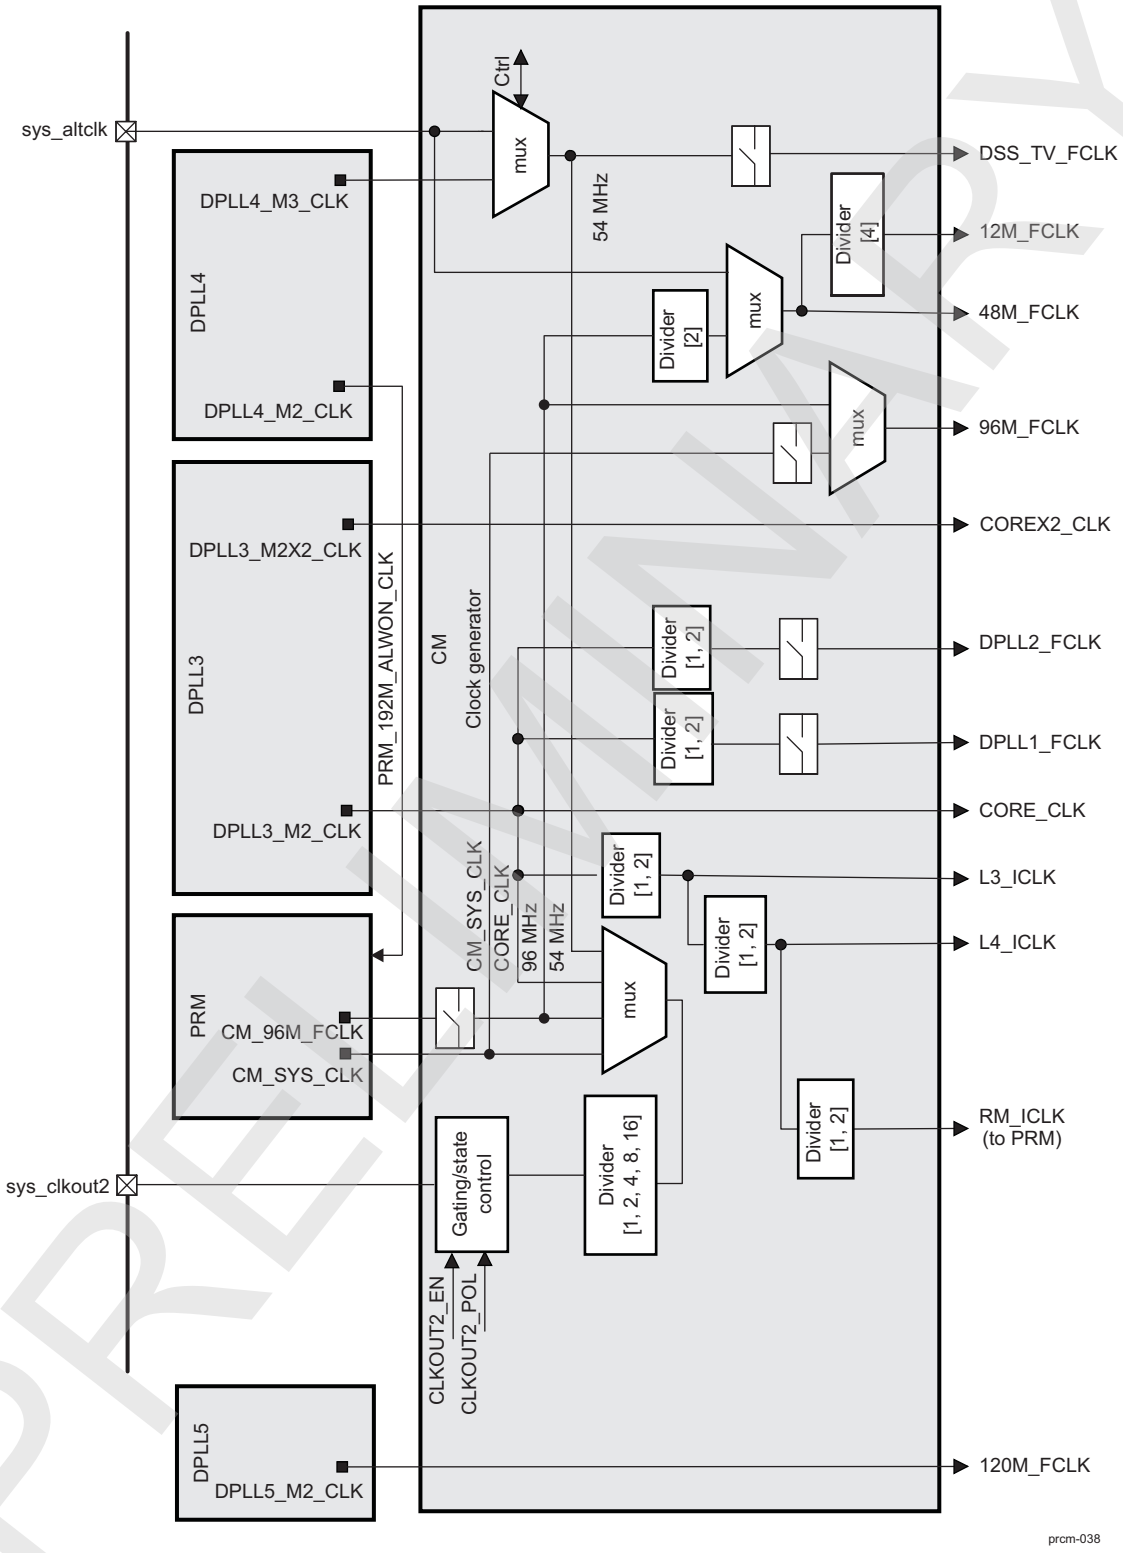
The 96M_FCLK, 48M_FCLK, and 12M_FCLK clocks are functional unbalanced clocks for a number of modules in the CORE and PER power domains.

The functional 96-MHz clock path can be bypassed with SYS_CLK to allow a peripheral such as I^2C to function while the DPLL4 is not powered on. The default configuration after initial power on is bypassed with the system clock. Software must switch to the DPLL-generated clock after programming the system settings.

The 96-MHz clock input from the PRM to the CM (CM_96M_FCLK) is internally gated by the CM.

Figure 3-39 is the functional overview of the CM.

Figure 3-39. CM Clock Generator Functional Overview



3.5.3.3.3 DPLLs

To generate high-frequency clocks, the device supports five on-chip DPLLs controlled directly by the PRCM module:

- DPLL1 (MPU)
- DPLL2 (IVA2)
- DPLL3 (CORE)
- DPLL4 (PER)
- DPLL5 (PER2)

NOTE: This chapter discusses only DPLL1 to DPLL5, because they are directly controlled by the PRCM module. Chapter 7, *Display Subsystem*, discusses the DPLLs in the display subsystem.

The DPLLs are of two types. Type A DPLLs are DPLL1, DPLL2, DPLL3 and DPLL5. Type B DPLL is DPLL4.

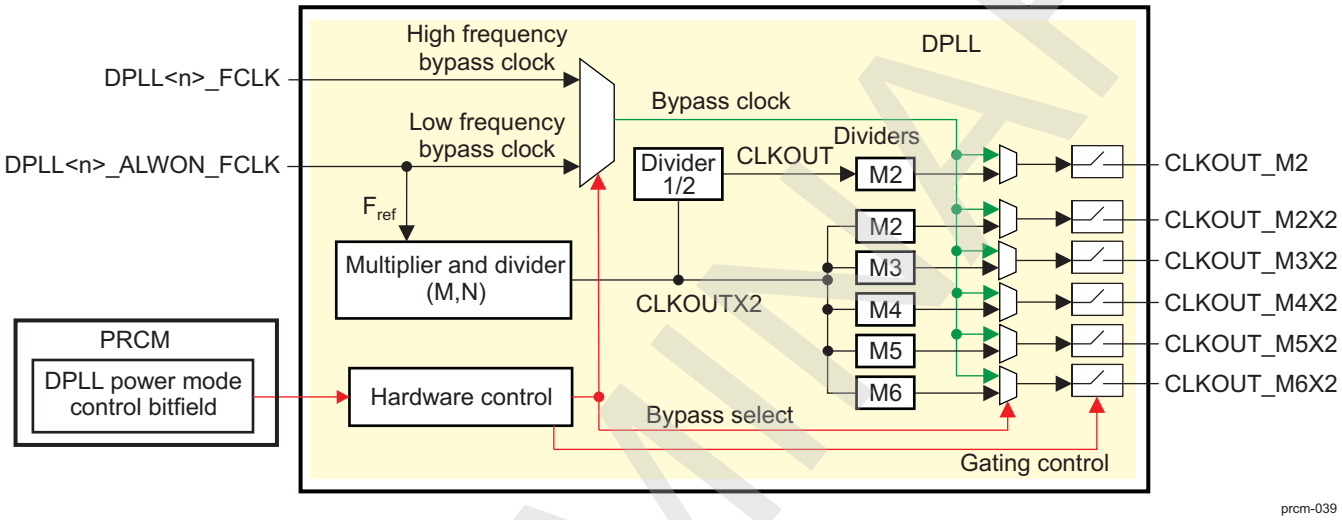
3.5.3.3.3.1 Type A DPLLs

Type A DPLLs that are controlled directly by the PRCM module:

- DPLL1 (MPU)
- DPLL2 (IVA2)
- DPLL3 (CORE)
- DPLL5 (PER2)

Figure 3-40 shows the functional architecture of a generic DPLL.

Figure 3-40. Generic DPLL Functional Diagram



Depending on its hardware configuration, the DPLL can receive one or two clock inputs.

When the DPLL has two clock inputs, it uses one as the reference clock (F_{ref}) to generate the high-frequency clock; the second one serves as the bypass clock when the DPLL is in bypass mode (not locked and generating the high-frequency clock). For example, DPLL1 and DPLL2 receive the high-frequency bypass clock from the DPLL3 output, and the reference clock from the PRM module.

When the DPLL has only one clock input, it uses that clock input as the reference clock and bypass clock. For example, DPLL3, and DPLL5 receive only one input clock from PRM module, and it is used as the reference and the bypass clock.

It internally generates two main clocks according to the following equations:

- CLKOUTX2 = (F_{ref} x 2 x M)/(N+1)
- CLKOUT = CLKOUTX2/2

where M is an 11-bit multiplier and N is a 7-bit divider.

NOTE: When M is set to 0 or 1, the DPLL is forced to bypass mode.

The internal clocks (CLKOUT and CLKOUTX2) of the DPLL can then be used to generate six independent output clocks:

- CLKOUT_M2 = CLKOUT/M2
- CLKOUT_M2X2 = CLKOUTX2/M2
- CLKOUT_M3X2 = CLKOUTX2/M3
- CLKOUT_M4X2 = CLKOUTX2/M4
- CLKOUT_M5X2 = CLKOUTX2/M5
- CLKOUT_M6X2 = CLKOUTX2/M6

where M2, M3, M5, and M6 are additional dividers for the DPLL-synthesized clock.

The output clock frequencies defined by these equations are generated by the DPLL only when it is locked. When the DPLL is in bypass mode, however, all clock outputs run at the bypass clock frequency. The bypass clock can be a high-frequency bypass clock (only for DPLL1 and DPLL2) or the low-frequency reference clock.

The DPLL also provides an independent clock-gating signal for each of the six output clocks. The PRCM module provides the DPLL with a clock-gating control signal, and the DPLL returns a clock activity status signal indicating whether the output clock is effectively gated or running.

For an explanation of the DPLL multiplier, divider settings, and gating controls, see Section 3.5.3.6, *DPLL Control*.

Each clock-generating DPLL of the device has the following features:

- Independent power domain
- Control by the CM
- Fed by always-on SYS_CLK with independent gating control for the SYS_CLK
- Analog part supplied by a dedicated power supply (VDDPLL and VDDADAC at 1.8 V) and an embedded LDO to eliminate 1-MHz noise
- Up to six independent output dividers for simultaneous generation of multiple output clocks with different frequencies

3.5.3.3.3.1.1 DPLL1 (MPU) and DPLL2 (IVA2)

DPLL1 and DPLL2 are in the MPU and IVA2.2 subsystems, respectively. The DPLLs supply the source clocks for their respective subsystems, which use the source clocks to internally generate all subsystem clocks.

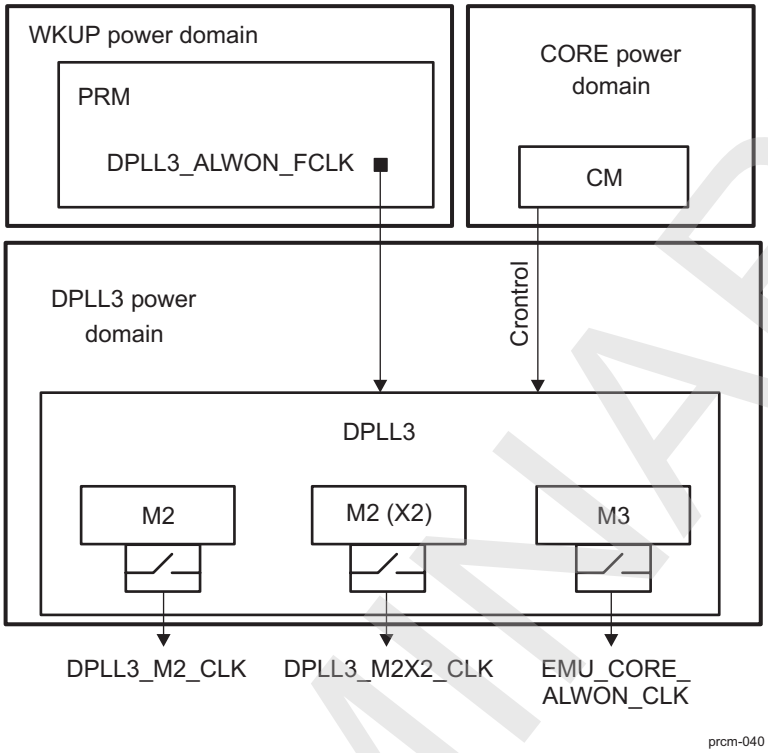
DPLL1 and DPLL2 each use a reference clock (DPLL1_ALWON_FCLK and DPLL2_ALWON_FCLK, respectively) to produce their synthesized clocks. They receive these reference clocks from the PRM module, and their high-frequency bypass clocks (DPLL1_FCLK and DPLL2_FCLK, respectively) from the CM. The reference clock is SYS_CLK, and the high-frequency bypass clock is CORE_CLK.

To save on DPLL power consumption by the processors, the high-frequency bypass input clock from DPLL3 (CORE) is used when the DPLLs are set to bypass mode (statically, or dynamically during relock time) or when the processors are not required to run faster than at L3 clock speed. This use of the high-frequency bypass input clock also optimizes the performance of the DPLLs during frequency scaling.

3.5.3.3.3.1.2 DPLL3 (CORE)

Figure 3-41 is a block diagram of DPLL3.

Figure 3-41. DPLL3 Clocks

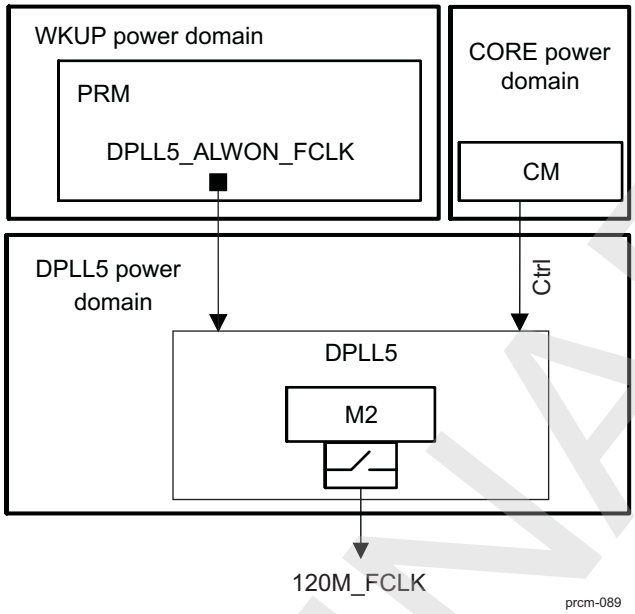


DPLL3 receives its reference clock (DPLL3_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL3 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL3 supplies the source clock for all interfaces and a few functional clocks for the device modules. It is also the source of the emulation trace clock. While the CORE power domain is on, the output of DPLL3 can be used as HS bypass clock input to DPLL1 and DPLL2.

3.5.3.3.3.1.3 DPLL5 (Peripherals)

Figure 3-42 is a block diagram of DPLL5.

Figure 3-42. DPLL5 Clocks



DPLL5 receives its reference clock (DPLL5_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL5 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL5 generates clocks for the peripherals, supplying five clock sources:

- 120-MHz functional clock to the peripheral domain modules

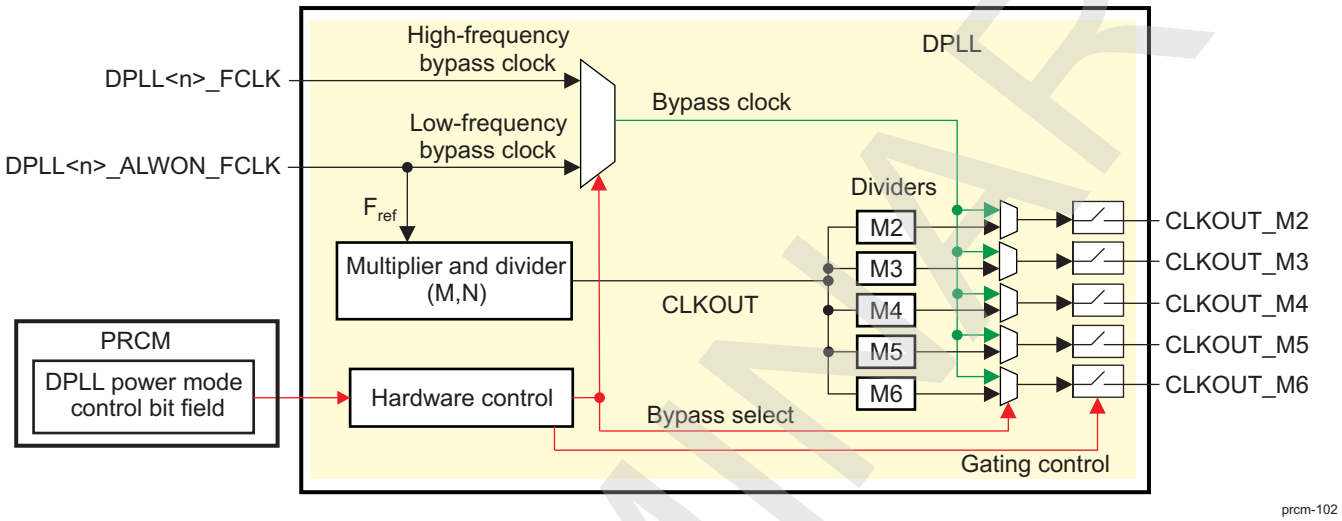
3.5.3.3.3.2 Type B DPLL (Low-Jitter)

To generate high-frequency clocks, the device supports one on-chip Low-Jitter DPLL controlled directly by the PRCM module:

- DPLL4 (PER)

Figure 3-43 shows the functional architecture of DPLL4.

Figure 3-43. DPLL4 Functional Diagram



DPLL4 receives only one input clock from PRM module, and it is used as the reference and the bypass clock.

NOTE: The DPLL4 reference clock can be pre-divided before feeding the DPLL4. This is done in the PRM thanks to a dedicated programmable register PRM_CLKSRC_CTRL[8] DPLL4_CLKINP_DIV.

It internally generates one main clock according to the following equation:

- $CLKOUT = (F_{ref} \times M)/(N+1)$

where M is a 12-bit multiplier and N is a 7-bit divider.

NOTE: When M is set to 0 or 1, the DPLL is forced to bypass mode.

The internal clock (CLKOUT) of the DPLL can then be used to generate five independent output clocks:

- CLKOUT_M2 = CLKOUT/M2
- CLKOUT_M3 = CLKOUT/M3
- CLKOUT_M4 = CLKOUT/M4
- CLKOUT_M5 = CLKOUT/M5
- CLKOUT_M6 = CLKOUT/M6

where M2, M3, M4, M5, and M6 are additional dividers for the DPLL-synthesized clock.

The output clock frequencies defined by these equations are generated by the DPLL only when it is locked. When the DPLL is in bypass mode, however, all clock outputs run at the bypass clock frequency. The bypass clock in DPLL4 can be only the low-frequency reference clock.

DPLL4 requires 2 additional settings than the other DPLLs.

- The user must select which one of the DPLL4's digitally controlled oscilators (DCO) is used depending on the targeted lock frequency. This is done in CM_CLKSEL2_PLL[23:21] DCO_SEL.

- The user must program the DPLL4 sigma-delta divider. This is done in CM_CLKSEL2_PLL[31:24] SD_DIV. This divider value is given by the following equation: SD_DIV = ceiling (CLKOUT/250), where CLKOUT Is in MHz

NOTE: Incorrect programming of the sigma-delta divider will lead to complete non-functionality or poor performance.

The DPLL also provides an independent clock-gating signal for each of the six output clocks. The PRCM module provides the DPLL with a clock-gating control signal, and the DPLL returns a clock activity status signal indicating whether the output clock is effectively gated or running.

For an explanation of the DPLL multiplier, divider settings, and gating controls, see Section 3.5.3.6, *DPLL Control*.

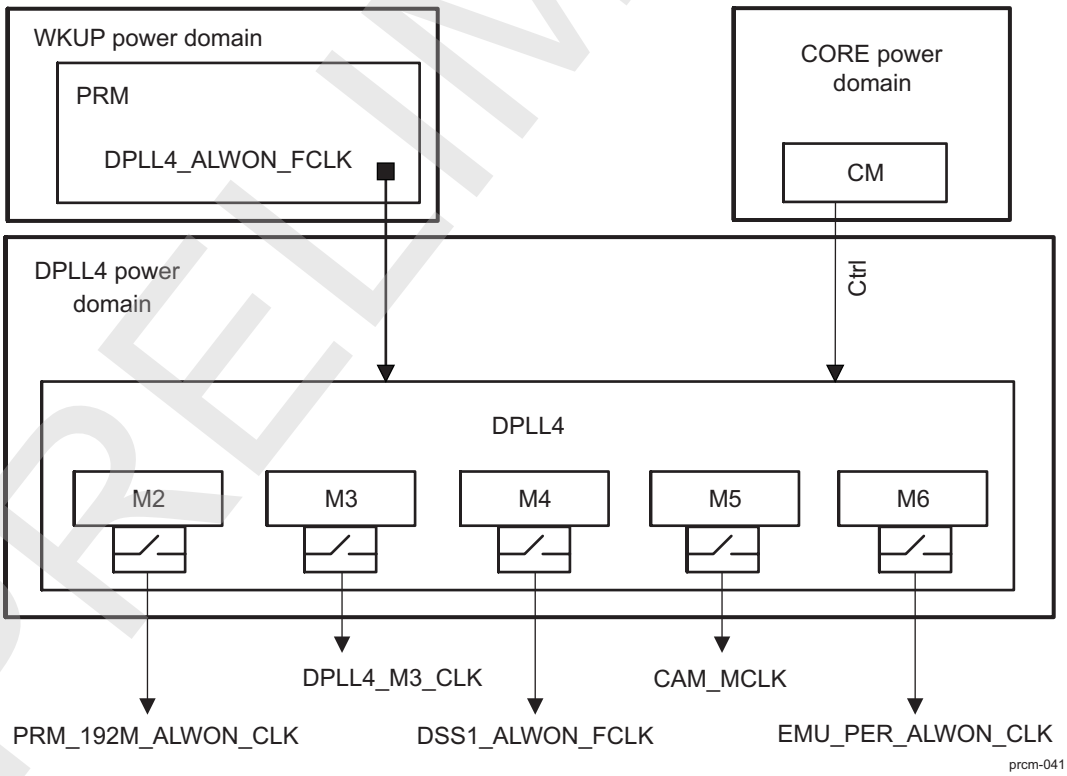
Each clock-generating DPLL of the device has the following features:

- Independent power domain
- Control by the CM
- Fed by always-on SYS_CLK with independent gating control for the SYS_CLK
- Analog part supplied by a dedicated power supply (VDDPLL and VDDADAC at 1.8 V) and an embedded LDO to eliminate 1-MHz noise
- Up to five independent output dividers for simultaneous generation of multiple output clocks with different frequencies

3.5.3.3.3.2.1 DPLL4 (Peripherals)

Figure 3-44 is a block diagram of DPLL4.

Figure 3-44. DPLL4 Clocks



DPLL4 receives its reference clock (DPLL4_ALWON_FCLK), which is the SYS_CLK from the PRM, and can be devided before feeding the DPLL4. This is done in the PRM thanks to a dedicated programmable

register PRM_CLKSRC_CTRL[8] DPLL4_CLKINP_DIV. This divider is intended to be used in case a 13 MHz system clock is used, in order to be able to lock the DPLL4 at 864 MHz. There is a divider that can define the DPLL4 source clock and it is controlled by PRM_CLKSRC_CTRL[8] DPLL4_CLKINP_DIV Ratios: 1, 6.5. DPLL4 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL4 generates clocks for the peripherals, supplying five clock sources:

- 96-MHz always-on source clock for the PRM
- 54-MHz to TV DAC
- Display functional clock
- Camera sensor clock
- Emulation trace clock

The clock outputs to the DSS, PER, and EMU power domains are always on.

3.5.3.3.4 DPLL Clock Summary

Table 3-30 and Table 3-31 summarizes the use of the divided output clocks of the DPLLs in the device.

Table 3-30. Low-Jitter DPLL Output Clocks

	CLKOUT_M2	CLKOUT_M3	CLKOUT_M4	CLKOUT_M5	CLKOUT_M6
DPLL4	X	X(1)	X	X	X

(1) X represents the DPLL clock output used.

Table 3-31. Other DPLL Output Clocks

	CLKOUT_M2	CLKOUT_M2X2	CLKOUT_M3X2	CLKOUT_M4X2	CLKOUT_M5X2	CLKOUT_M6X2
DPLL1	X(1)					
DPLL2	X					
DPLL3	X	X	X			
DPLL5	X					

(1) X represents the DPLL clock output used.

3.5.3.3.5 Summary

Table 3-32 summarizes the source clocks in the device.

Table 3-32. Source-Clock Summary

Clock	External/Internal Source	Clock Generator	Description
32K_FCLK	sys_32k (input pin)	PRM	
SYS_CLK	Oscillator	PRM	System clock. Serves as primary source clock of the device. Also used as functional and interface clock for PRM.
DSS_TV_CLK	DPLL4/sys_altclk (input pin)	CM	DSS TV clock
120M_FCLK	DPLL5	CM	
96M_FCLK	DPLL4	CM	
48M_FCLK	DPLL4/sys_altclk (input pin)	CM	
12M_FCLK	DPLL4/sys_altclk (input pin)	CM	
PRM_192M_ALWON_CLK		DPLL4	Direct from DPLL4
CORE_CLK	DPLL3	CM	DPLL3 clock output frequency
COREX2_CLK	DPLL3	CM	DPLL3 clock output frequency x 2
L3_ICLK	DPLL3	CM	L3 interconnect interface clock
L4_ICLK	DPLL3	CM	L4 interconnect interface clock
MPU_CLK		DPLL1	MPU subsystem source clock
IVA2_ CLK		DPLL2	IVA2.2 subsystem source clock

3.5.3.4 Clock Distribution

3.5.3.4.1 Power Domain Clock Distribution

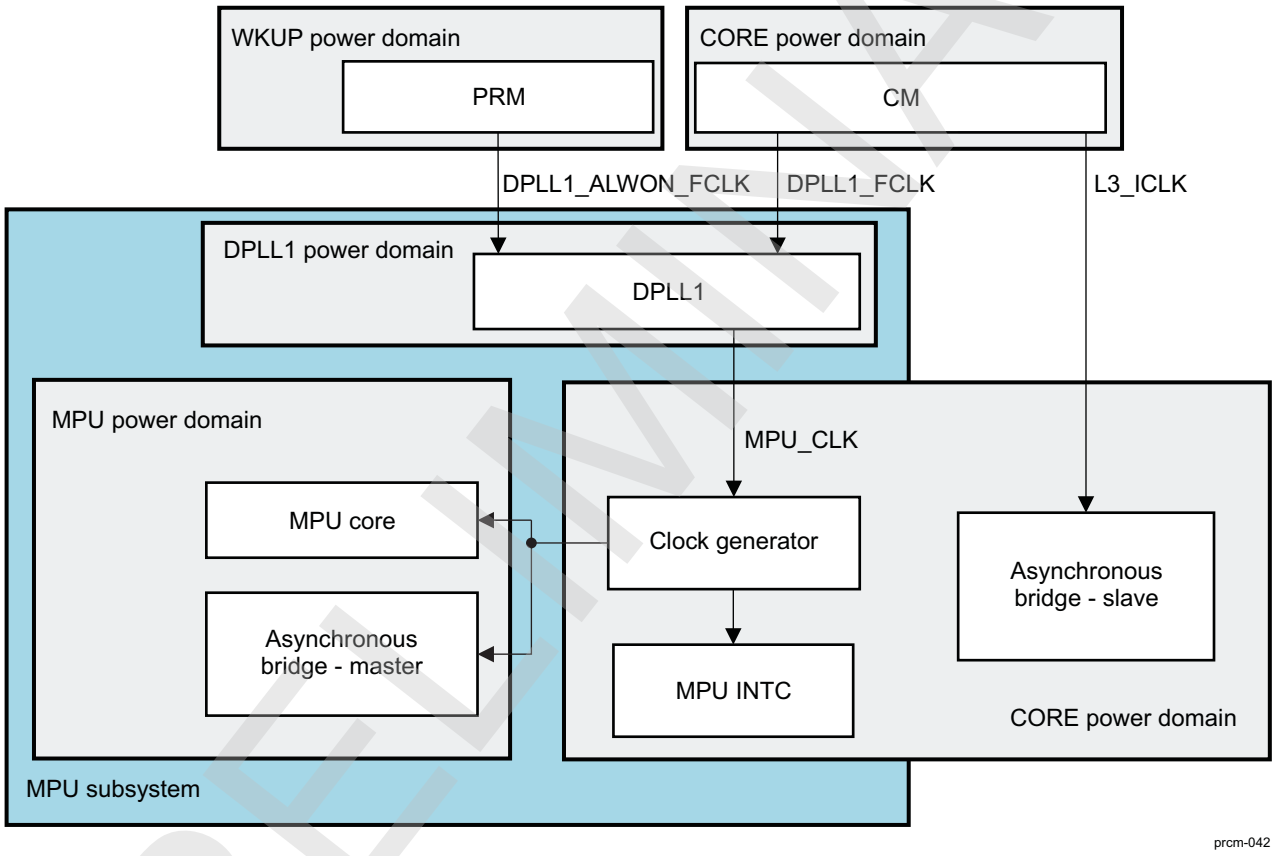
This section describes the PRCM clock distribution over device power domains.

3.5.3.4.1.1 MPU Power Domain

The PRCM module does not directly provide any clock to the MPU power domain. It feeds only DPLL1, which generates MPU_CLK. All clocks are then locally generated by the clock generator in the MPU subsystem.

Figure 3-45 shows the clocking scheme in the MPU power domain.

Figure 3-45. MPU Power Domain Clocking Scheme



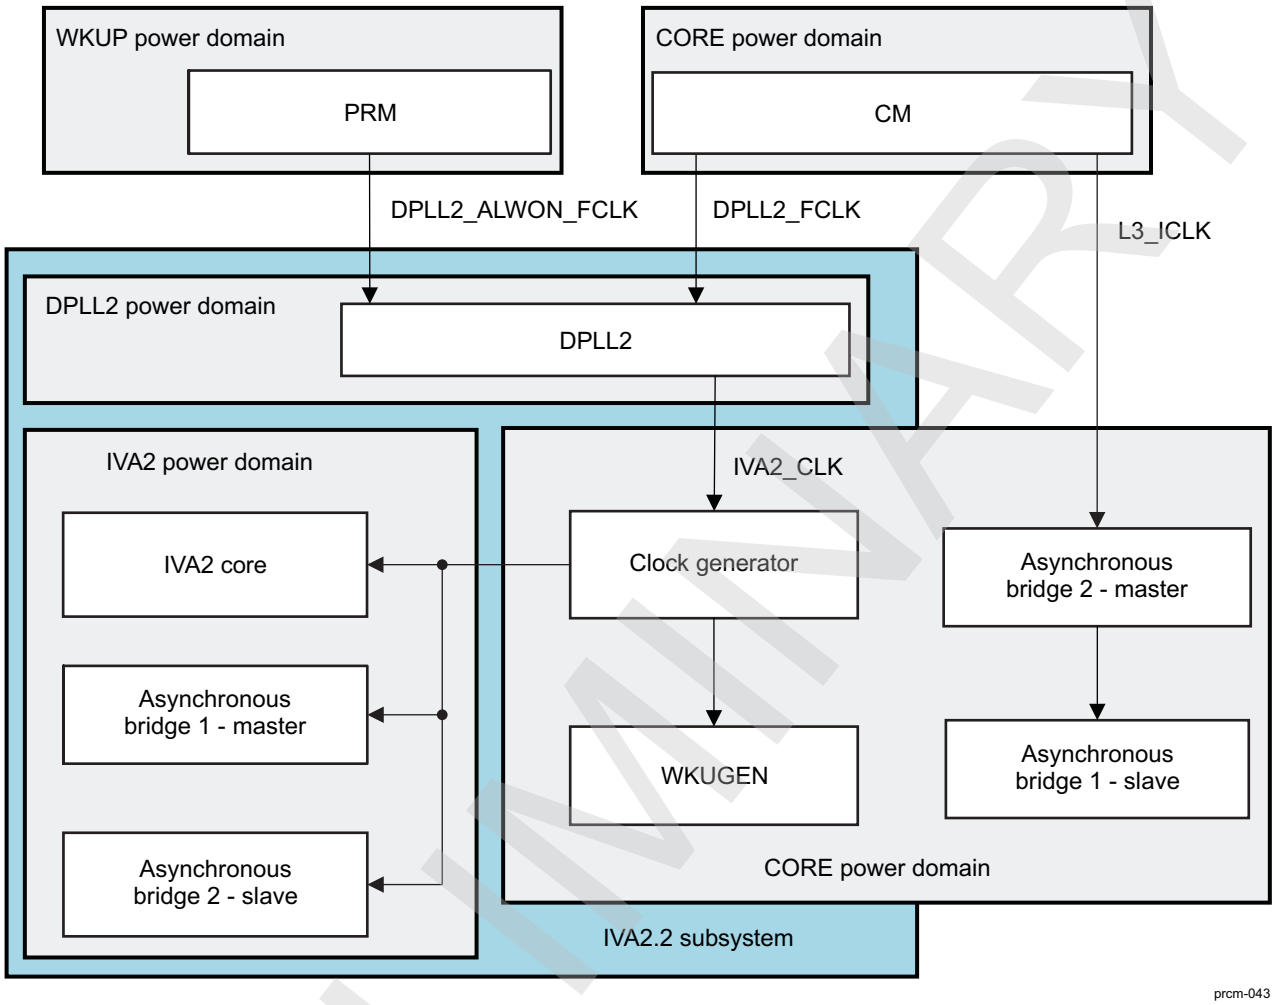
NOTE: ARM_FCLK is sourced by MPU_CLK and has the same frequency. (For more information about ARM_FCLK, see Chapter 4, *MPU Subsystem*).

3.5.3.4.1.2 IVA2 Power Domain

The PRCM module does not directly provide any clock to the IVA2 power domain. It feeds only DPLL2, which generates IVA2_CLK. All clocks are then locally generated by a clock generator in the IVA2.2 subsystem.

Figure 3-46 shows the clocking scheme in the IVA2 power domain.

Figure 3-46. IVA2 Power Domain Clocking Scheme



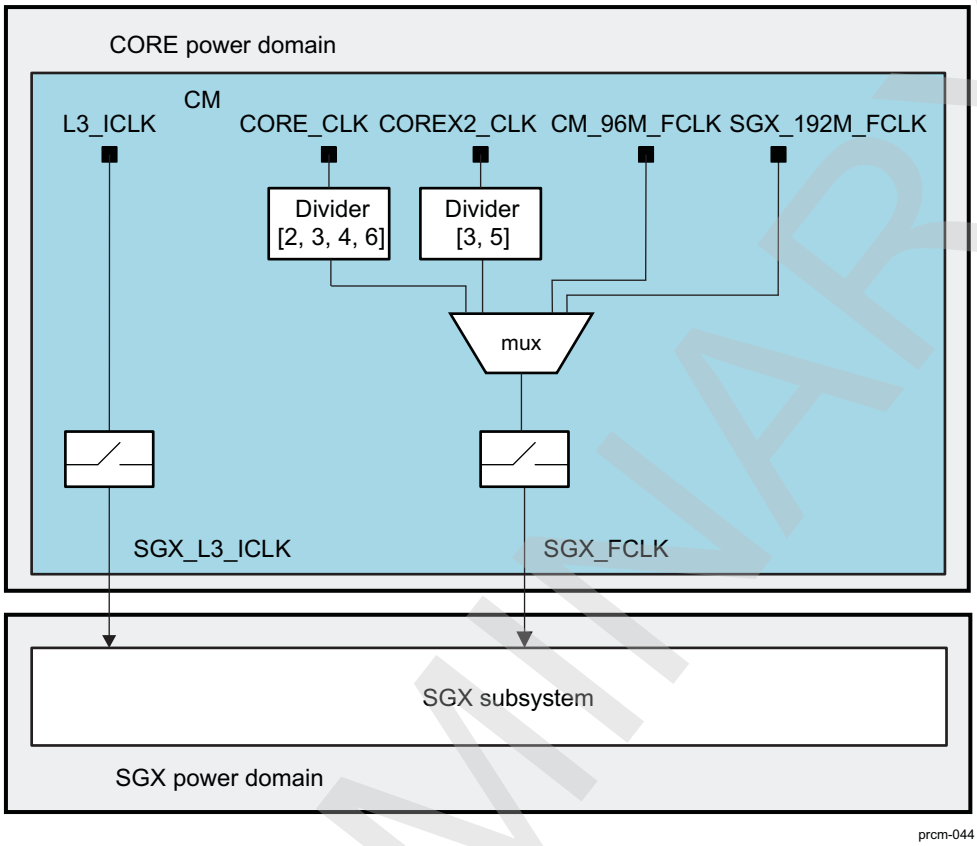
3.5.3.4.1.3 SGX Power Domain

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

The SGX subsystem interface clock is sourced by the L3 clock. The functional clock source can be selected between CORE_CLK, COREX2_CLK, CM_96M_FCLK and SGX_192M_FCLK. When the functional clock source is CORE_CLK, its frequency can be divided (by 2, 3, 4, or 6). When the functional clock source is COREX2_CLK, its frequency can be divided (by 3 or 5).

Figure 3-47 shows the clocking scheme in the SGX power domain.

Figure 3-47. SGX Power Domain Clocking Scheme



3.5.3.4.1.4 CORE Power Domain

The CORE power domain has L3- and L4-derived clock domains.

The CORE power domain receives several functional clocks (12-, 48-, 96-MHz, system, and 32-kHz) that feed its peripherals and modules, with following exception:

- The McBSP 1 and McBSP 5 modules can be clocked by CORE_96M_FCLK from the CM or from an external clock, MCBSP_CLKS. The SCM manages the selection between the two sources. For more information about the SCM, see Chapter 13, *System Control Module*.

Figure 3-48 through Figure 3-50 show the clock signals and their relationships in the CORE power domain.

Figure 3-48. CORE Clock Signals: Part 1

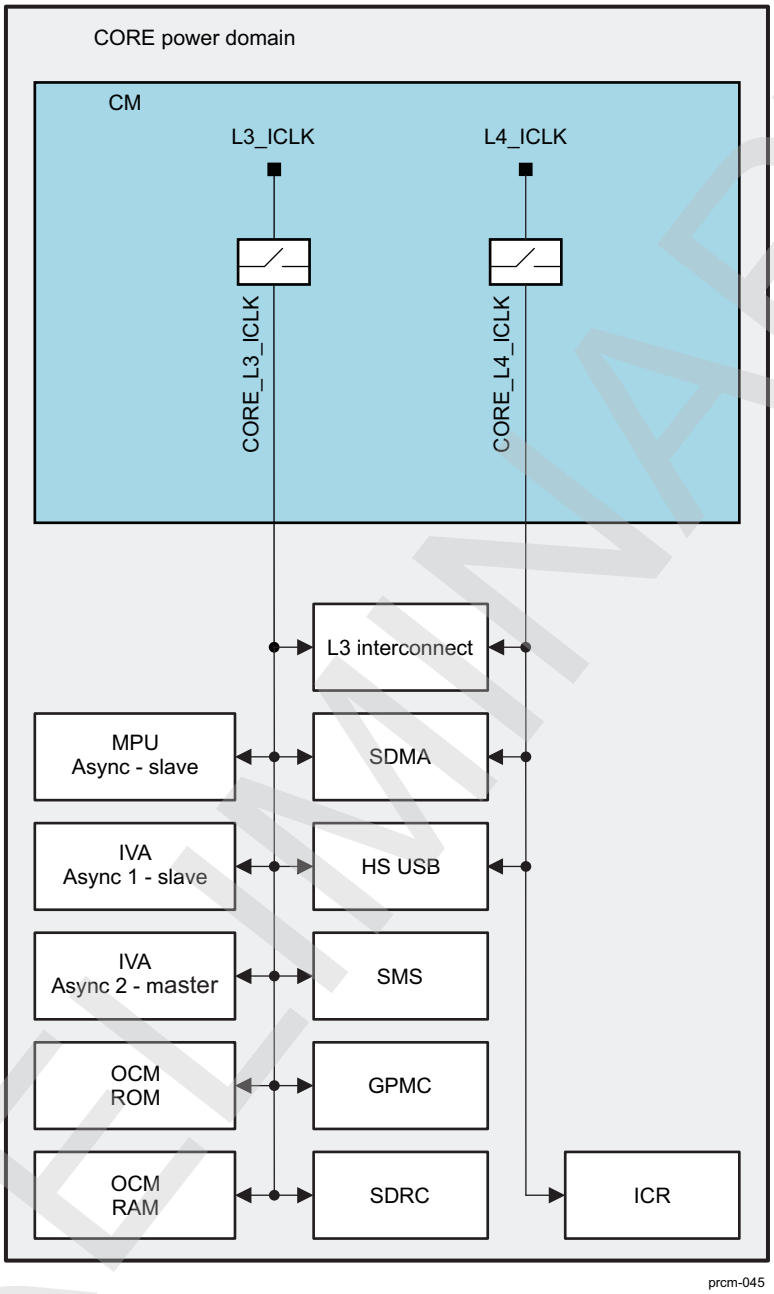


Figure 3-49. CORE Clock Signals: Part 2

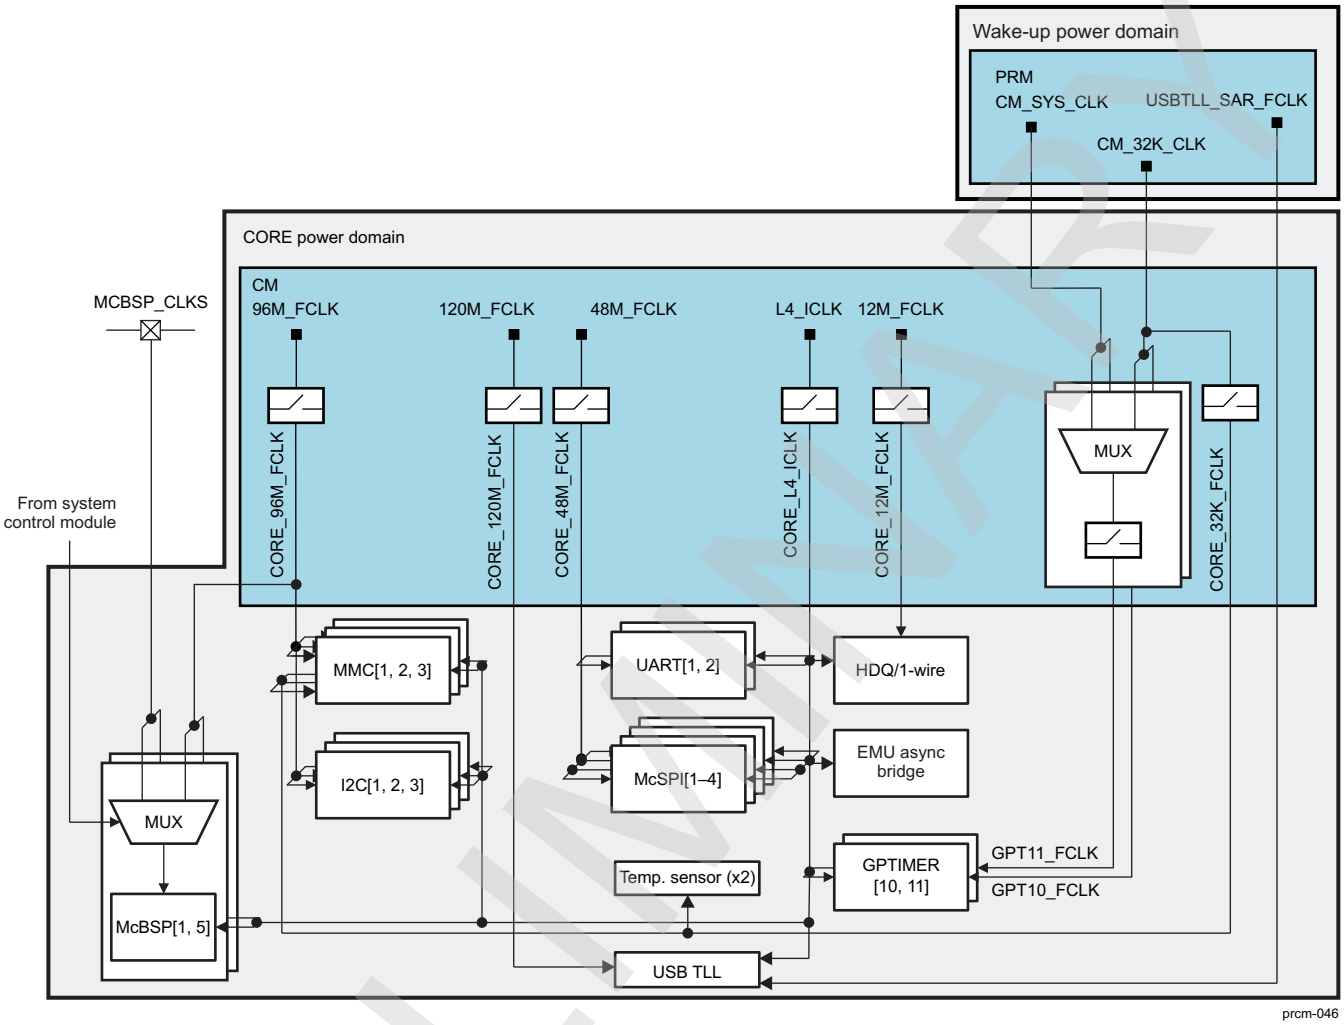

Figure 3-50. CORE Clock Signals: Part 3

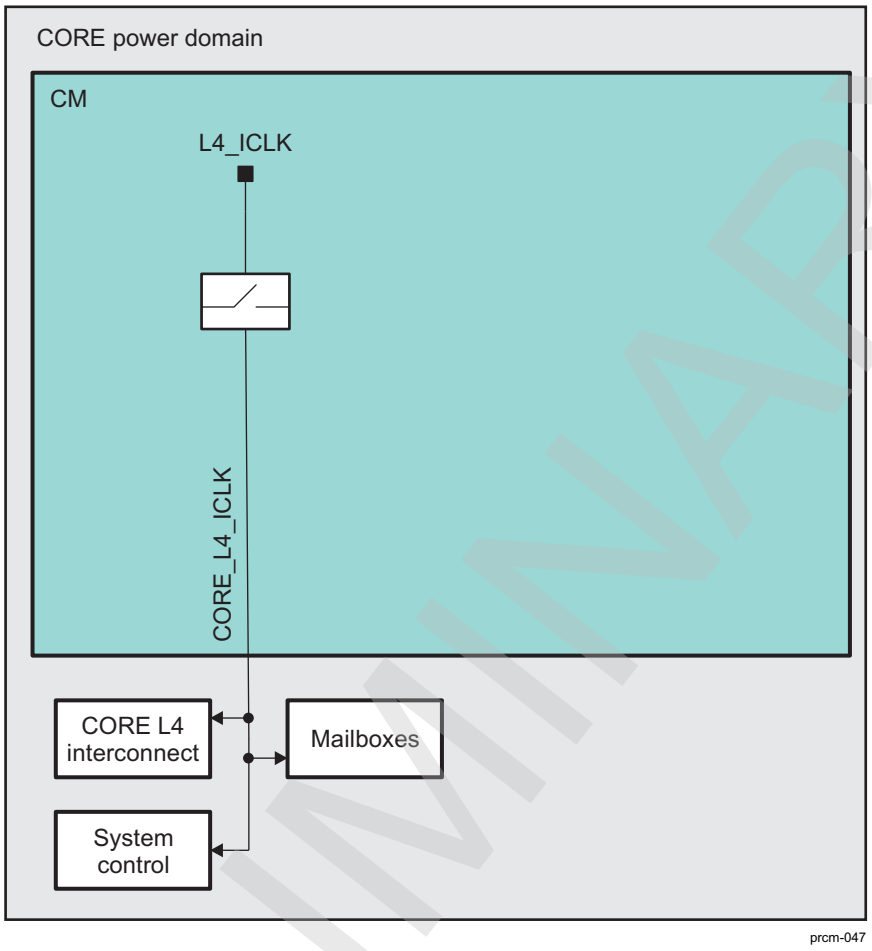
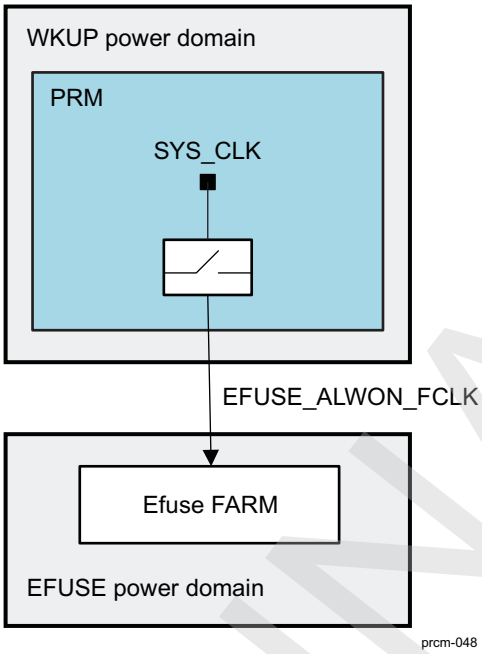


3.5.3.4.1.5 EFUSE Power Domain

Figure 3-51 shows the clock signals and their relationships in the EFUSE power domain.

Figure 3-51. EFUSE Clock Signals



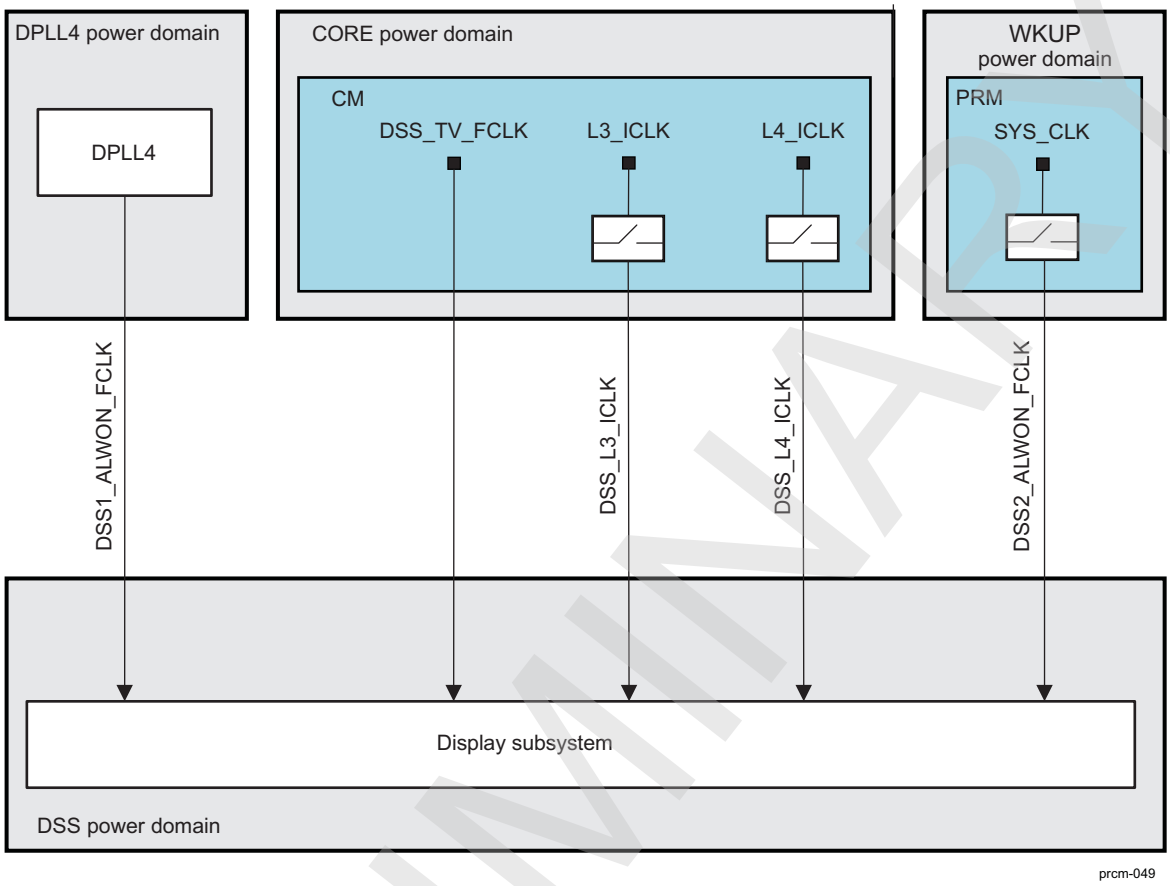
The EFUSE power domain lets the eFuse configuration be saved even when the CORE power domain is off. The EFUSE sense procedure is performed at device power up and on device wakeup from off mode. During this procedure, the PRM enables the EFUSE_ALWON_FCLK clock.

3.5.3.4.1.6 DSS Power Domain

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 3-52 shows the clock signals and their relationships in the DSS power domain.

Figure 3-52. DSS Clock Signals



The DSS subsystem interface is clocked with the L3 and L4 clocks. It receives four functional clocks:

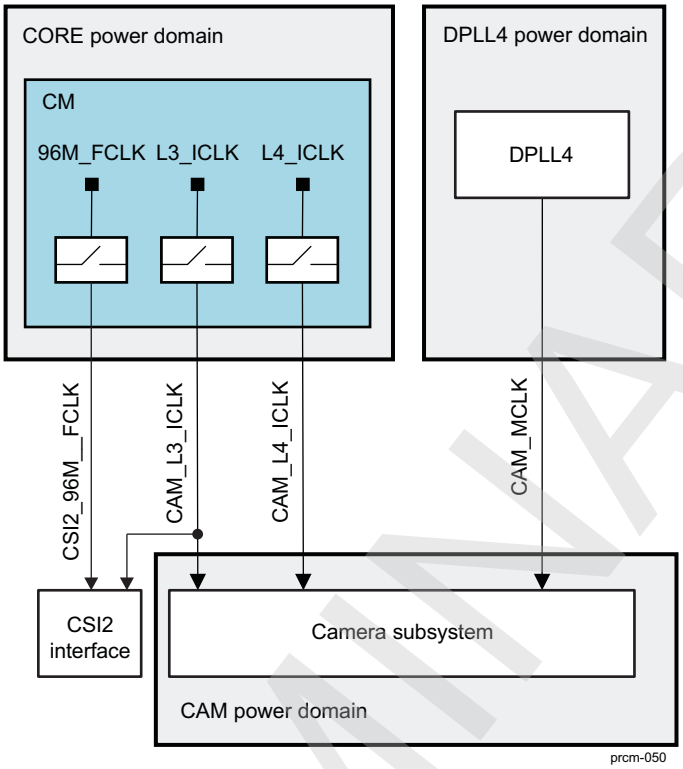
- DSS1_ALWON_FCLK: Issued from DPLL4. Its frequency can be a division by 1 to 16 of the frequency of the DPLL4 synthesized clock.
- DSS2_ALWON_FCLK: The gated SYS_CLK. Used mainly for display in low-power refresh modes.
- DSS_TV_FCLK: Required when TV output is activated

3.5.3.4.1.7 CAM Power Domain

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 3-53 shows the clock signals and their relationships in the CAM power domain.

Figure 3-53. CAM Clock Signals

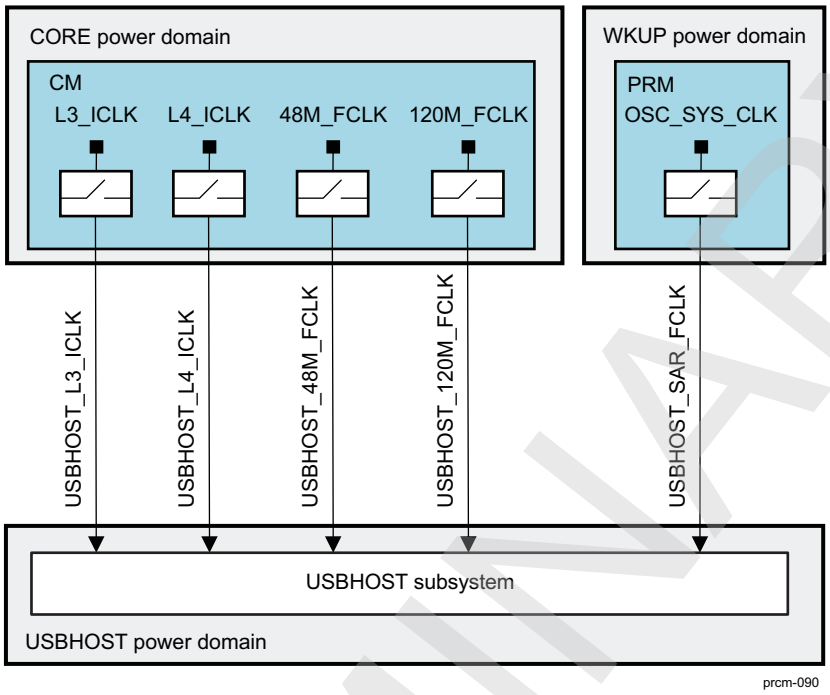


The camera subsystem interface is clocked with the L3 and L4 clocks (CAM_L3_ICLK and CAM_L4_ICLK, respectively). CAM_L3_ICLK is also used as the main functional clock. The functional clock (CAM_MCLK) is provided by DPLL4 to supply the external sensor.

3.5.3.4.1.8 USBHOST Power Domain

Figure 3-54 shows the clock signals and their relationships in the USBHOST power domain.

Figure 3-54. USBHOST Clock Signals



The HS USB host subsystem interface is clocked with the L3 and L4 clocks (USBHOST_L3_ICLK and USBHOST_L4_ICLK, respectively).

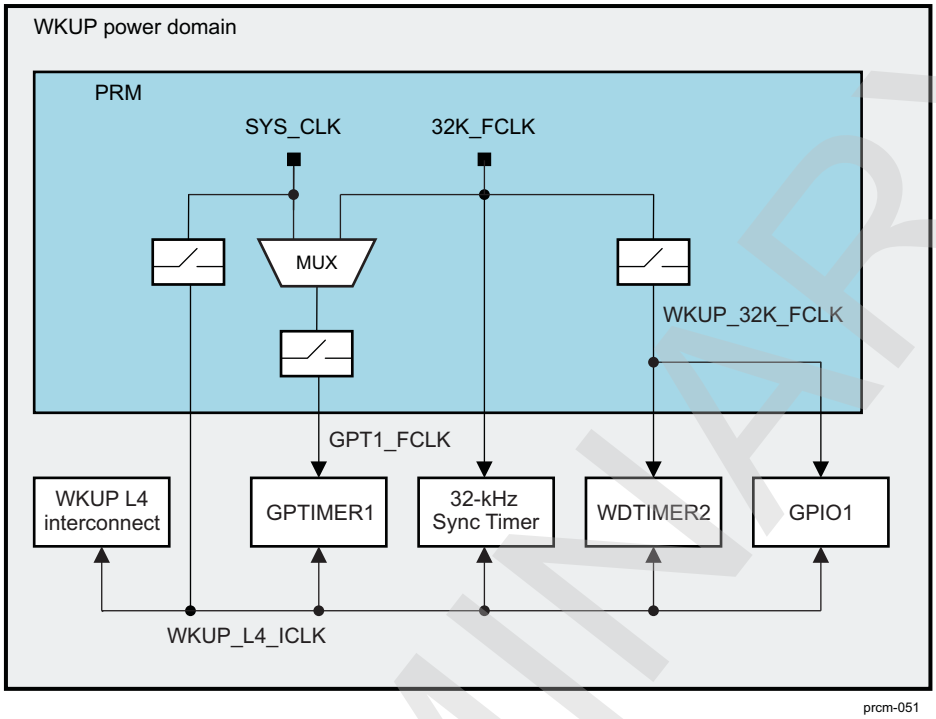
The HS USB host subsystem requires two functional clocks (USBHOST_120M_FCLK and USBHOST_48M_FCLK) that may or may not be requested simultaneously. Therefore, they are gated independently based on the configuration of the CM_FCLKEN_USBHOST[0] EN_USBHOST1 and CM_FCLKEN_USBHOST[1] EN_USBHOST2 bits.

The HS USB host subsystem gets an additional functional clock from the PRM (USBHOST_SAR_FCLK). It is dedicated to the save-and-restore mechanism and is automatically gated/enabled by the PRM, based on the HS USB host save-and-restore bit configuration (the PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit) and on the USBHOST power domain state transitions.

3.5.3.4.1.9 WKUP Power Domain

Figure 3-55 shows the clock signals and their relationships in the WKUP power domain.

Figure 3-55. WKUP Clock Signals



All clocks in the WKUP power domain are generated by the PRM. The functional clock GPT1_FCLK of GPTIMER1 can be selected as SYS_CLK or 32K_FCLK. The 32-kHz sync timer, WDTIMER2, and GPIO1 receive 32K_FCLK as their functional clock. This is the low-frequency always-on clock.

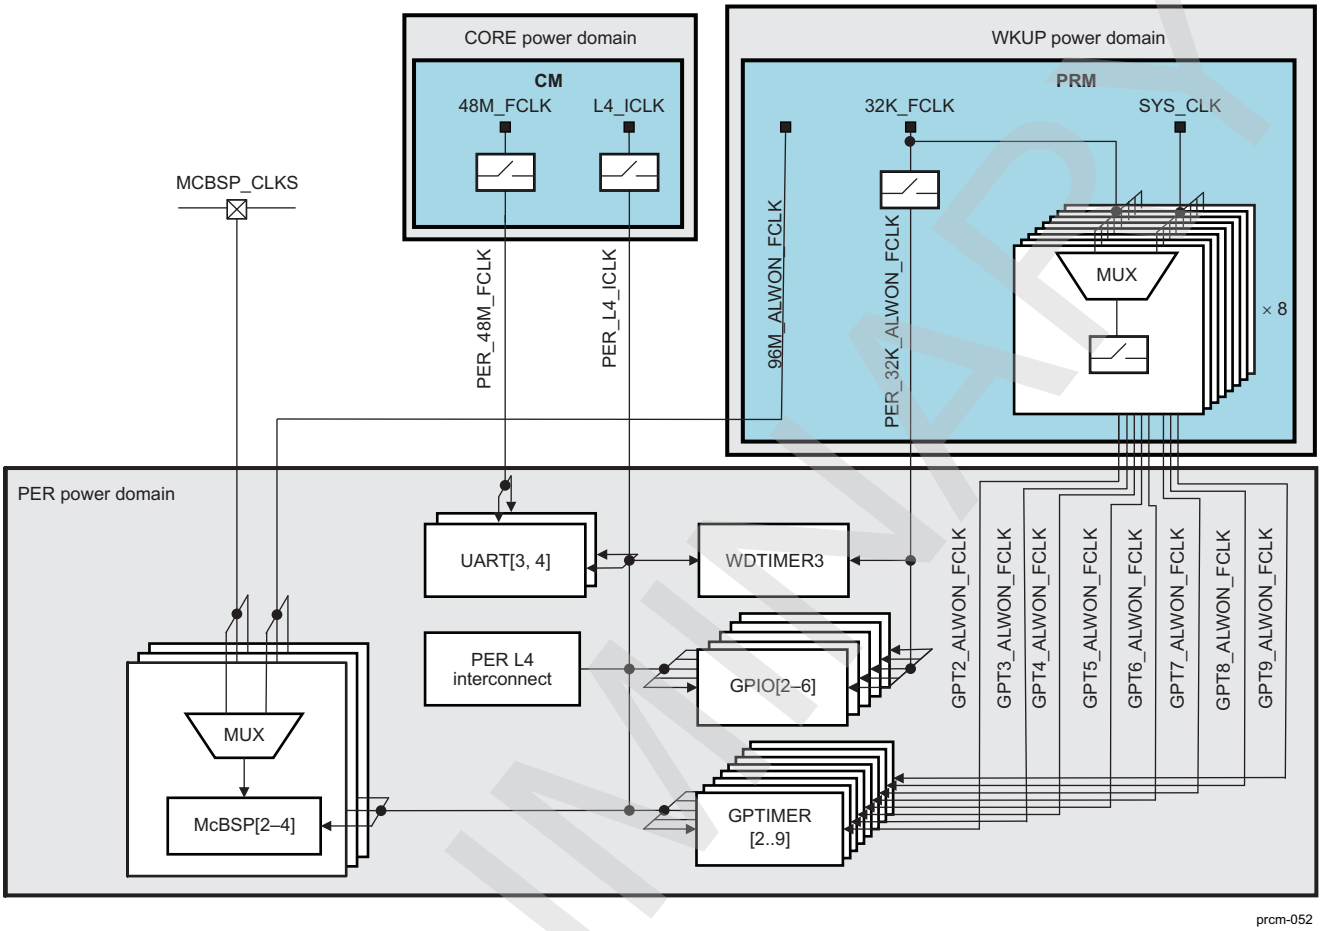
The voltage controller module in the PRM receives SYS_CLK as its functional clock. The dedicated SmartReflex I2C4 module implemented in the voltage controller uses the same functional clock (SYS_CLK).

The PRM receives SYS_CLK as the L4 interface clock. For all other modules of the WKUP power domain, the L4 interface clock WKUP_L4_ICLK is derived from SYS_CLK. Communication between the WKUP power domain and CORE L4 interconnects is asynchronous.

3.5.3.4.1.10 PER Power Domain

Figure 3-56 shows the clock signals and their relationships in the PER power domain.

Figure 3-56. PER Clock Signals



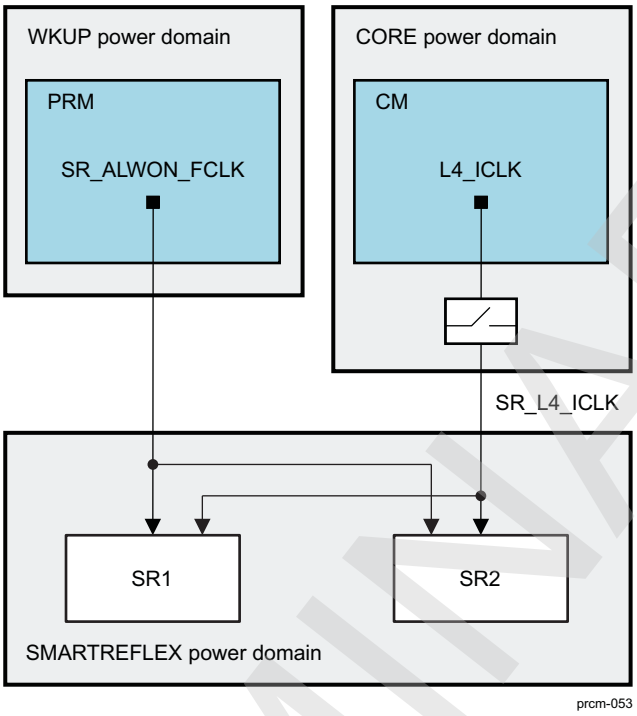
The PER power domain receives several functional clocks (48M_FCLK, 96M_ALWON_FCLK, SYS_CLK, and 32K_FCLK) that feed its peripherals and modules. All the functional clocks (except 48M_FCLK) are permanently supplied so that the peripherals can be used during low-power scenarios, even when the CORE power domain is off. Figure 3-56 shows the clock distribution scheme in the PER power domain.

The McBSP 2, 3, and 4 modules can be clocked by a clock from PRM (PER_96M_FCLK) or from an external clock (MCBSP_CLKS). This clock must be permanently buffered from the pad to the PER power domain. The device SCM manages the selection between the two (see Chapter 13, *System Control Module*).

3.5.3.4.1.11 SMARTREFLEX Power Domain

The two SmartReflex modules in the device have a common L4 interface clock (SR_L4_ICLK) and a functional clock (SR_ALWON_FCLK) (see Figure 3-57).

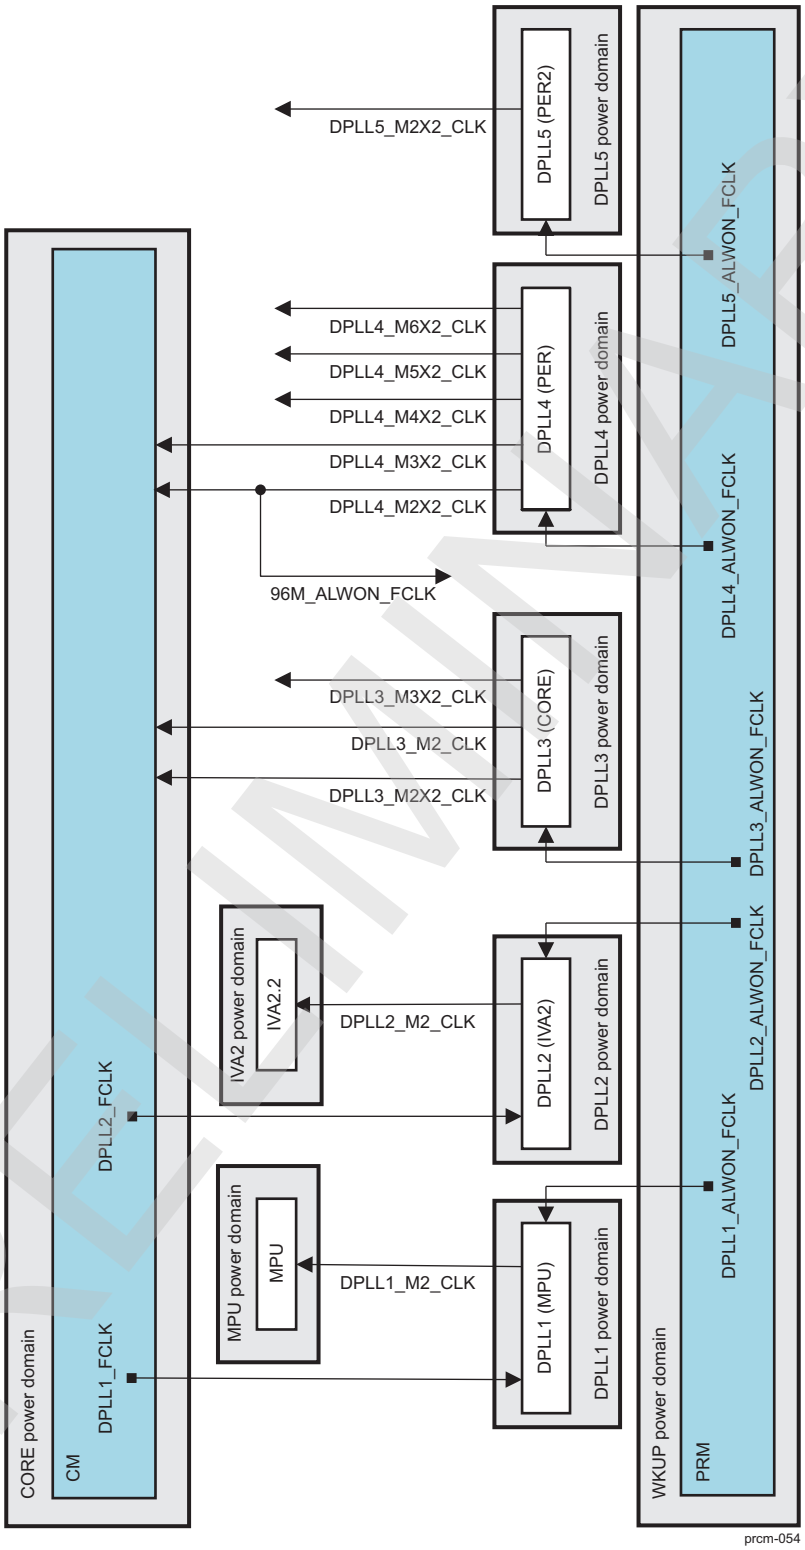
Figure 3-57. SMARTREFLEX Clock Signals



3.5.3.4.1.12 DPLL Domains

The PRCM module provides clock sources for the five DPLLs, as shown in Figure 3-58.

Figure 3-58. DPLL Clock Signals



The PRCM module also manages clock-gating control for these DPLL outputs.

The MPU and IVA2 processors use clock outputs locally in their respective subsystems. The CM uses the DPLL3 clock outputs to generate all interface clocks and some functional clocks. The CM uses two of the five clocks generated by DPLL4 and one clock output of DPLL5 to generate functional clocks for the peripheral domain modules. The remaining three clocks of DPLL4 are propagated to their corresponding modules.

3.5.3.4.2 Clock Distribution Summary

3.5.3.4.2.1 Power Domain Source Clocks

Table 3-33 summarizes clock distribution for each power domain. The clock type indicates whether a clock is supplied when the CM (CORE power domain) is off. "Normal" means that the clock is gated when the power domain is off, while the always-on clock remains active even when the CORE power domain is off.

Table 3-33. Clock Distribution

Power Domain	Clock	Generator	Type	Destination
MPU	MPU_CLK	DPLL1	Normal	MPU subsystem
NEON				NEON
IVA2	IVA2_CLK	DPLL2	Normal	IVA2.2 subsystem
SGX	SGX_FCLK	CM	Normal	SGX subsystem
	SGX_L3_ICLK	CM	Normal	
CORE	CORE_ 120M_FCLK	CM	Normal	USB TLL
	CORE_ 96M_FCLK	CM	Normal	McBSP[1,5], MMC[1,2,3], I2C[1,2,3]
	CORE_48M_FCLK	CM	Normal	UART[1,2], McSPI[1..4]
	CORE_12M_FCLK	CM	Normal	HDQ
	GPT10_FCLK	CM	Normal	GPTIMER10
	GPT11_FCLK	CM	Normal	GPTIMER11
	USBTLL_SAR_FCLK	PRM	Normal	USB TLL
	CM_32K_CLK	PRM	Normal	Temperature sensor (x2), MMC[1,2,3]
	CORE_L3_ICLK	CM	Normal	L3 interconnect, SDMA, MPU async bridge (slave), IVA2 async bridge 1 (slave), IVA2 async bridge 2 (master), HS USB, SMS, GPMC, OCM ROM, SDRC, OCM RAM, CORE L3 interconnect
	CORE_L4_ICLK	CM	Normal	L3 interconnect, SDMA, HS USB, ICR, McBSP[1,5], MMC[1,2], I2C[1..3], GPTIMER [10,11], UART[1,2], McSPI[1..4], HDQ, CORE L4 interconnect, MAILBOXES, SCM
DSS	DSS_TV_FCLK	CM	Normal	DSS, VDAC
	DSS1_ALWON_FCLK	DPLL4	Always-on	DSS
	DSS2_ALWON_FCLK	PRM	Always-on	
	DSS_L3_ICLK	CM	Normal	
	DSS_L4_ICLK	CM	Normal	
CAM	CAM_MCLK	DPLL4	Normal	Camera subsystem
	CAM_L3_ICLK	CM	Normal	Camera subsystem, CSI2 interface
	CAM_L4_ICLK	CM	Normal	Camera subsystem
	CSi2_96M_FCLK	CM	Normal	CSI2 interface
PER	96M_ALWON_FCLK	PRM	Always-on	McBSP[2..4]
	PER_48M_FCLK	CM	Normal	UART[3, 4]
	PER_32K_ALWON_FCLK	CM	Always-on	WDTIMER3, GPIO[2..6],
	GPT2_ALWON_FCLK	PRM	Always-on	GPTIMER2

Table 3-33. Clock Distribution (continued)

Power Domain	Clock	Generator	Type	Destination
	GPT3_ALWON_FCLK	PRM	Always-on	GPTIMER3
	GPT4_ALWON_FCLK	PRM	Always-on	GPTIMER4
	GPT5_ALWON_FCLK	PRM	Always-on	GPTIMER5
	GPT6_ALWON_FCLK	PRM	Always-on	GPTIMER6
	GPT7_ALWON_FCLK	PRM	Always-on	GPTIMER7
	GPT8_ALWON_FCLK	PRM	Always-on	GPTIMER8
	GPT9_ALWON_FCLK	PRM	Always-on	GPTIMER9
	PER_L4_ICLK	CM	Normal	UART[3, 4], PER L4 interconnect, WDTIMER3, GPIO[2..6], GPTIMER[2..9], McBSP[2..4]
WKUP	WKUP_32K_FCLK	PRM	Always-on	WDTIMER2, GPIO1
	32K_FCLK	PRM	Always-on	32-kHz sync timer
	GPT1_FCLK	PRM	Always-on	GPTIMER1
	WKUP_L4_ICLK	PRM	Normal	WKUP L4 interconnect, GPTIMER1, 32-kHz sync timer, GPIO1, WDTIMER2
SMARTREFLEX	SR_ALWON_FCLK	PRM	Always-on	SR1, SR2
	SR_L4_ICLK	CM	Normal	SR1, SR2
EFUSE	EFUSE_ALWON_FCLK	PRM	Always-on	eFuse farm
DPLL1	DPLL1_ALWON_FCLK	PRM	Always-on	DPLL1
	DPLL1_FCLK	CM	Normal	
DPLL2	DPLL2_ALWON_FCLK	PRM	Always-on	DPLL2
	DPLL2_FCLK	CM	Normal	
DPLL3	DPLL3_ALWON_FCLK	PRM	Always-on	DPLL3
DPLL4	DPLL4_ALWON_FCLK	PRM	Always-on	DPLL4
DPLL5	DPLL5_ALWON_FCLK	PRM	Always-on	DPLL5

NOTE:

- Modules supplied by the L3 interface clock only:
  - MPU asynchronous bridge
  - IVA2.2 asynchronous bridges
  - All memory controllers (OCM ROM, OCM RAM, SDRC, SMS, and GPMC)
- Modules that require L3 and L4 clocks:
  - SDMA
  - HS USB
- Modules fed by the L4 clock:
  - SCM
  - Mailboxes
  - ICR
  - Modem INTC
  - All peripherals (McBSP1, McBSP5, MMC1, MMC2, MMC3, I2C1, I2C2, I2C3, McSPI1, McSPI2, McSPI3, McSPI4, UART1, UART2, HDQ, GPTIMER10, GPTIMER11, McBSP2, McBSP3, McBSP4. UART3, UART4, GPIO2, GPIO3, GPIO4, GPIO5, GPIO6, WDT3, GPTIMER2, GPTIMER3, GPTIMER4, GPTIMER5, GPTIMER6, GPTIMER7, GPTIMER8 and GPTIMER9)

NOTE:

- The system clock version provided to the DPLL4 can be pre-divided by a factor of 6.5 before feeding the DPLL4. This is done in the PRM thanks to a dedicated programmable register. This divider is intended to be used in case a 13 MHz system clock is used in order to be able to lock the DPLL4 at 864 MHz.

3.5.3.4.2.2 Peripheral Module Clocks

Table 3-34 lists the peripherals, DSS, and CAM functional clock frequency requirements. These frequencies must be operational over the full VDD2 voltage range.

Table 3-34. Peripheral Module Functional Clock Frequencies

Module	Functional Clock	Frequency
MMC-SDIO[1,2,3]	96M_FCLK	96 MHz
McBSP[1, 5]	96M_FCLK	96 MHz
CAM	CAM_MCLK	Up to 216 MHz
McSPI[1..4]	CORE_48M_FCLK	48 MHz
UART[1..4]		
Display subsystem	DSS1_ALWON_FCLK	Up to 173 MHz
	DSS2_ALWON_FCLK	System clock
	DSS_TV_FCLK	54 MHz
SGX	SGX_FCLK	Up to 200 MHz
I2C[1..3]	CORE_96M_FCLK	96 MHz
HDQ	CORE_12M_FCLK	12 MHz
GPTIMER1	GPT1_FCLK	32-kHz (p) or system clock
GPTIMER[2..9]	GPTn_ALWON_FCLK	32-kHz (p) or system clock
GPTIMER[10, 11]	GPTn_FCLK	32-kHz or system clock
ICR		
WDTIMER2	WKUP_32K_FCLK	32 kHz
WDTIMER3	PER_32K_ALWON_FCLK	32 kHz
GPIO1	WKUP_32K_FCLK	32 kHz
GPIO[2-6]	PER_32K_ALWON_FCLK	32 kHz
32-kHz sync timer	32K_FCLK	32 kHz (p)
Bandgap/temp sensor	32K_FCLK	32 kHz (p)
System control	CORE_L4_ICLK	L4_ICLK

3.5.3.5 External Clock Controls

Because the use of sys_32k and sys_altclk is described in Section 3.5.3.3.1, *PRM*, and Section 3.5.3.3.2, *CM*, these clock signals are not discussed here. This section discusses the remaining external clock signals.

3.5.3.5.1 Clock Request (sys_clkreq) Control

The system clock request signal sys_clkreq is bidirectional.

In bypass mode in the system clock oscillator (see Section 3.5.3.5.2), it is an output signal driven by the device to request an external clock. In this case, the output buffer is driven as long as the system clock is requested by the device; otherwise, it remains in high impedance. In this way, other external peripherals can share the same clock request signal with the device.

If the PRM_POLCTRL[1] CLKREQ_POL bit = 1, the software must configure the SCM to select the internal pulldown on the sys_clkreq pad, or an external pulldown is connected to the pad.

If the PRM_POLCTRL[1] CLKREQ_POL bit = 0, the internal pullup on the sys_clkreq pad, or an external pull-up, is connected to the pad.

In master mode in the system clock oscillator (see Section 3.5.3.5.2), sys_clkreq is an input.

If the PRM_POLCTRL[1] CLKREQ_POL bit = 1, the software must configure the SCM to select the internal pulldown on the sys_clkreq pad, or an external pulldown is connected to the pad.

If the PRM_POLCTRL[1] CLKREQ_POL bit = 0, the internal pullup on the sys_clkreq pad, or an external pullup, is connected to the pad.

The PRCM.PRM_POLCTRL[1] CLKREQ_POL bit allows software control over the polarity of sys_clkreq. This software setting takes effect when the clock is requested by the device, and also when the clock request is driven externally. The output buffer is driven directly by this register when the clock request comes from device.

Table 3-35 describes the bidirectional control of the sys_clkreq pad.

Table 3-35. sys_clkreq Pad Direction Control

Oscillator Mode	Sys_boot 6	Internal Clock Request (Always Active-High)	External Clock Request (Note: polarity depends on CLKREQ_POL)	Sys_clkreq Direction	Description
Master mode	0	0	0(1)	Input (output buffer in Hi-Z) **Note**: Input is not driven from outside of device in this case.	The clock is not requested internally (by the device) or externally (external device/peripheral).
	0	0	1(1)	Input (output buffer in Hi-Z)	The clock is requested externally.
	0	1	0(1)	Output	The clock is requested internally.
	0	1	1(1)	Output **Note**: The pad is driven both by device and from outside of device in this case.	The clock is requested internally and externally.
Bypass mode	1	0	0(1)	Input (output buffer in Hi-Z) **Note**: Input is not driven from outside of device in this case).	The clock is not requested internally or externally.
	1	0	1(1)	Input (output buffer in Hi-Z)	The clock is requested externally.
	1	1	0(1)	Output	The clock is requested internally.
	1	1	1(1)	Output **Note**: The pad is driven by device and from outside of device in this case.	The clock is requested internally and externally.

(1) Case when PRM_POLCTRL.CLKREQ_POL = 1 (sys_clkreq active high). If PRM_POLCTRL.CLKREQ_POL = 0 (sys_clkreq active low), these values should be inverted in Table 3-35.

3.5.3.5.2 System Clock Oscillator Control

Depending on the hardware configuration, the device can receive the system clock from an external source or generate it locally using the internal system clock crystal oscillator. Thus, the device oscillator has two possible operating modes:

- Master (oscillator enable) mode: The oscillator is enabled and connected to an external quartz. It provides the system clock to the device. The oscillator is activated on a device wakeup or on an external clock request. It is set to the power-down (off) state when the device switches to off mode (see Table 3-37), except when the external system clock request is active on sys_clkreq pin.

- Bypass (oscillator inactive) mode: The system clock is supplied by an external device and the oscillator is always set in bypass mode. The oscillator is insensitive to the external system clock request on the sys_clkreq pin.

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the oscillator is in master or bypass mode. See Section 3.3.1, *External Clock Signals*.

When operating in master mode, the device receives an external clock request (sys_clkreq) and provides the oscillator clock (OSC_SYS_CLK) to external peripherals through the sys_clkout1 pin; in bypass mode, the device generates a clock request to the external clock source to request the system clock.

The selected mode of the oscillator can be read from the PRCM.PRM_CLKSRC_CTRL[1:0] SYSCLKSEL bit field.

Regardless of oscillator mode, the oscillator can be powered down when the device enters inactive, retention or off mode, unless an external system clock request is active (from the sys_clkreq pin). This setting is configured in the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field. Table 3-37 lists the four possible operation modes of the system clock.

Table 3-36. System Clock Operation Modes

AUTOEXTCLKMODE	System Clock Mode	Oscillator Mode	Description
0x0	Always-active mode	Master	The oscillator is kept active even when the clock is not requested by the device internally (all device clocks are inactive) or externally (the sysclkreq input signal is not asserted).
		Bypass	The sys_clkreq output signal is permanently asserted by the device, regardless of its internal clock states (active or inactive).
0x1	Off when device in inactive, retention, or off state	Master	The oscillator is switched to off mode when the device is in inactive, retention, or off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is deasserted when the device is in idle, retention, or off mode.
0x2	Off when device in retention or off state	Master	The oscillator is switched to off mode when the device is in retention or off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is deasserted when the device is in retention or off mode.
0x3	Off when device in off state	Master	The oscillator is switched to off mode when the device is in off mode and the sys_clkreq input signal is not asserted.
		Bypass	The sys_clkreq output signal is deasserted when the device is in off mode.

To exit power-down mode, the oscillator requires a device wakeup or an external clock request.

The device allows configuring of the system clock stabalization time to ensure a stable system clock in the device. This delay is configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

Figure 3-59 shows the system clock oscillator controls in the device.

Figure 3-59. System Clock Oscillator Controls

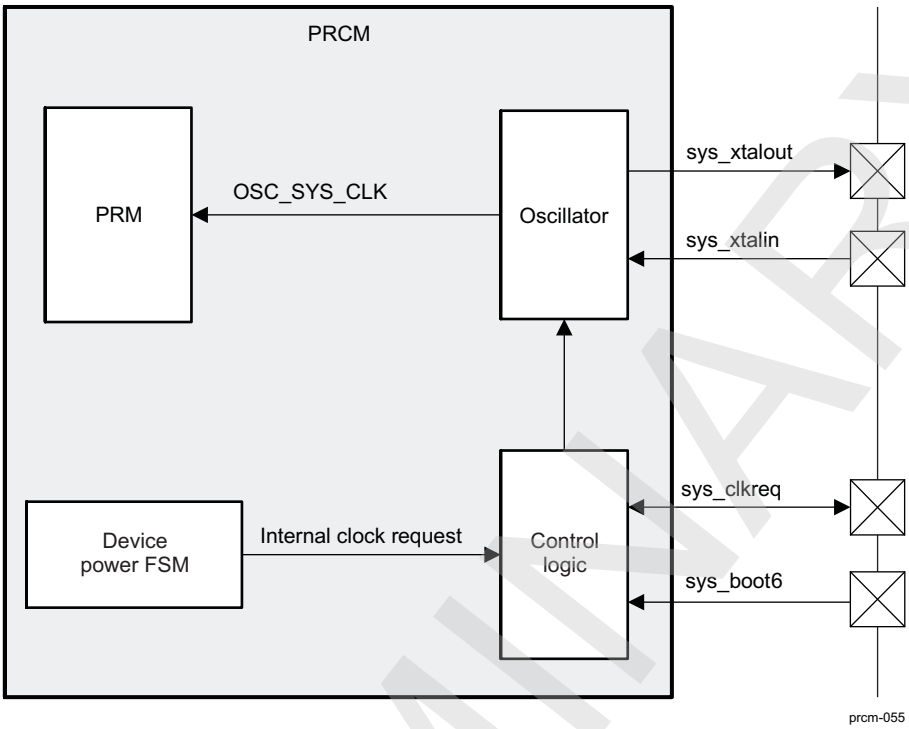


Table 3-37 lists the oscillator controls.

Table 3-37. Oscillator Controls

Oscillator Mode	Internal Clock Request [1]	External Clock Request [1]	Oscillator State	sys_clkreq Pad Direction	sys_clkreq [1]	Description
Master	Not asserted	Not asserted	Off	Input and output	Not asserted	System clock not requested internally (within the device) or externally (by an external device or peripheral)
	Not asserted	Asserted	Active	Input	Asserted	System clock is requested externally only.
	Asserted	Not asserted	Active	Output	Asserted	System clock is requested internally only.
	Asserted	Asserted	Active	Input and output (driven internally by device and externally by peripheral)	Asserted	System clock is requested internally and externally.
Bypass	Not asserted	x[2]	Bypass	Input and output (when external request is not asserted) or input (when external request is asserted)	External clock request state	System clock is not requested internally (sys_clkreq input has no effect).
	Asserted	x[2]	Bypass	Output (when only internal request is asserted) or input and output (when external and internal request are asserted)	Asserted	System clock is requested internally (sys_clkreq input has no effect).

(1)
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active high (0x1), Asserted = 1, and Not asserted = 0.
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active low (0x0), Asserted = 0, and Not asserted = 1.

(2) x indicates that the signal may be asserted or not asserted.

3.5.3.5.3 External Output Clock1 (sys_clkout1) Control

The sys_clkout1 clock is active if the oscillator clock (OSC_SYS_CLK) is active (stable) and an external system clock request is active. It can be gated by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit. The polarity of the sys_clkout1 signal, when the clock is gated, is controllable by programming the PRCM.PRM_POLCTRL[2] CLKOUT_POL bit.

When the device is in standby mode, SYS_CLK and sys_clkout1 are disabled. in this case, reactivation of sys_clkout1 depends on the oscillator mode:

- Oscillator in active mode (sys_boot6 is 0): The sys_clkout1 clock can be reactivated (after oscillator stabilization), provided its gating was enabled by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit and asserting an external clock request. This activation does not generate a device wake-up event; an external clock request activates only the internal SYS_CLK oscillator and sys_clkout1.
- Oscillator in bypass mode (sys_boot6 is 1): The sys_clkout1 clock can be reactivated only after the device wakes up (on any wake-up event) and SYS_CLK is active. When the device is active, SYS_CLK is running and sys_clkout1 is enabled as soon as requested by software.

3.5.3.5.4 External Output Clock2 (sys_clkout2) Control

A second output clock, sys_clkout2, is generated with a frequency that can be the source-clock frequency divided by 1, 2, 4, 8, or 16. Its source clock can be CORE_CLK, CM_SYS_CLK, 96 MHz, or 54 MHz. Unlike sys_clkout1, this second external clock is not active when the device is in off power mode. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock. The polarity of the sys_clkout2 signal, when the clock is gated, is controllable by programming the PRCM.CM_POLCTRL[0] CLKOUT2_POL bit.

3.5.3.6 DPLL Control

The PRCM module allows the configuration of the output clock frequencies of the DPLLs by setting their multipliers and dividers. It also allows control of the operating mode of the DPLLs and automatic recalibration mode.

3.5.3.6.1 DPLL Multiplier and Divider Factors

DPLL clock outputs are set by programming the corresponding multiplier and divider factors M, N, M2, M3, M4, M5, and M6. Table 3-38 lists the register bit fields for configuration of the multiplier and divider factors for the DPLLs.

Table 3-38. DPLL Multiplier and Divider Factors

	DPLL1	DPLL2	DPLL3	DPLL4	DPLL5
M	PRCM.CM_CLKSEL1_ PLL_MPU[18:8] MPU_ DPLL_MULT	PRCM. CM_CLKSEL1_PLL_ IVA2[18:8] IVA2_ DPLL_MULT	PRCM.CM_CLKSEL1_ PLL[26:16] CORE_DPLL_MULT	PRCM.CM_CLKSEL2_ PLL[18:8] PERIPH_ DPLL_MULT	PRCM.CM_CLKSEL4_ PLL[18:8] PERIPH2_ DPLL_MULT
N	PRCM.CM_CLKSEL1_ PLL_MPU[6:0] MPU_ DPLL_DIV	PRCM. CM_CLKSEL1_PLL_ IVA2[6:0] IVA2_DPLL_DIV	PRCM.CM_CLKSEL1_ PLL[14:8] CORE_DPLL_DIV	PRCM.CM_CLKSEL2_ PLL[6:0] PERIPH_ DPLL_DIV	PRCM.CM_CLKSEL4_ PLL[6:0] PERIPH2_ DPLL_DIV
M2	PRCM.CM_CLKSEL2_ PLL_MPU[4:0] MPU_ DPLL_CLKOUT_DIV	PRCM. CM_CLKSEL2_PLL_ IVA2[4:0] IVA2_DPLL_ CLKOUT_DIV	PRCM.CM_CLKSEL1_ PLL[31:27] CORE_DPLL_ CLKOUT_DIV	PRCM.CM_CLKSEL3_ PLL[4:0] DIV_96M	PRCM.CM_CLKSEL5_ PLL[4:0] DIV_120M
M3	Not used	Not used	PRCM.CM_CLKSEL1_ EMU[21:16] DIV_DPLL3	PRCM.CM_CLKSEL_ DSS[13:8] CLKSEL_TV	Not used
M4	Not used	Not used	Not used	PRCM.CM_CLKSEL_ DSS[5:0] CLKSEL_DSS1	Not used
M5	Not used	Not used	Not used	PRCM.CM_CLKSEL_ CAM[5:0] CLKSEL_CAM	Not used
M6	Not used	Not used	Not used	PRCM.CM_CLKSEL1_ EMU[29:24] DIV_DPLL4	Not used

3.5.3.6.2 DPLL Modes

DPLL supports several power modes (see Table 3-39). Each mode results in a tradeoff between power savings and relock time.

Table 3-39. DPLL Power Modes

Mode	Clock Input	Clock Output	DPLL Power State	Power Consumption	Latency
Locked	On	Lock frequency	ON	Maximum	N/A
Low-power bypass	On	Bypass frequency	ON	Less than locked	Same as low-power stop
Fast-relock bypass	On	Bypass frequency	ON	Less than locked	Less than low-power bypass
Low-power stop	On	Bypass frequency	ON	Less than locked	Same as low-power bypass
MN bypass	On	Bypass frequency	ON	Less than locked	Maximum
Off	Off	Off	Off	Minimum	Maximum

A DPLL power mode can be achieved on a software request (manual) and/or automatically (automatic), depending on the specific hardware conditions. After a device power-on reset, the DPLL can be kept in low-power stop mode (DPLL2 , DPLL4, and DPLL5) or MN bypass mode (DPLL1 and DPLL3).

A DPLL can switch from one mode to the other as a result of the following:

- Software-programmed transition only (manual): The software configures a dedicated register for the next desired DPLL mode. It must ensure that the transition can be performed based on the activity on the device.
- Combined software-programmed and hardware-conditions-based transition (automatic): The PRCM module triggers the transition when the software requests it (by configuring the registers) and the hardware conditions are satisfied. When the hardware conditions are no longer met, the PRCM module triggers the return transition.

For automatic transition, automatic mode must be enabled by programming the PRCM.CM_AUTOIDLE_PLL or the PRCM.CM_AUTOIDLE_PLL_<processor_name> registers.

Table 3-40 describes the manual and automatic control of the DPLL power modes by the PRCM module.

Table 3-40. DPLL Power Mode Support

Mode	DPLL1	DPLL2	DPLL3	DPLL4	DPLL5
Locked	Software request (manual) or MPU wakes up (automatic).	Software request (manual) or IVA2.2 wakes up (automatic).	Software request (manual) or CORE wakes up (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).	Software request (manual) or at least one peripheral clock is used (automatic).
Low-power bypass	Software request (manual)	Software request (manual)	Software request (manual) or all interface clocks are gated (automatic).	N/A	N/A
Fast-relock bypass	N/A	N/A	Software request (manual)	N/A	N/A
Low-power stop	MPU is idle (automatic).	Software request (manual) or IVA2.2 is idle (automatic) or on global reset release (automatic).	Device is idle (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL are unused or on global reset release (automatic).	(Default state) Software request (manual) or all functional clocks from DPLL (120-MHz clock) are unused or on global reset release (automatic).
MN bypass	Global reset (automatic)	N/A	Global reset (automatic)	N/A	N/A
Off	Device off (automatic)	Device off (automatic)	Device off (automatic)	Device off (automatic)	Device off (automatic)

NOTE: DPLL1 and DPLL3 cannot be manually forced to switch to Low-Power Stop mode from any other power mode. They must be in Locked state with automatic transition to Low-Power Stop mode configured and the hardware condition for the transition (identified in Table 3-40) must be satisfied, in order to switch to the Low-Power Stop mode.

Table 3-41 lists the bit fields that must be programmed for manual and automatic mode control of the five DPLLs.

Table 3-41. DPLL Power Mode Control

Mode	Manual Control	Auto Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL
DPLL2	PRCM.CM_CLKEN_PLL_IVA2[2:0] EN_IVA2_DPLL	PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL
DPLL3	PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL
DPLL4	PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL
DPLL5	PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL

NOTE: The DPLL automatically enters locked mode on a power domain wakeup only if the DPLL is locked before the sleep transition and one of the automatic modes is enabled.

3.5.3.6.3 DPLL Low-Power Mode

The DPLL can operate in a low-power mode by reducing the operating frequency range. This reduces the power consumption of the DPLL. In this mode, however, there is a period and phase jitter effect.

The DPLL can enter this mode only if the targeted lock frequency of the DPLL is less than 600 MHz. This implies locking or relocking the DPLL to a new targeted locked-frequency when entering or exiting low-power mode. Software must ensure that the DPLL lock frequency does not exceed 600 MHz in low-power mode.

Software can enable/disable automatic switching of the DPLL between normal mode and low-power mode. The new mode is effective only after the DPLL is relocked. Low-power mode control is considered only during the following transitions:

- Bypass mode to lock
- Stop mode to lock
- Lock to relock

Table 3-42 lists the bit fields that must be programmed for manual control of the five DPLLs.

Table 3-42. LP Mode Control

Mode	Manual Control
DPLL1	PRCM.CM_CLKEN_PLL_MPU[10] EN_MPU_DPLL_LPMODE
DPLL2	PRCM.CM_CLKEN_PLL_IVA2[10] EN_IVA2_DPLL_LPMODE
DPLL3	PRCM.CM_CLKEN_PLL[10] EN_CORE_DPLL_LPMODE
DPLL4	PRCM.CM_CLKEN_PLL[26] EN_PERIPH_DPLL_LPMODE
DPLL5	PRCM.CM_CLKEN2_PLL[10] EN_PERIPH2_DPLL_LPMODE

3.5.3.6.4 DPLL Clock Path Power Down

DPLL3 and DPLL4 can power down the CLKOUTX2 path. A small section of logic is powered down, because the M2 post divider is shared with the CLKOUT path, which remains functional.

The HSDIVIDER can power down each CLKOUTn path (with n in the range of 3 to 6) independently, therefore allowing further power savings. The clock output path is also powered down when the DPLL is in stop mode, regardless of the software setting.

Software must ensure correct sequencing of the control. To avoid a glitch at the output, activate this control when the clock is not required, and when the output clock is gated. Conversely, ensure a delay between deactivation and reactivation of the clock by using the power-down control.

Table 3-43 lists the bit fields and the corresponding clock outputs of the DPLLs.

Table 3-43. Clock Path Power-Down Control

DPLL	Control Bit Field	Clock Path
DPLL4	PRCM.CM_CLKEN_PLL[27] PWRDN_96M	96-MHz clock output (DPLL4 output M2)
	PRCM.CM_CLKEN_PLL[28] PWRDN_TV	DSS TV clock output (DPLL4 output M3)
	PRCM.CM_CLKEN_PLL[29] PWRDN_DSS1	DSS1 clock output (DPLL4 output M4)
	PRCM.CM_CLKEN_PLL[30] PWRDN_CAM	CAM clock output (DPLL4 output M5)
	PRCM.CM_CLKEN_PLL[31] PWRDN_EMU_PERIPH	EMU_PERIPH clock output (DPLL4 output M6)
DPLL3	PRCM.CM_CLKEN_PLL[12] PWRDN_EMU_CORE	EMU_CORE clock output (DPLL3 output M3X2)

3.5.3.6.5 Recalibration

A lock sequence occurs during an initial lock or during a relock following a new multiplier or divider value. Each time the DPLL is reset or performs a lock sequence, it performs a recalibration of the output frequency, based on voltage and temperature conditions. By compensating for voltage and temperature changes within a certain range, calibration allows the lock frequency to remain steady. If the voltage or temperature drifts outside the acceptable range, the DPLL asserts a recalibration flag.

For example, a large temperature drift can cause the DPLL to lose its lock and require recalibration. When the DPLL locks at a temperature within the 080 degrees Celsius range, the maximum temperature drift is approximately 55 degrees Celsius. When DPLL starts at a negative temperature, the maximum temperature drift is higher.

If the DPLL locks at 30 degrees Celsius, the temperature can change by 60 degrees Celsius (from 30 to +90 degrees Celsius) and the DPLL does not lose the lock. However, for temperatures above the 60 degrees Celsius range, the DPLL may need to be relocked. A new relock sequence reinitializes the starting temperature.

This compensation mechanism is active only while the DPLL is locked. When the DPLL is in off or bypass mode (low-power or fast-relock), it does not assert the recalibration flag. If the voltage or temperature exceeds the drift limits while the DPLL is not locked, and then the DPLL tries to relock, the DPLL fails to lock within the normal delay and recalibrates automatically before eventually locking. The only difference from a standard relock is the delay.

The DPLL can automatically start recalibration when the recalibration flag is asserted, or recalibration can be managed by the software. The mode of operation is selected by configuring the corresponding registers in the PRCM module (see Table 3-44). The software or manual control mode is selected by default.

NOTE: Automatic recalibration of the DPLL can start at any time. While relocking, the DPLL switches to bypass mode. For modules that are sensitive to frequency change while operating, this can introduce operational instability. For example, the SDRC is sensitive to a frequency change on DPLL3 because its embedded DLL relocks on a frequency change. Any access during this DLL relock period can be corrupted. It is important; therefore, to stall SDRC access during DPLL recalibration.

To let the software recalibrate the DPLL at the correct time depending on the device activity, the PRCM module can generate a wake-up event on the MPU power domain, followed by an interrupt on the MPU when the DPLL recalibration flag is asserted.

Table 3-44 summarizes software programming control over the DPLL recalibration feature.

Table 3-44. DPLL Recalibration Controls

DPLL	Software Control	Description
DPLL1 (MPU)	PRCM.CM_CLKEN_PLL_MPU[3] MPU_DPLL_DRIFTGUARD	Enable/disable the MPU DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN	Enable/disable the MPU DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST	Status of the MPU DPLL recalibration interrupt
DPLL2 (IVA2)	PRCM.CM_CLKEN_PLL_IVA2[3] IVA2_DPLL_DRIFTGUARD	Enable/disable the IVA2 DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[8] IVA2_DPLL_RECAL_EN	Enable/disable the IVA2 DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[8] IVA2_DPLL_ST	Status of the IVA2 DPLL recalibration interrupt to MPU
	PRCM.PRM_IRQENABLE_IVA2[2] IVA2_DPLL_RECAL_EN	Enable/disable the IVA2 DPLL recalibration interrupt to IVA2.2.
	PRCM.PRM_IRQSTATUS_IVA2[2] IVA2_DPLL_ST	Status of the IVA2 DPLL recalibration interrupt to IVA2.2
DPLL3 (CORE)	PRCM.CM_CLKEN_PLL[3] EN_CORE_DPLL_DRIFTGUARD	Enable/disable the CORE DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL	Enable/disable the CORE DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST	Status of the CORE DPLL recalibration interrupt
DPLL4 (PER)	PRCM.CM_CLKEN_PLL[19] EN_PERIPH_DPLL_DRIFTGUARD	Enable/disable the PER DPLL automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL	Enable/disable the PER DPLL recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST	Status of the PER DPLL recalibration interrupt
DPLL5 (PER2)	PRCM.CM_CLKEN2_PLL[3] EN_PERIPH2_DPLL_DRIFTGUARD	Enable/disable the PER DPLL2 automatic recalibration feature.
	PRCM.PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN	Enable/disable the PER DPLL2 recalibration interrupt to MPU.
	PRCM.PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_ST	Status of the PER DPLL2 recalibration interrupt

NOTE: DPLL recalibration is not necessary in real use (specified operating voltage and temperature range).

3.5.3.6.6 DPLL Programming Sequence

The DPLL programming sequence follows:

1. Set the M and N values for the desired CLKOUT frequency (see Section 3.5.3.6.1).
2. Set the corresponding output dividers (M2, M3, M4, M5, and M6) (see Section 3.5.3.6.1).
3. Enable/disable the autorecalibration feature (see Section 3.5.3.6.5).
4. Enable/disable the autoidle feature (see Section 3.5.3.6.2).
5. Mask/unmask the interrupt to the MPU (and the DPLL2 interrupt to IVA2) (see Section 3.5.3.6.5).
6. Enable the DPLL lock mode (see Section 3.5.3.6.2).

3.5.3.7 Internal Clock Controls

This section describes the software and hardware controls of the internal source clocks. Figure 3-60 through Figure 3-74 list the clock controls. The Source selection/division column lists the PRCM register bits that select or divide the clocks. The Software control column lists the PRCM register bits that enable/disable the clocks. The Hardware control column lists the hardware conditions required to effectively gate the clocks.

In the Hardware control column, the boxes labeled CL, GS, GC, and HC indicate specific information about the hardware clock controls:

- CL (combinational logic): The functional or interface clock is required by more than one module across more than one power domain. The gating control is the OR combination of all the domain clock requests. If any module of this clock domain requests the clock, the clock is not gated.
- GS (gating selection): The clock is selectable among several possible source clocks for a module. The gating control depends on the software programming of the CM_CLKSEL_<domain_name> type of register. The clock request of the module or domain must be set by the CM_CLKSEL bit.
- GC (gating control): The functional/interface clock is required by a single module across the power domain. The gating control depends only on the software programming of the FCLKEN/ICLKEN bit. For the interface clock, the enable bit is effective only if autoidle mode is not used. If autoidle mode is used, the gating control also depends on the state of the power domain.
- HC (hardware control): A specific rule not covered by CL, GS, or GC.

NOTE: Because the PRCM module must receive hardware acknowledgement from the different modules before it can gate the clock, the clock is not gated immediately after the software requests clock-gating conditions.

3.5.3.7.1 PRM Source-Clock Controls

Figure 3-60 shows the common source-clock controls for the PRM.

Figure 3-60. Common PRM Source-Clock Controls

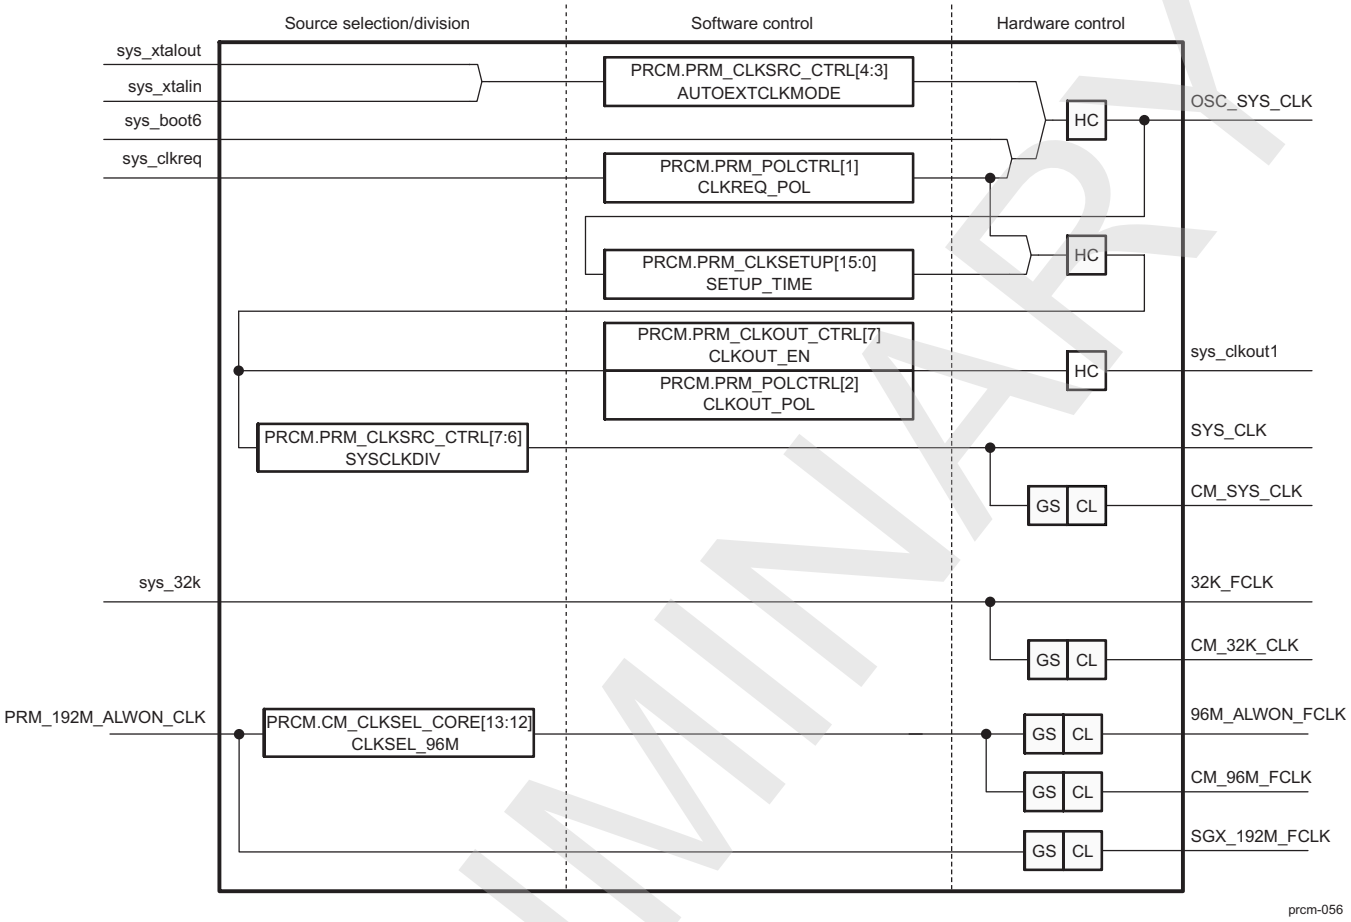

Table 3-45 shows the common source-clock gating controls for the PRM.

Table 3-45. Common PRM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
OSC_SYS_CLK	Running	PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE and device power state and sys_clkreq	Gated when the oscillator is programmed to power down with the device sleep/retention/off transition
sys_clkout1	Running	PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN and PRCM.PRM_POLCTRL[2] CLKOUT_POL and sys_clkreq	Active when OSC_SYS_CLK is active, sys_clkout1 is enabled, and sys_clkreq is asserted
SYS_CLK	Running	Activated after clksetup_count_overflow	Active when OSC_SYS_CLK is active and the SYS_CLK setup time is up
CM_SYS_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active
32K_FCLK	Running	None	Always-active clock from the sys_32k input pin
CM_32K_CLK	Running	PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK	Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active
CM_96M_FCLK	Gated	CM_CLKSEL1_PLL[3] SOURCE_48M bit cleared, and depends on the clock-gating condition of 96M_FCLK, 48M_FCLK, and 12M_FCLK	Active if the derived clocks (96M_FCLK, 48M_FCLK, and 12M_FCLK) are active or when SGX has its functional clock enable and its source is the 96MHz clock

Table 3-45. Common PRM Source-Clock Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
96M_ALWON_FCLK	Gated	CM_FCLKEN_PER[0] EN_MCBSP2, CM_FCLKEN_PER[1] EN_MCBSP3, CM_FCLKEN_PER[2] EN_MCBSP4, CM_FCLKEN_SGX[1] EN_SGX	Gated when none of the three McBSPs [2..4] have their functional clock enable requested
SGX_192M_FCLK	Gated	CM_FCLKEN_SGX[1] EN_SGX	Active when SGX has its functional clock enabled and its source is the 192MHz clock

The oscillator output clock (OSC_SYS_CLK) is gated when the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field is programmed to power down the oscillator when the device enters retention or off mode. In this condition, all the clock trees in the device must be gated, and the four DPLLs (DPLL1, DPLL2, DPLL3, and DPLL4) must enter stop mode before this transition can occur.

SYS_CLK is gated under the same conditions as the oscillator output clock, but it is enabled only after the oscillator stabilizes. Oscillator stabilization is determined by a counter overflow configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

The sys_clkreq active condition is described in Section 3.5.3.5, *External Clock Control*.

3.5.3.7.2 CM Source-Clock Controls

Figure 3-61 shows the common source-clock controls for the CM.

Figure 3-61. Common CM Source-Clock Controls

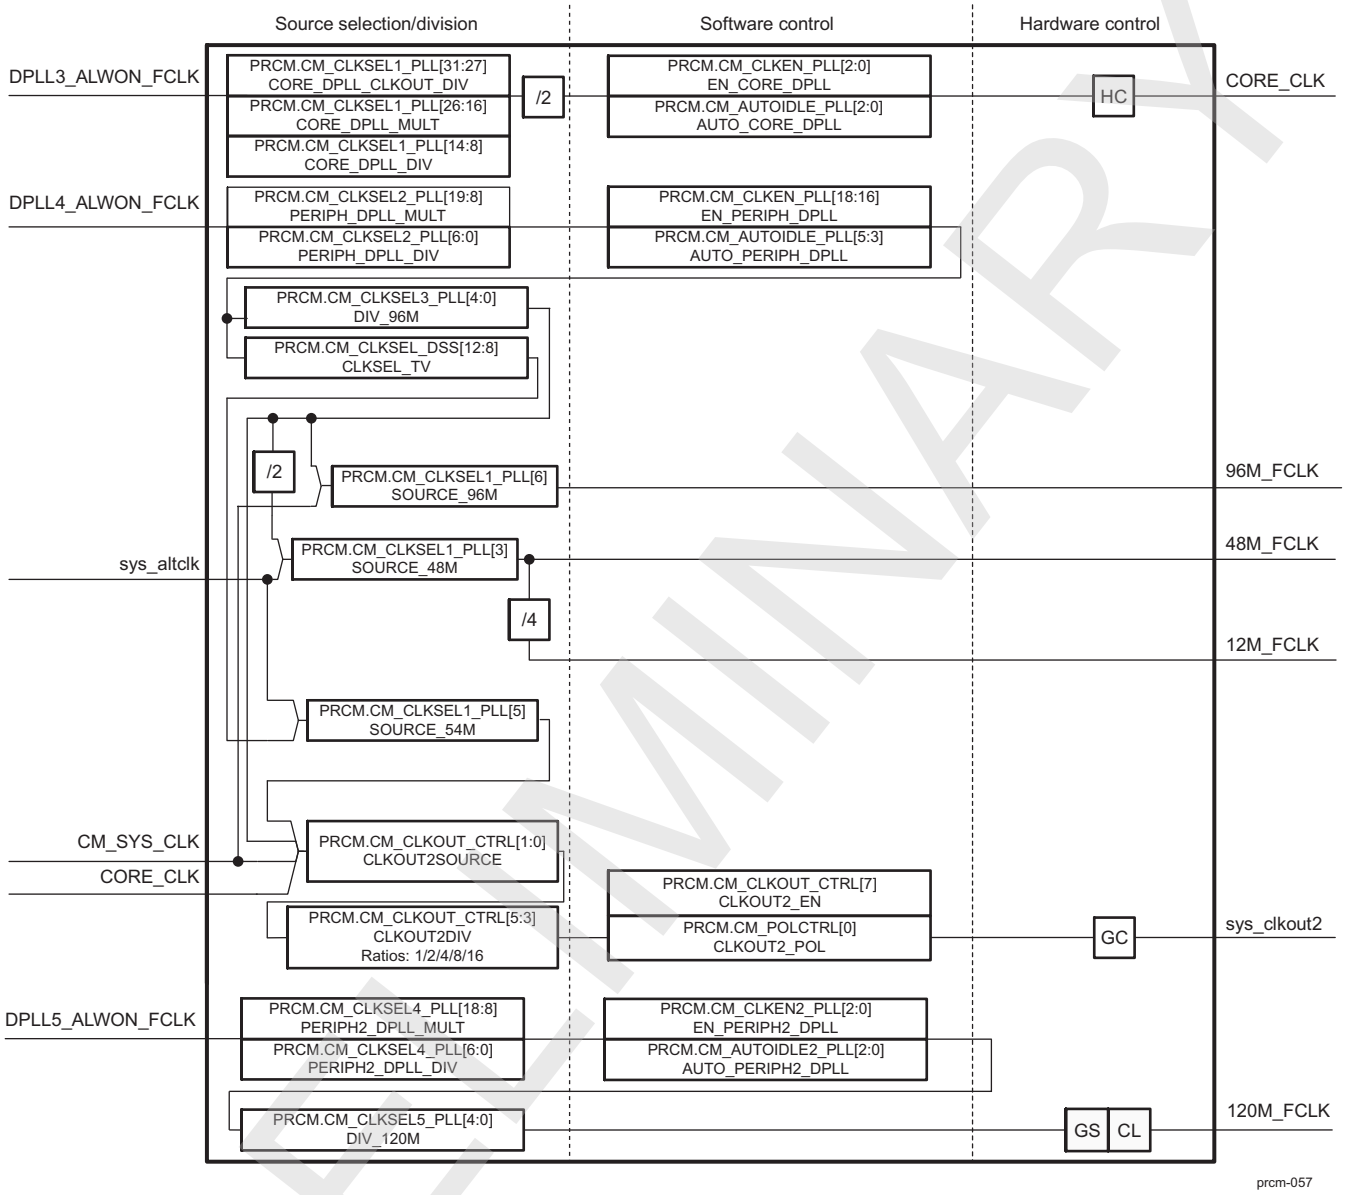

Table 3-46 shows the common source-clock gating controls for the CM.

Table 3-46. Common CM Source-Clock Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
CORE_CLK	Running	Depends on the clock-gating conditions of L3_ICLK and L4_ICLK	Gated when all interface clocks of the different modules of the device are gated
96M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_96M_FCLK	If the dependent clocks are active, the clock is active.
48M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK, PER_48M_FCLK and USBHOST_48M_FCLK	If the dependent clocks are active, the clock is active.
12M_FCLK	Stopped	Depends on the clock-gating conditions of CORE_12M_FCLK	If the dependent clock is active, the clock is active.
sys_clkout2	Stopped	PRCM.CM_CLKOUT_CTRL[7] CLKOUT2_EN	Active if enabled
DPLL4_M2_CLK	Stopped	Depends on the clock-gating conditions of: 96M_FCLK	If the dependent clocks are active, the clock is active.
DPLL4_M3_CLK	Stopped	CM_CLKSEL1_PLL.SOURCE_54M and depends on the clock-gating conditions of: DPLL4_M2_CLK and DSS_TV_CLK	If the dependent clocks are active, the clock is active. DSS_TV_CLK is a dependent clock if set by the register configuration.
120M_FCLK	Stopped	CM_FCLKEN_USBHOST[1] EN_USBHOST2, CM_FCLKEN3_CORE[2] EN_USBTLL	If any of the dependent clocks (CORE_120M_FCLK or USBHOST_12M_FCLK) is active, the clock is active.

3.5.3.7.3 Common Interface Clock Controls

Figure 3-62 shows the clock controls for the common interface.

Figure 3-62. Common Interface Clock Controls

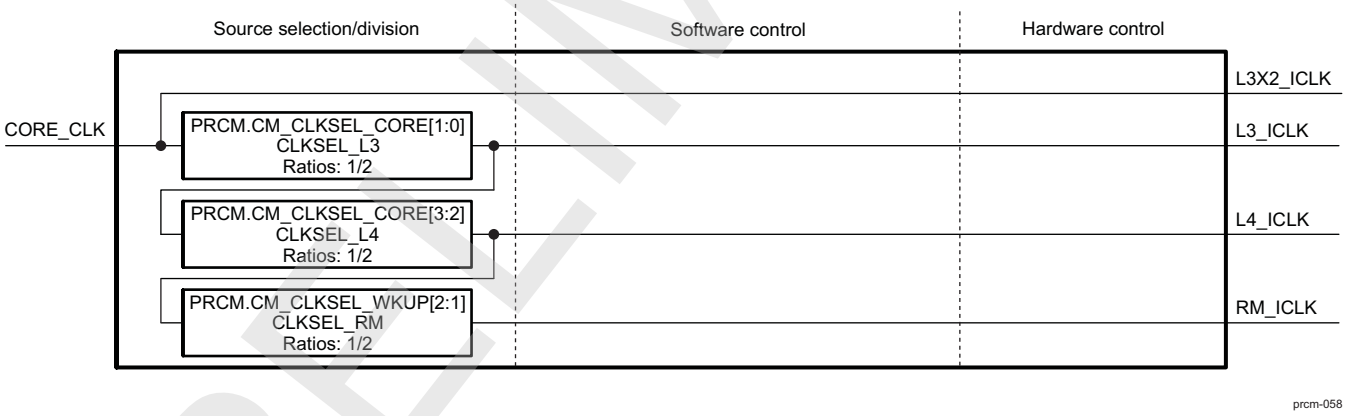

Table 3-47 shows the clock-gating controls for the common interface.

Table 3-47. Common Interface Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
L3X2_ICLK	Running	CORE_CLK gating conditions	Depends on the gating conditions of the CORE_CLK
L3_ICLK	Running	Depends on the clock-gating conditions of GFX_L3_ICLK, CORE_L3_ICLK, and CAM_L3_ICLK	Gated when all L3 interface clocks of the different modules of the device are gated
L4_ICLK	Running	Depends on the clock-gating conditions of CORE_L4_ICLK, CAM_L4_ICLK, DSS_L4_ICLK, PER_L4_ICLK, SR_L4_ICLK, and WKUP_L4_ICLK	Gated when all L4 interface clocks of the different modules of the device are gated
RM_ICLK	Running	None	Gated with source clock (CORE_CLK)

3.5.3.7.4 DPLL Source-Clock Controls

Figure 3-63 shows the clock controls for the DPLL power domain.

Figure 3-63. DPLL Power Domain Clock Controls

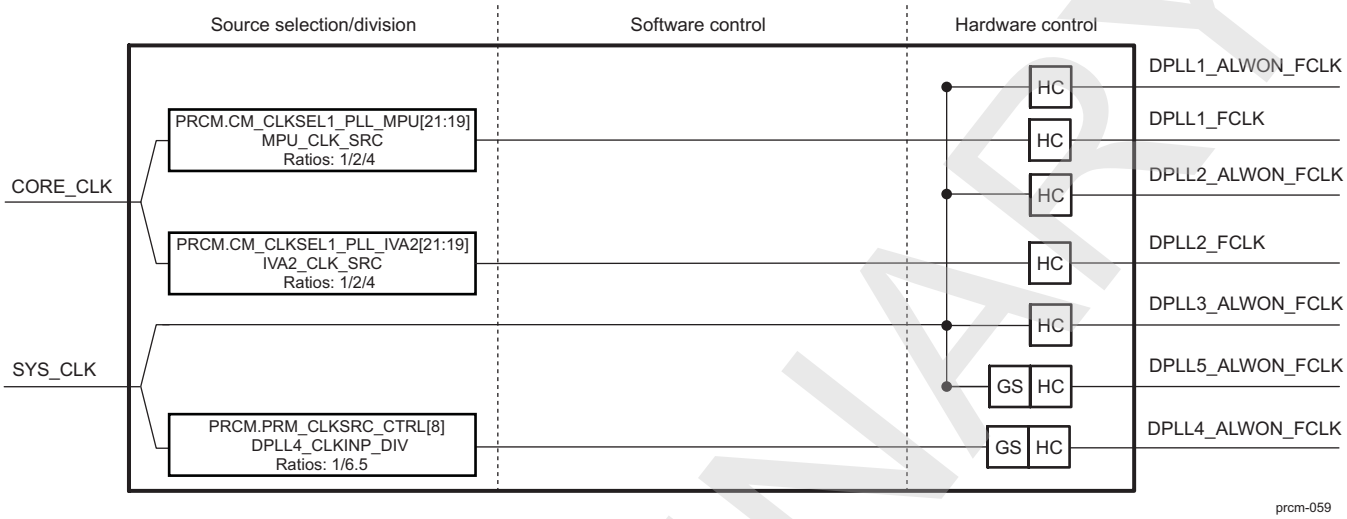

Table 3-48 shows the clock-gating controls for the DPLL power domain.

Table 3-48. DPLL Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DPLL1_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL, PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL, and MPU domain power state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the MPU power domain goes into retention or off mode. Also gated if DPLL is set to low-power bypass mode.
DPLL1_FCLK	Stopped		
DPLL2_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL, PRCM.CM_CLKEN_PLL_IVA2[2 :0] EN_IVA2_DPLL, and IVA2 power domain power state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the IVA2 power domain goes into retention or off mode. Also gated if DPLL is set to low-power stop or bypass mode.
DPLL2_FCLK	Stopped		
DPLL3_ALWON_FCLK	Running	PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL, PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL, and CORE domain power clocks state	Gated if the DPLL is set to automatic active control and enabled in lock mode while the CORE power domain is idle. Also gated if DPLL is set to low-power or fast-relock bypass mode.
DPLL4_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL, PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL, and depends on the clock-gating conditions of DPLL4_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. Also gated if DPLL is set to low-power stop mode.
DPLL5_ALWON_FCLK	Stopped	PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL, PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL, and depends on the clock-gating conditions of DPLL5_M2_CLK	Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. Also gated if DPLL is set to low-power stop mode.

3.5.3.7.5 SGX Power Domain Clock Controls

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 3-64 shows the clock controls for the SGX power domain.

Figure 3-64. SGX Power Domain Clock Controls

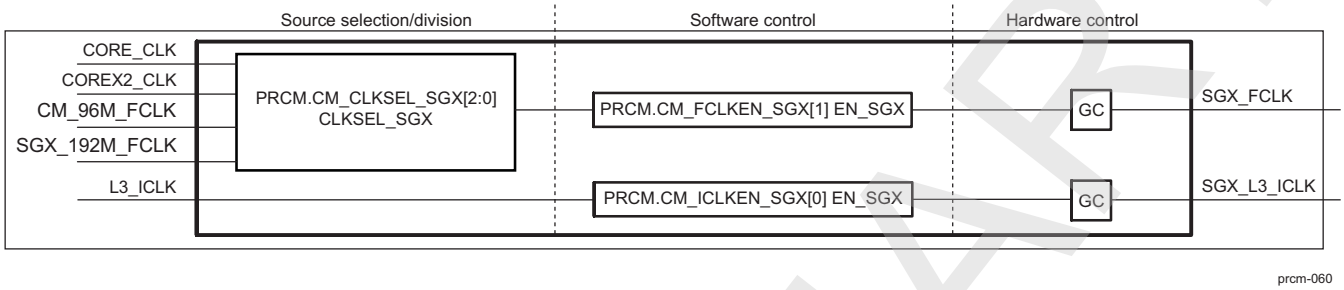

Table 3-49 lists the clock-gating controls for the SGX power domain.

Table 3-49. SGX Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
SGX_FCLK	Stopped	PRCM.CM_FCLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0
SGX_L3_ICLK	Stopped	PRCM.CM_ICLKEN_SGX[1] EN_SGX	Gated when the enable bit is set to 0

3.5.3.7.6 CORE Power Domain Clock Controls

Figure 3-65 through Figure 3-66 show the clock controls for the CORE power domain.

Figure 3-65. CORE Power Domain Clock Controls: Part 1

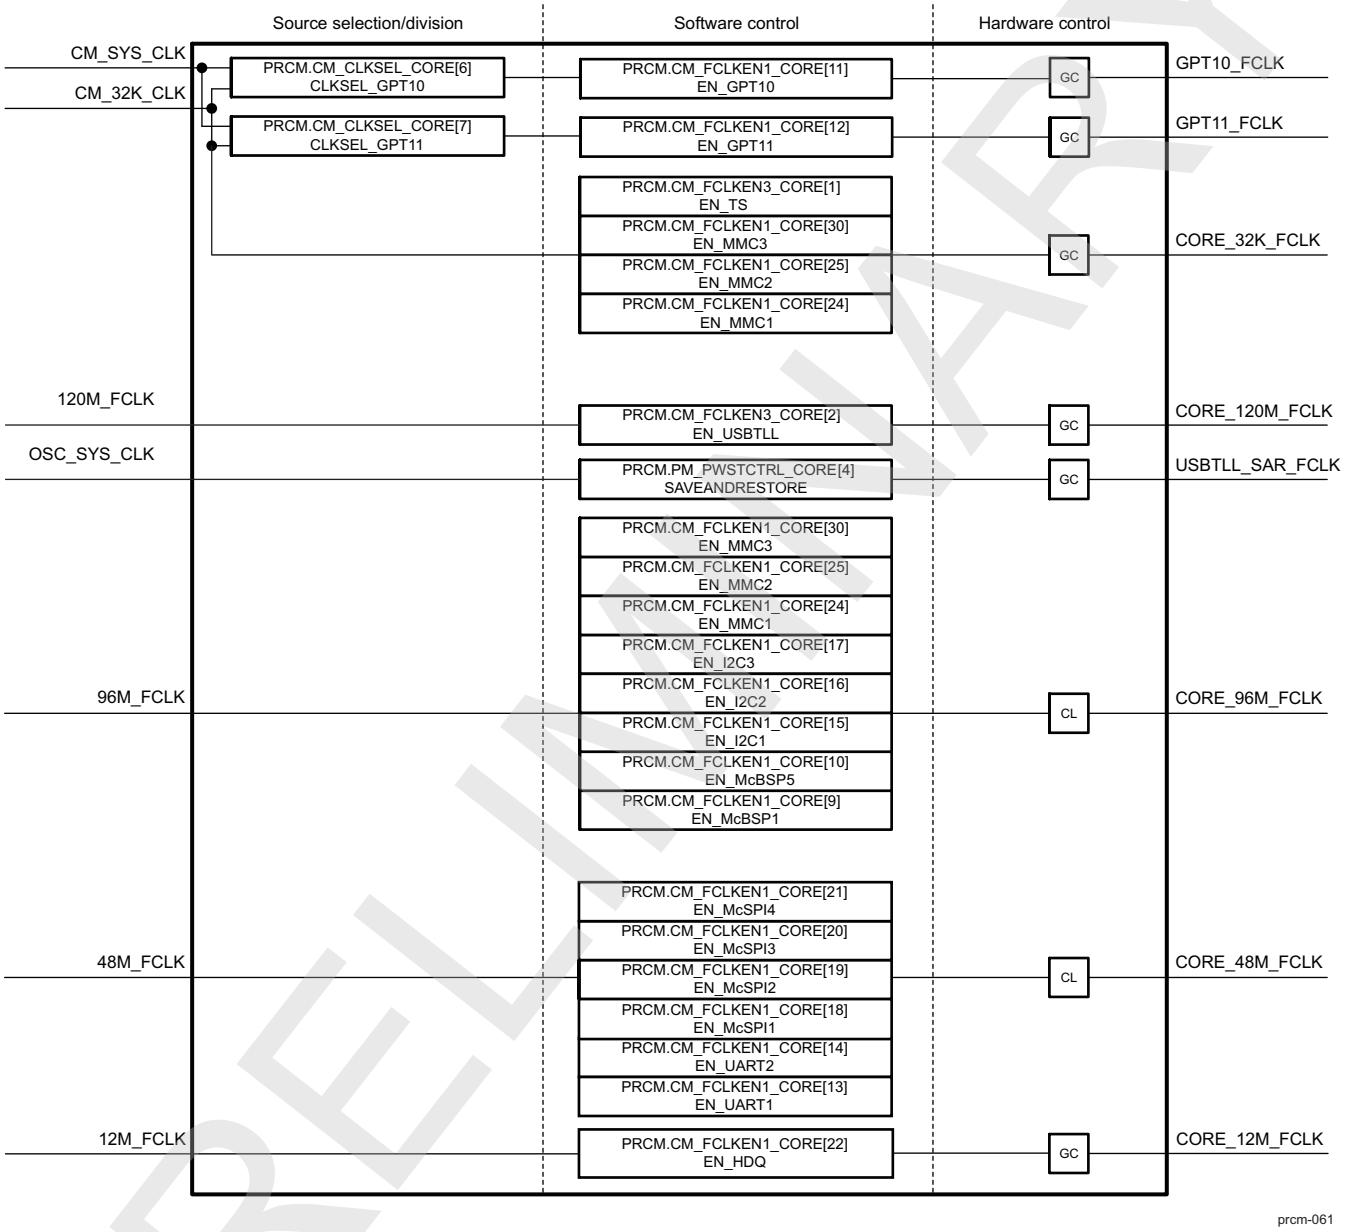

Figure 3-66. CORE Power Domain Clock Controls: Part 2

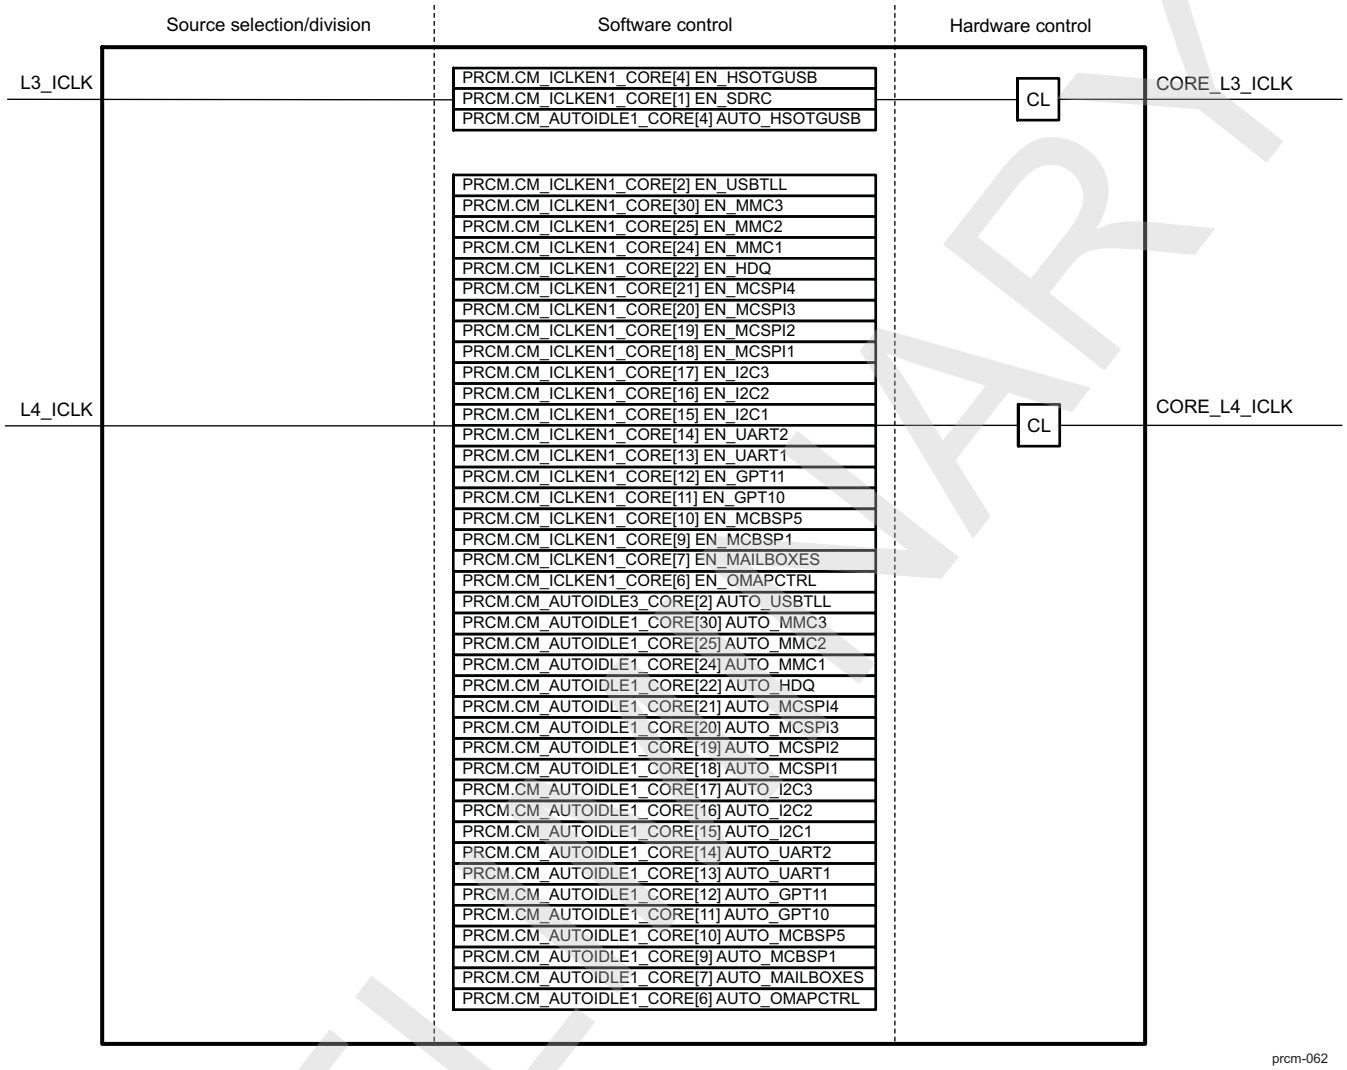

Table 3-50 lists the clock-gating controls for the CORE power domain.

Table 3-50. CORE Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
GPT10_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[11] EN_GPT10	Gated when the enable bit is set to 0
GPT11_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[12] EN_GPT11	Gated when the enable bit is set to 0
CORE_96M_FCLK	Stopped	McBSP[1..5] input clock source select (in SCM) and PRCM.CM_FCLKEN1_CORE (MMC[1-2], McBSP[1, 5], I2C[1-3])	Gated when the enable bits of the module functional clock are set to 0. (The McBSPs can have MCBSP_CLKS as an alternate functional clock.)
CORE_48M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE (UART[1-2], McSPI[1-4])	Gated when the functional clock enable bits of the module are set to 0
CORE_12M_FCLK	Stopped	PRCM.CM_FCLKEN1_CORE[22] EN_HDQ	Gated when the enable bit is set to 0

Table 3-50. CORE Power Domain Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
CORE_L3_ICLK	Running	PRCM.CM_ICLKEN1_CORE EN_(SDRC, HSOTGUSB), PRCM.CM_AUTOIDLE1_CORE4] AUTO_HSOTGUSB	Gated when: • All enable bits are set to 0. • The enable-autoidle bit pair is set to 1, the remaining enable bits are set to 0, and the clock is not requested by any module.
CORE_L4_ICLK	Running	PRCM.CM_ICLKEN1_CORE (MMC[1..2], HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], MAILBOXES, OMAPCTRL) and PRCM.CM_AUTOIDLE1_CORE (MMC[1..2], HDQ, MCSPI[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], MAILBOXES, OMAPCTRL)	Gated when: • All enable bits are set to 0. • All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
CORE_32K_FCLK	Stopped	CM_FCLKEN1_CORE[24] EN_MMC1, CM_FCLKEN1_CORE[25] EN_MMC2, CM_FCLKEN1_CORE[30] EN_MMC3, CM_FCLKEN3_CORE[1] EN_TS	Gated when all enable bits are set to 0
USBTLL_SAR_FCLK	Stopped	CORE power domain power state and PM_PWSTCTRL_CORE[4] SAVEANDRESTORE	Gated when the save-restore bit is set to 0, or when the CORE power domain is in off state after the save operation completes or in on state after the restore operation completes
CORE_120M_FCLK	Stopped	CM_FCLKEN3_CORE[0] EN_USBTLL and DPLL5 operating mode	Gated when the enable bit is set to 0, or the DPLL5 is in stop or bypass mode

3.5.3.7.7 EFUSE Power Domain Clock Controls

Figure 3-67 shows the clock controls for the EFUSE power domain. Table 3-51 lists the clock-gating control for the EFUSE power domain.

Figure 3-67. EFUSE Power Domain Clock Controls

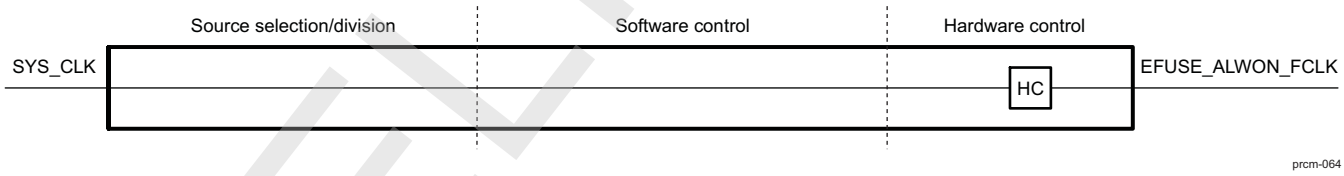

Table 3-51. EFUSE Power Domain Clock-Gating Control

Clock Name	Reset	Clock-Gating Control	Gating Description
EFUSE_ALWON_FCLK	Running	None	Active when VDD1 and VDD2 are switched on and eFuse-ready hardware signal is released

3.5.3.7.8 DSS Power Domain Clock Controls

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 3-68 shows the clock controls for the DSS power domain. Table 3-52 lists the clock-gating controls for the DSS power domain.

Figure 3-68. DSS Power Domain Clock Controls

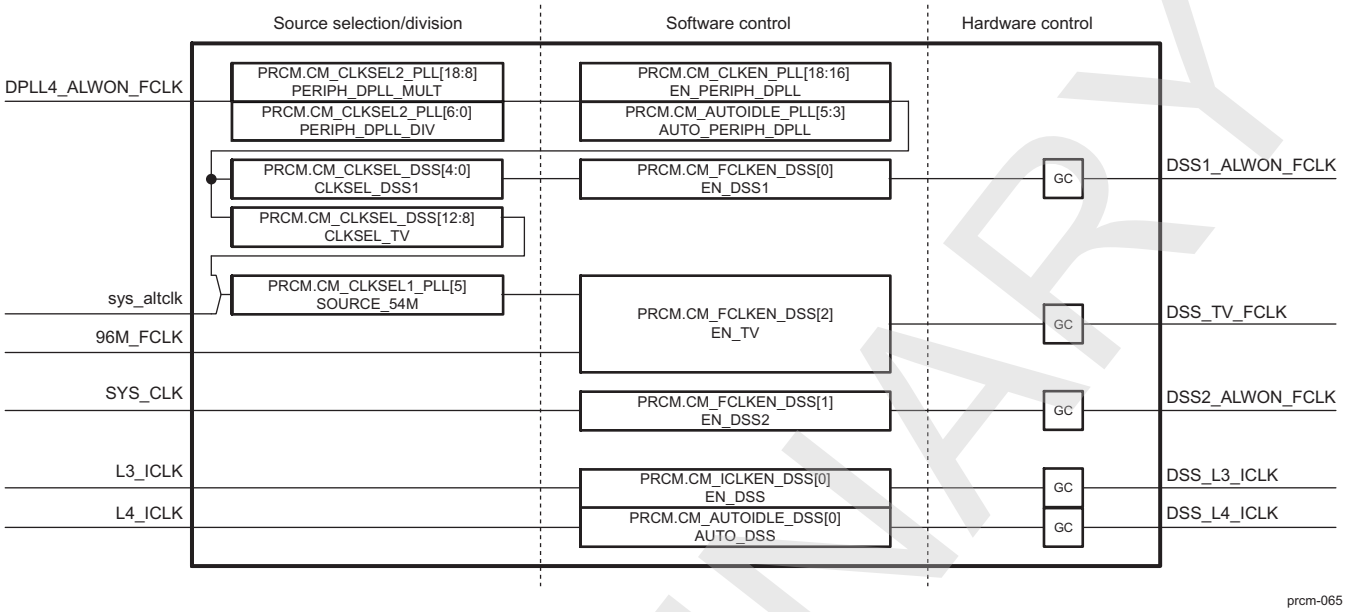

Table 3-52. DSS Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
DSS1_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[0] EN_DSS1	Gated when the enable bit is set to 0
DSS2_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[1] EN_DSS2	Gated when the enable bit is set to 0
DSS_TV_FCLK	Stopped	PRCM.CM_FCLKEN_DSS[2] EN_TV	Gated when the enable bit is set to 0
DSS_L3_ICLK	Stopped	PRCM. CM_ICLKEN_DSS[0] EN_DSS, PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS	Gated when: • Enable bit is set to 0. • Enable-autoidle bit pair is set to 1, and the clock is not requested by any module.
DSS_L4_ICLK	Stopped		

3.5.3.7.9 CAM Power Domain Clock Controls

This section describes all modules and features in the high-tier device. To save power, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Figure 3-69 shows the clock controls for the CAM power domain. Table 3-53 lists the clock-gating controls for the CAM power domain.

Figure 3-69. CAM Power Domain Clock Controls

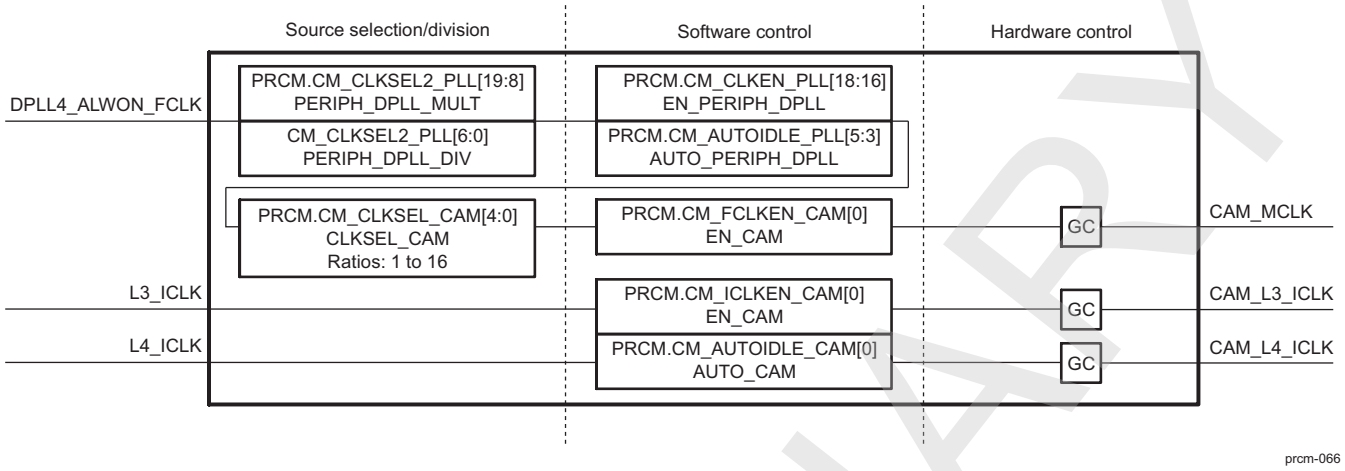

Table 3-53. CAM Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
CAM_MCLK	Stopped	PRCM.CM_FCLKEN_CAM[0] EN_CAM	Gated when the enable bit is set to 0
CAM_L3_ICLK	Stopped	PRCM.CM_ICLKEN_CAM[0] EN_CAM, PRCM.CM_AUTOIDLE_CAM[0] AUTO_CAM	Gated when: • Enable bit is set to 0. • Enable-autoidle bit pair is set to 1, and the clock is not requested by subsystem.
CAM_L4_ICLK	Stopped		

3.5.3.7.10 USBHOST Power Domain Clock Controls

Figure 3-70 shows the clock controls for the USBHOST power domain. Table 3-54 lists the clock-gating controls for the USBHOST power domain.

Figure 3-70. USBHOST Power Domain Clock Controls

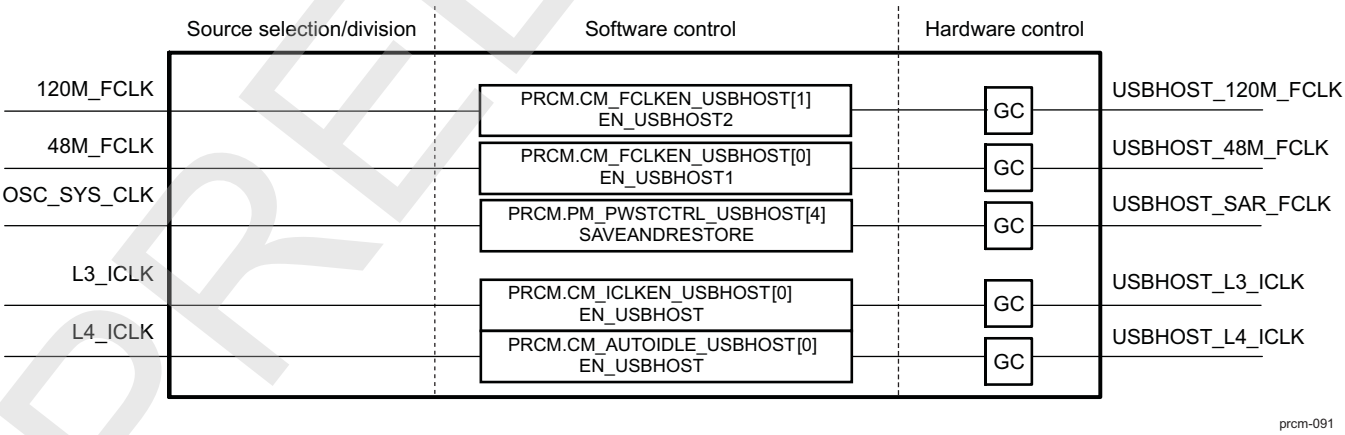

Table 3-54. USBHOST Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
USBHOST_48M_FCLK	Stopped	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1	Gated when the enable bit is set to 0

Table 3-54. USBHOST Power Domain Clock-Gating Controls (continued)

Clock Name	Reset	Clock-Gating Control	Gating Description
USBHOST_120M_FCLK	Stopped	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2	Gated when the enable bit is set to 0
USBHOST_L3_ICLK	Stopped	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST, PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST	Gated when: • Enable bit is set to 0. • Enable-autoidle bit pair is set to 1, and the clock is not requested by subsystem.
USBHOST_L4_ICLK	Stopped		
USBHOST_SAR_FCLK	Stopped	PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE	Gated when the save-restore bit is set to 0, or when the power domain is in off state after the save operation completes or in on state after the restore operation completes.

3.5.3.7.11 WKUP Power Domain Clock Controls

Figure 3-71 shows the clock controls for the WKUP power domain. Table 3-55 lists the clock-gating controls for the WKUP power domain.

Figure 3-71. WKUP Power Domain Clock Controls

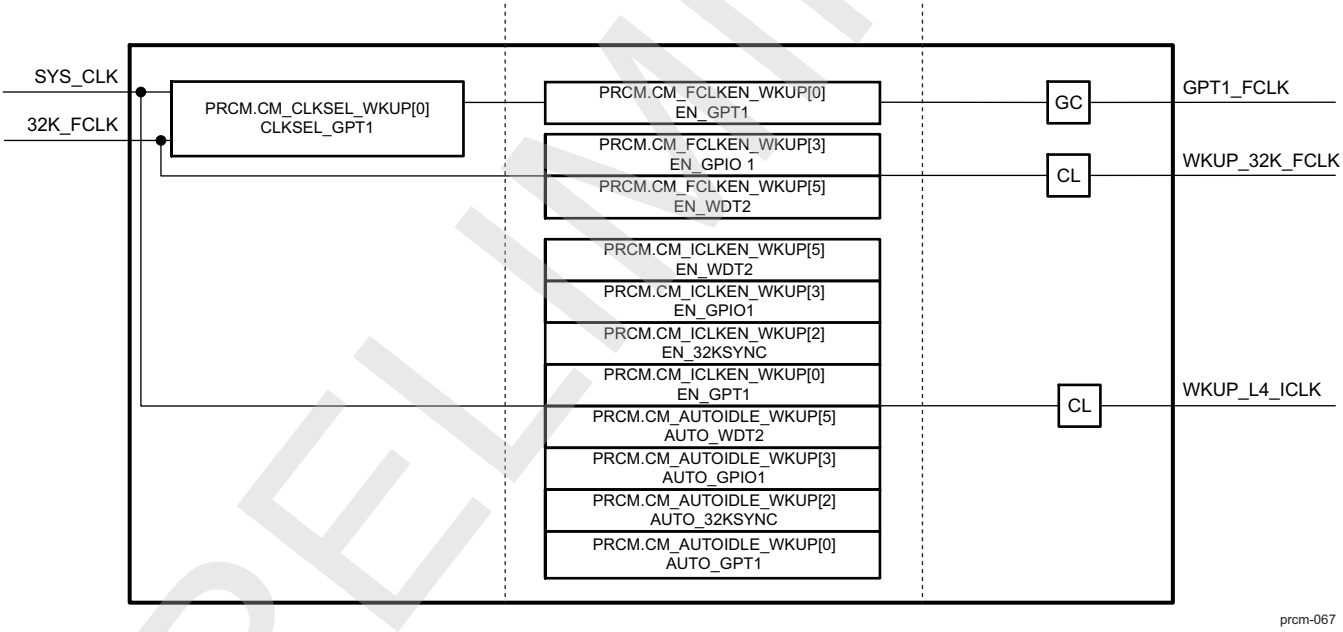

Table 3-55. WKUP Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
GPT1_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[0] EN_GPT1	Gated when the enable bit is set to 0
WKUP_32K_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[3] GPIO1 and PRCM.CM_FCLKEN_WKUP[5] WDT2	Gated when the enable bits are set to 0
WKUP_L4_ICLK	Running	PRCM.CM_ICLKEN_WKUP EN_(WDT2, GPIO1, 32KSYNC, GPTIMER1), PRCM.CM_AUTOIDLE_WKUP AUTO_(WDT2, GPIO1, 32KSYNC, and GPTIMER1)	Gated when: • All enable bits are set to 0. • All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.

3.5.3.7.12 PER Power Domain Clock Controls

Figure 3-72 and Figure 3-73 show the clock controls for the PER power domain.

Figure 3-72. PER Power Domain Clock Controls: Part 1

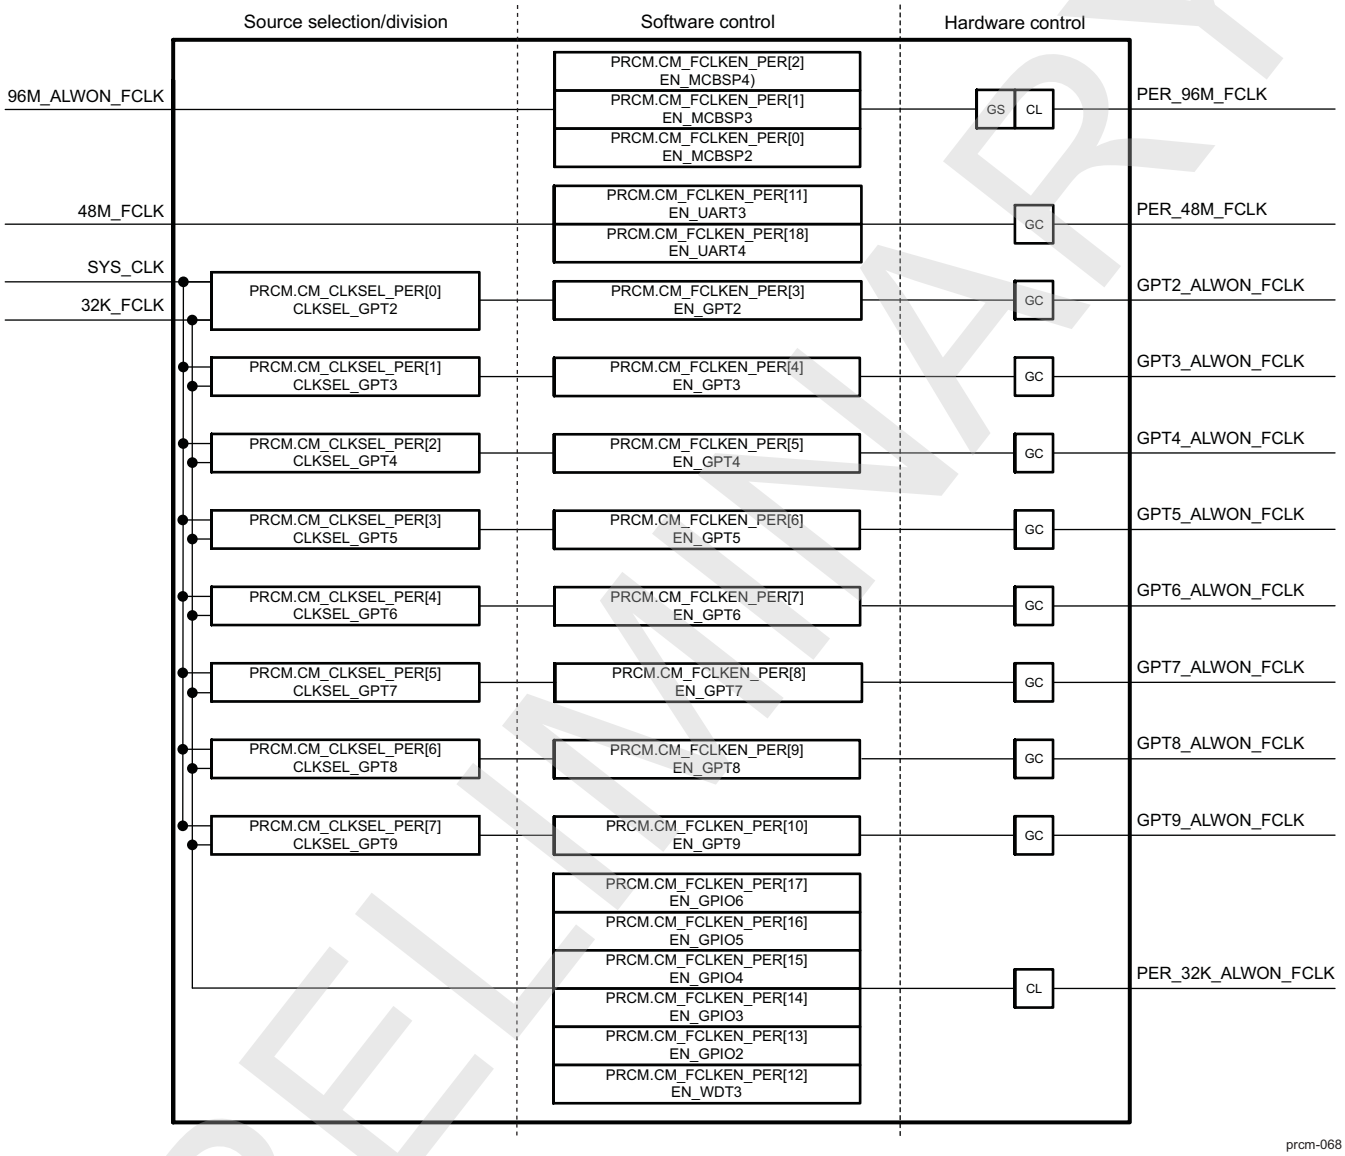

Figure 3-73. PER Power Domain Clock Controls: Part 2

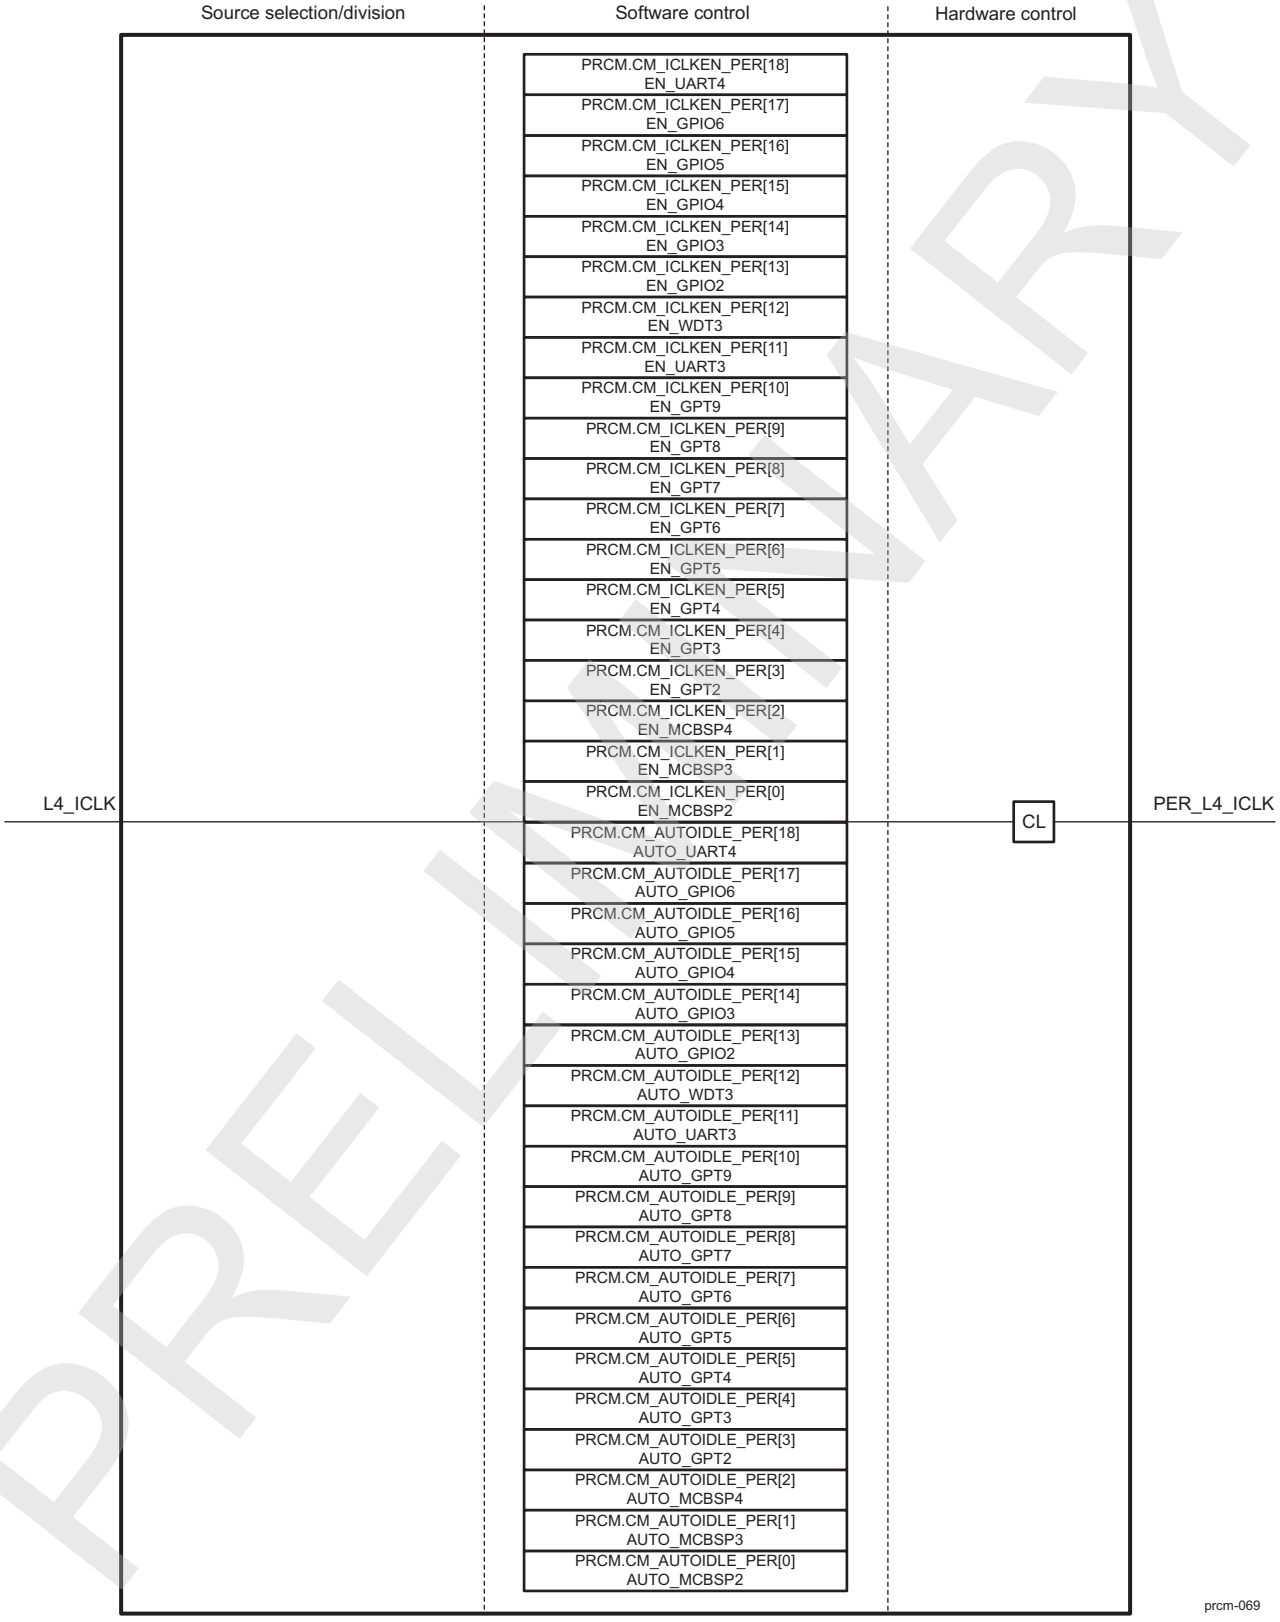

Table 3-56 lists the clock-gating controls for the PER power domain.

Table 3-56. PER Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
PER_48M_FCLK	Stopped	PRCM.CM_FCLKEN_PER EN_UART[3-4]	Gated when the enable bit is set to 0
PER_96M_FCLK	Stopped	McBSP[2..4] input clock source select (in SCM) and PRCM.CM_FCLKEN_PER EN_MCBSP[2-4] and the DPLL4 operating mode	Gated when the enable bits of the module functional clock are set to 0 (the McBSPs can have MCBSP_CLKS as an alternate functional clock) or DPLL4 is in stop or bypass mode
MCBSP_CLKS	Stopped	See Chapter 13, *System Control Module*.	
PER_32K_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER EN_GPIO[2-6] and PRCM.CM_FCLKEN_PER[12] EN_WDT3	Gated when all the enable bits are set to 0
GPT2_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[3] EN_GPT2	Gated when the enable bit is set to 0
GPT3_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[4] EN_GPT3	Gated when the enable bit is set to 0
GPT4_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[5] EN_GPT4	Gated when the enable bit is set to 0
GPT5_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[6] EN_GPT5	Gated when the enable bit is set to 0
GPT6_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[7] EN_GPT6	Gated when the enable bit is set to 0
GPT7_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[8] EN_GPT7	Gated when the enable bit is set to 0
GPT8_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[9] EN_GPT8	Gated when the enable bit is set to 0
GPT9_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_PER[10] EN_GPT9	Gated when the enable bit is set to 0
PER_L4_ICLK	Stopped	PRCM.CM_ICLKEN_PER EN_(GPIO[2..6], WDT3, UART[3, 4], GPT[2..9], MCBSP[2..4]) and PRCM.CM_AUTOIDLE_PER AUTO_(GPIO[2..6], WDT3, UART[3, 4], GPT[2..9], and MCBSP[2..4])	Gated when: • All enable bits are set to 0. • All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module.
96M_ALWON_FCLK	Stopped	None	Always-on clock

For audio applications, the McBSP functional clocks are provided externally by the MCBSP_CLKS pin. This clock must be permanently supplied, to let McBSPs function when the CORE power domain is in the off power state. If the external clock input is selected as the functional clock, the PER power domain sleep transition is prevented.

3.5.3.7.13 SMARTREFLEX Power Domain Clock Controls

Figure 3-74 shows the clock controls for the SMARTREFLEX power domain. Table 3-57 lists the clock-gating controls for the SMARTREFLEX power domain.

Figure 3-74. SMARTREFLEX Power Domain Clock Controls

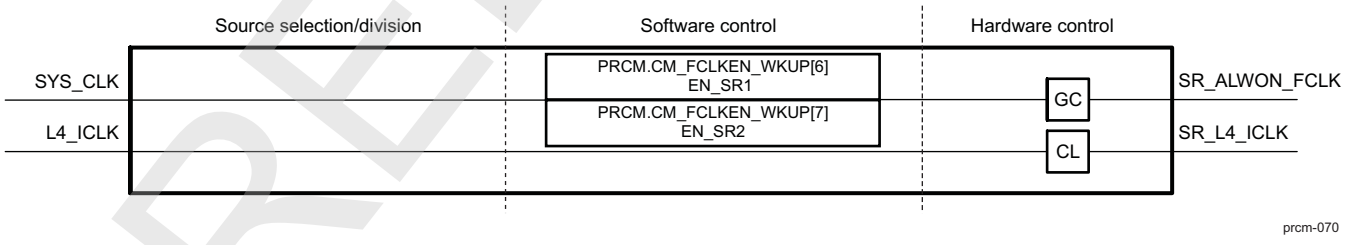

Table 3-57. SMARTREFLEX Power Domain Clock-Gating Controls

Clock Name	Reset	Clock-Gating Control	Gating Description
SR_ALWON_FCLK	Stopped	PRCM.CM_FCLKEN_WKUP[6] EN_SR1 and PRCM.CM_FCLKEN_WKUP[7] EN_SR2	Gated when both enable bits are set to 0
SR_L4_ICLK	Running	Depends on L4_ICLK activity (hardware control)	

3.5.3.8 Clock Configurations

The device supports several clock configurations. A clock configuration is a consistent set of divider ratios programmed into the PRCM module to obtain a certain combination of clock speed to match the performance requirement.

In the device, the MPU and IVA2.2 processors are connected to the interconnects through asynchronous bridges. The functional frequency of these processors can be configured independently of their interface clock frequency.

Therefore, the clock configurations of the device are split into two sections: one for device processor clocks and one for device interface clocks.

An OPP of the device can be defined as a pair of device operating voltage and corresponding frequency. The device processors are in the VDD1 voltage domain and the interface clocks are generated by the CM clock generator in the VDD2 voltage domain. Hence, the OPPs of the processor clocks are identified for the VDD1 voltage levels, independent of the interface clocks, which are associated with the VDD2 voltage levels.

CAUTION

Clock configuration frequencies depend on the device operating voltage values.

3.5.3.8.1 Processor Clock Configurations

The processor OPPs are identified as the pair of VDD1 operating voltage level and processor clock frequency.

Four generic processor OPPs can be defined as:

1. OPP1G (VDD1 = v3, (MPU_CLK = $f_{mpu}3$, IVA2_CLK = $f_{iva}3$))
2. OPP130 (VDD1 = v2, (MPU_CLK = $f_{mpu}2$, IVA2_CLK = $f_{iva}2$))
3. OPP100 (VDD1 = v1 , (MPU_CLK = $f_{mpu}1$, IVA2_CLK = $f_{iva}1$))
4. OPP50 (VDD1 = v0 , (MPU_CLK = $f_{mpu}0$, IVA2_CLK = $f_{iva}0$))

where v3 > v2 > v1 > v0,

$f_{mpu}3 > f_{mpu}2 > f_{mpu}1 > f_{mpu}0$,

$f_{iva}3 > f_{iva}2 > f_{iva}1 > f_{iva}0$ and

f_{mpu} may not be equal to f_{iva}

The clock configuration for the MPU and the IVA applies to the following clocks of the device:

- DPLL1 (MPU DPLL) synthesized clock frequency (CLKOUT) configured by setting the M and N parameters of the DPLL
- DPLL1 (MPU DPLL) output clock frequency (MPU_CLK) configured by setting the M2 parameter of the DPLL

NOTE: The MPU_CLK is used to generate the ARM_FCLK. ARM_FCLK is equal to MPU_CLK (For information about ARM_FCLK, see Chapter 4, *MPU Subsystem*.)

- DPLL2 (IVA2 DPLL) synthesized clock frequency (CLKOUT) configured by setting the M and N parameters of the DPLL
- DPLL2 (IVA2 DPLL) output clock frequency (IVA2_CLK) configured by setting the M2 parameter of the DPLL

The frequency of the processor clocks (MPU_CLK and IVA2_FCLK) must be configured according to the selected OPP (the clock frequency associated with the operating voltage VDD1). Table 3-58 identifies the clocks of the processors, their source clocks, and the configuration register bit fields.

Table 3-58. Processor Clock Configuration Controls

Module	Clocks	Reference Clock	Multiplier (Factors)	Divider (Factors)	Configuration Bits
DPLL1	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT
				N (0 ... 127)	PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV
	MPU_CLK (1)	CLKOUTX2		M2	PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV
DPLL2	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL_IVA2[18:8] IVA2_DPLL_MULT
				N (0 ... 127)	PRCM.CM_CLKSEL1_PLL_IVA2[6:0] IVA2_DPLL_DIV
	IVA2_CLK	CLKOUT		M2 (1 ... 16)	PRCM.CM_CLKSEL2_PLL_IVA2[4:0] IVA2_DPLL_CLKOUT_DIV

(1) The MPU_CLK is generating the ARM_FCLK. ARM_FCLK is equal to the MPU_CLK. For information about ARM_FCLK, see Chapter 4, *MPU Subsystem*.

Table 3-59. Processor Clock Configurations

DPLL State	BYPASS	LOCKED
MPU_CLK	DPLL1_FCLK (bypass clock from DPLL3)	(SYS_CLK * M * 2)/([N+1] * M2)
ARM_FCLK	MPU_CLK	MPU_CLK
MPU subsystem internal module clocks	ARM_FCLK/2	ARM_FCLK/2

3.5.3.8.2 Interface and Peripheral Functional Clock Configurations

The interface clock OPPs are identified as the pair of VDD2 operating voltage level and the device interface clocks frequencies.

The DPLL3 (CORE DPLL) generates the CORE_CLK, which serves as the source clock for the L3_ICLK and L4_ICLK interface clocks of the device. The CORE_CLOCK is also used by the DPLL1 and DPLL2 as the bypass clock. The L3_ICLK is supplied to the SGX module as SGX_L3_ICLK and is used as its interface clock. The L4_ICLK is used by RM_L4_CLK as its source clock.

The interface and peripheral functional clock frequencies can be configured according to the device performance requirements for the OPP.

DPLL3 synthesized clock frequencies are configured as:

- $f_{CLKOUT} = (f_{SYS\_CLK} \times M)/(N+1)$
- $f_{CLKOUTX2} = f_{CLKOUT} \times 2$

DPLL3 output clock frequencies are configured as:

- $f_{CORE\_CLK} = f_{CLKOUT}/M2$
- $f_{COREX2\_CLK} = f_{CLKOUTX2}/M2$

L3_ICLK, L4_ICLK and RM_L4_ICLK frequencies are configured as:

- $f_{L3\_ICLK} = f_{CORE\_CLK}/DIV\_L3$
- $f_{L4\_ICLK} = f_{L3\_ICLK}/DIV\_L4$
- $f_{RM\_L4\_ICLK} = f_{L4\_ICLK}/DIV\_RM$

Table 3-60 identifies the interface clocks, their reference clocks, and the control bits for configuration of the interface clock frequencies.

Table 3-60. Interface Clock Configuration Controls

Module	Clock	Reference Clock	Multiplier (Factor)	Divider (Factor)	Configuration Bits
DPLL3	CLKOUT	SYS_CLK	M (0 ... 2047)		PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT
	CLKOUTX2			N (0 ... 127)	PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_ DIV
CORE_CLK	CORE_CLK	CLKOUT		M2 (1 ... 31)	PRCM. CM_CLKSEL1_PLL[31 :27] CORE_DPLL_CLKOUT_DIV
	COREX2_CLK	CLKOUTX2			
L3 interconnect	L3_ICLK	CORE_CLK		DIV_L3 (1 ... 2)	PRCM. CM_CLKSEL_CORE[1:0] CLKSEL_L3
L4 interconnect	L4_ICLK	L3_ICLK		DIV_L4 (1 ... 2)	PRCM.CM_CLKSEL_CORE[3:2] CLKSEL_L4
RM clock	RM_L4_ICLK	L4_ICLK		DIV_RM (1 ... 2)	PRCM.CM_CLKSEL_WKUP[2:1] CLKSEL_RM

SGX_FCLK frequencies are configured depending on the source clock as:

- $f_{SGX\_FCLK} = f_{CORE\_CLK}/DIV\_SGX$
- $f_{SGX\_FCLK} = f_{COREX2\_CLK}/DIV2\_SGX$
- $f_{SGX\_FCLK} = f_{SGX\_192M\_FCLK}$
- $f_{SGX\_FCLK} = f_{CM\_96M\_FCLK}$

DPLL1_FCLK (bypass mode) and DPLL2_FCLK (bypass mode) frequencies are configured as:

- $f_{DPLL1\_FCLK} = f_{CORE\_CLK}/DIV\_DPLL1$
- $f_{DPLL2\_FCLK} = f_{CORE\_CLK}/DIV\_DPLL2$

Table 3-61 identifies the functional clocks, their reference clocks, and the control bits for configuration of the functional clock frequencies.

Table 3-61. Functional Clock Configuration Controls

Module	Clock	Reference Clock	Divider (Factor)	Configuration Bits
SGX	SGX_FCLK	CORE_CLK	DIV_SGX (2, 3, 4, 6)	PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
		COREX2_CLK	DIV2_SGX (3, 5)	PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
		SGX_192M_FCLK		PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
		CM_96M_FCLK		PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX
MPU HS bypass	DPLL1_FCLK	CORE_CLK	DIV_DPLL1 (1, 2, 4)	PRCM.CM_CLKSEL1_PLL_MPU[20:19] MPU_CLK_SRC
IVA2 HS bypass	DPLL2_FCLK	CORE_CLK	DIV_DPLL2 (1, 2, 4)	PRCM.CM_CLKSEL1_PLL_IVA2[20:19] IVA2_CLK_SRC

The rest of the functional clocks are issued from DPLL4 and DPLL5 and remain invariable, regardless of the interface clock configuration. In all clock configurations, any divider ratio to generate functional clocks is applicable, provided it complies with the maximum frequency specification.

CAUTION

Before any transition to OPP50, set the DPLL2 bypass clock to CORE_CLK/2 in the CM_CLKSEL1_PLL_IVA2[20:19] IVA2_CLK_SRC bit field. During the relock phase, the DSP clock is 200 MHz. This has no effect on performance because the DPLL2 relock time is only a few µs

Always set the DPLL1 bypass clock to CORE_CLK/1 in the CM_CLKSEL1_PLL_MPU[20:19] MPU_CLK_SRC bit field.

3.5.4 PRCM Idle and Wake-Up Management

3.5.4.1 Overview

When a group of modules belonging to a clock domain in a power domain does not require a clock (interface or functional), the PRCM module can be programmed to automatically cut the clock to these modules, thereby reducing their power consumption. The PRCM module can then switch the power domain to low-power retention or off mode to ensure minimum power consumption. When all clocks in a domain are cut, the domain is idle.

Similarly, when a module belonging to a power domain in low-power idle mode is required to switch to active mode, the PRCM module switches on the power to the entire power domain and activates the necessary clock signals to the module. This is a wake-up transition. Generally, a wake-up event triggers the wake-up transition.

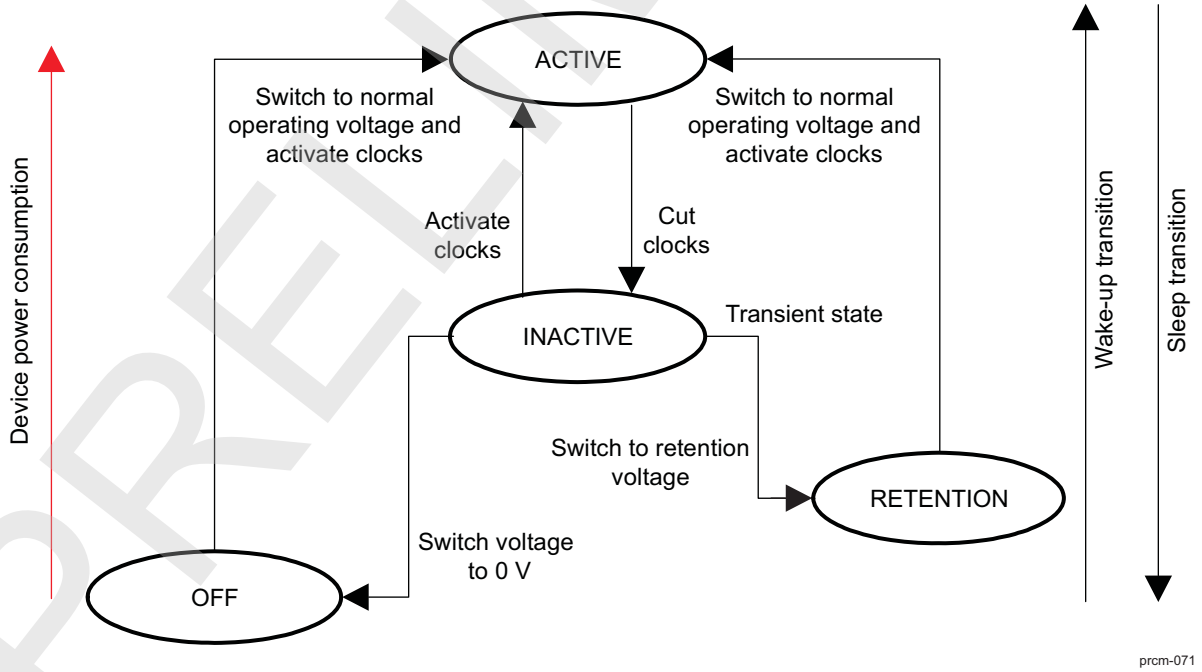
A sleep/wake-up dependency can be defined between power domains. A sleep dependency ensures that a power domain does not make a sleep transition unless all the dependent power domains are in idle mode and do not require the power domain. Similarly, a wake-up dependency ensures that a power domain wakes up when any of its dependent power domains wakes up.

The PRCM module automatically handles the sequence clock-gating conditions and power switching for each power domain, based on the configured dependencies between the domains and the clock-control bits of the modules.

Figure 3-75 shows the sleep/wake-up transition of the power domains. The inactive state is a transient power state of a power domain, while moving from active to retention or off power state. In inactive state, all the domain clocks are gated. A power domain cannot switch from off to retention or retentiON to OFF power state without passing to the active power state.

A low-power state (inactive, retention, or off) means less power consumption. However, wake-up latency increases as the power domain switches to inactive, retention, or off power state.

Figure 3-75. Power Domain Sleep/Wake-Up Transition



Functionally, the PRCM module is composed of a single global control block and a power-control block for each power domain. The domain power-control block handles power switching, wake-up events, and clock-gating control for the domain. The domain power controllers communicate with each other for power sequencing, sleep dependencies, and wake-up dependencies. All these blocks interact with the global control block that handles reset management, clock generation and distribution, and all PRCM registers.

Figure 3-76. Device Power Reset and Clock Controllers

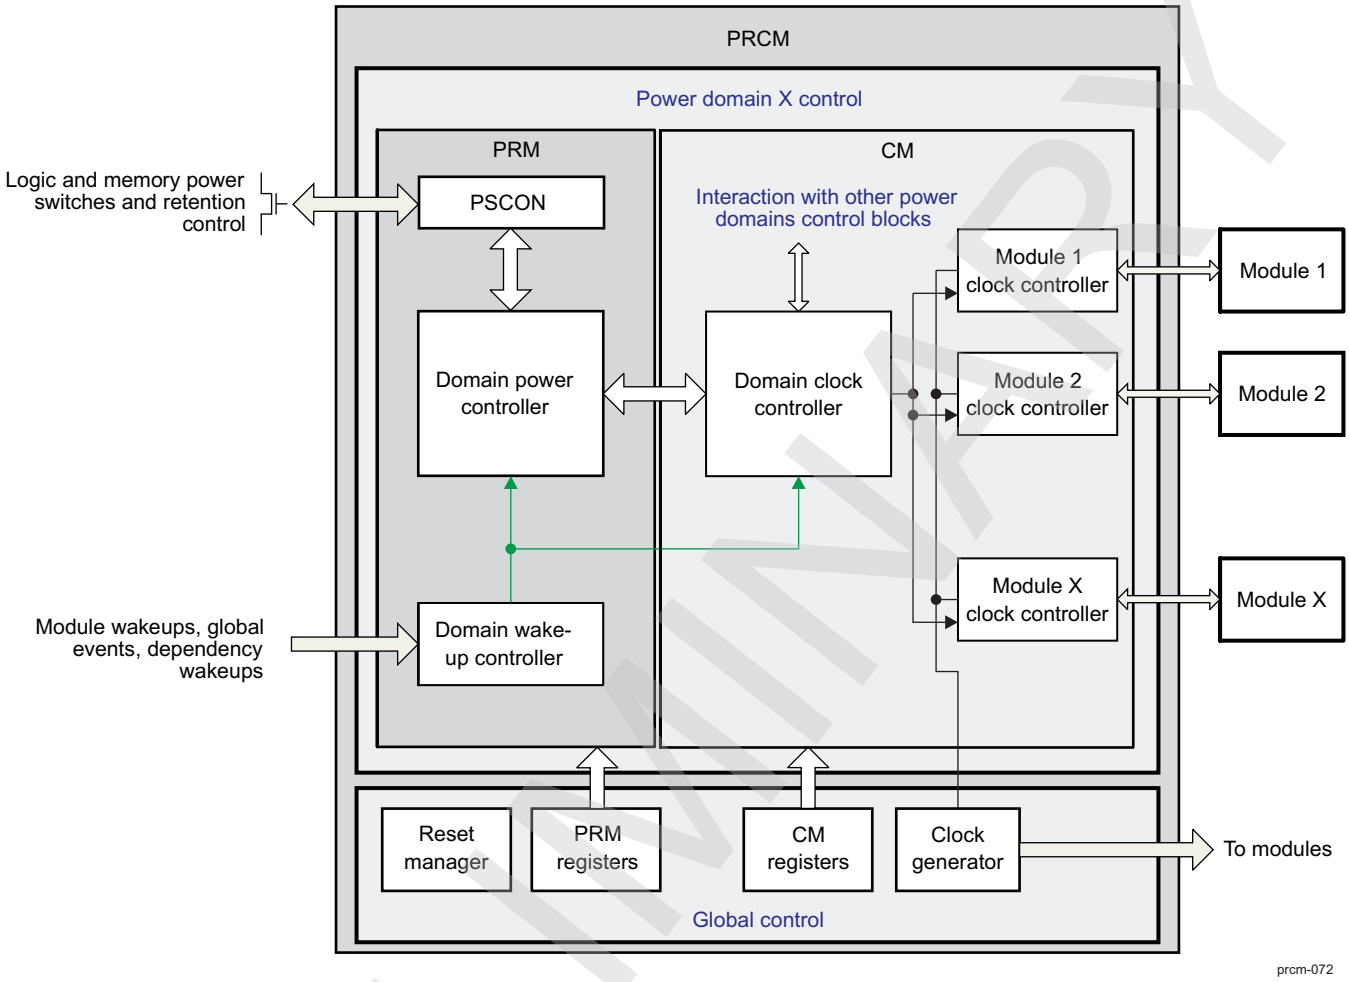


Figure 3-76 shows the functions in one power domain block:

- A module clock controller (for example, module X clock controller) uses a hardware handshake protocol to communicate directly with the module. It controls the idle transition of the target module and responds to the standby requests of the initiator module (for details, see Section 3.1.4.2, *Autoidle Clock Control*). Depending on the mode, the clock controller sends clock commands (enable/disable) to the clock generator. The registers that control the functional and interface clocks in the module are directly mapped to the module clock controller.
- The domain clock controller gathers information from the following:
  - All module clock controllers of the power domain
  - The domain power controller
  - The domain wake-up controller
  - The other power domain control blocks

  The domain clock controller informs the domain power controller when all conditions for the domain power transition are met (domain clocks are idle, no initiator is requesting service, no wake-up event is pending) to allow a domain power transition. On a wake-up event, the domain clock controller starts the module domain clocks, if power is present.
- The domain power controller communicates with the domain clock controller, the domain wake-up controller, and PSCON. Depending on the register settings for clock domain activity (idle or active), it sends requests to the PSCON to power down/up the domain logic and memory, or to enable retention mode.
- The PSCON sequences all sleep and wake-up transitions between on, off, and retention modes for logic and memory. It also ensures that the domain is correctly isolated when it enters off or retention

mode.

- The domain wake-up controller gathers all events that can wake up the power domain. Some events are active only when the domain is on (these switch on the clocks, when required); others also allow domain power up. These events can be internal (coming from the modules in the power domain, such as general-purpose [GP] timer time-out), external (coming from another power domain control block dependency), or global (voltage stabilization).
- The reset manager globally controls all resets in the device. It gathers information from all power domain control blocks to sequence power and clocks, and resets the activation of each domain.
- The clock generator generates and distributes clocks over the device, depending on requests from all module clock controllers and on other global conditions.

3.5.4.2 Sleep Transition

The PRCM module can initiate a domain sleep transition on a power domain only if the domain meets the following conditions:

- All initiator modules are idle (they have completed their activity and idled themselves through software requests).
- All target modules are idle (automatically when all initiators are in standby mode or on software request).
- All sleep dependencies with other domains are met (can be set by software).

When the sleep conditions are met (based on the settings of the PRCM.PRM_PWSTCTRL_<power domain>[1,0] POWERSTATE bit field), the PRCM module performs the actions described in Table 3-62 automatically or when instructed by the software.

Table 3-62. Power-State-Related Sleep Transition Actions

Power Domain State	Action
ON	All functional and interface clocks in the power domain are shut down when the sleep conditions are met. The power domain is idle and is not functional.
Retention	The power domain is idle and part or all of the logic and memory of the domain is switched to retention mode.
Off	The domain is idled and all the logic and memory in the domain are switched off.

The power domain state transition can be set to automatic (hardware controlled) or software-controlled by setting the PRCM. CM_CLKSTCTRL_<power domain> CLKTRCTRL_<power domain> bit field.

3.5.4.3 Wakeup

A wake-up event switches on two domains:

- A power domain (logic and associated memories) that is in inactive state
- A clock domain (including related clock sources, such as a DPLL)

If a domain is already on and the clock domain is idle, only the clocks are reactivated on a wake-up event.

To wake up, a processor requires an interrupt associated with the wake-up event. If its power domain is to transition from off or retention state to active, it must be reset.

There are three types of wake-up events:

- Global: Generated on a particular device event (device wakeup, voltage transition completed, DPLL recalibration, etc.). Used mainly to wake up the MPU domain
- Module: Functional wake-up event issued from a module, which wakes up the domain where the module resides. It can also directly wake up the MPU or the IVA2.2 processor, depending on software settings in the PRCM.PM_MPUGRPSEL_<power domain> and PRCM.PM_IVA2GRPSEL_<power domain> registers.
- Dependency: A power domain can wake up on the wakeup of another power domain. The dependency is software-controllable by configuring the PRCM.PM_WKDEP_<power domain> register.

3.5.4.4 Device Wake-Up Events

This section summarizes the wake-up events for each power domain. Table 3-63 through Table 3-73 list the wake-up events, related control registers, and MPU and IVA2.2 interrupts.

Two registers, PRCM.PRM_IRQENABLE_MPU and PRCM.PRM_IRQENABLE_IVA2, enable the MPU and IVA2.2 interrupts. In some cases, they can also enable the wake-up feature associated with the interrupt (DPLL recalibration requests, voltage controller and processors errors, and device wake-up event).

NOTE:

- The PRCM module can be configured to generate an interrupt to the MPU or the IVA2 subsystem as a result of a wake-up event from the CORE, WKUP, and PER power domain modules to the MPU and the IVA2. However, these modules can also directly interrupt the MPU and the IVA2 subsystems. To avoid a double interrupt (from the PRCM module and one of these modules) as the result of a single event (wakeup), one interrupt must be masked when the other is unmasked. For more information about the interrupt capability of a module, see the module chapter.
- The UART, GPIO, and McSPI modules generate an asynchronous wake-up event (their interface and functional clocks can be gated during the sleep period). However, because the GPTIMERs generate a synchronous wake-up event, they require their functional clock to be active during the sleep period; their interface clock can be gated. McBSP modules can generate a synchronous or asynchronous wake-up event, based on the mode configurations. For more information about the interrupt capability of a module, see the module chapter.
- The ability of a module to generate a wake-up event depends on the power state of the power domain in which the module resides. If the power domain is inactive (the functional and interface clocks of the domain are gated), only the asynchronous wake-up modules can wake up the power domain. If only the interface clocks in the domain are gated, synchronous and asynchronous wake-up modules can generate a wake-up event to activate the interface clock. Similarly, if the power domain is in retention or off power state (the domain logic is nonfunctional), no wake-up event can be generated by any module in that power domain.

Table 3-63. MPU Power Domain Wake-Up Events

Internal Wake-Up Events	Source Module	PRCM Software Control	Wake-Up Event	Interrupt/Type	Interrupt to
IVA2, CORE, DSS, and PER domain dependency	PRCM	PM_WKDEP_MPU	Yes	No	N/A

GPTIMER1 wakeup	GPTIMER1		Yes	No	N/A
GPIO1 wakeup	GPIO 1		Yes	No	N/A

NOTE: Some of the 32 I/O pins for the GPIO1 in the WKUP power domain are connected to the device I/O pad logic in the CORE power domain (VDD2) and to the reset to the device I/O pad logic in the WKUP power domain (VDD3). As a result, when the CORE power domain is off, the corresponding I/O pins of the GPIO1 cannot generate a wake-up event. For details, see Chapter 25, *General-Purpose Interface Module*.

3.5.4.5 Sleep and Wake-Up Dependencies

3.5.4.5.1 Sleep Dependencies

The (clock activity) dependencies between power domains are implemented to manage their sleep and wake-up transitions to ensure stable operation of the device.

A power domain sleep transition is achieved when all its clock domains (that is, functional and interface) are gated. For the gating of a clock domain, the following conditions must be satisfied:

- All initiator modules in the clock domain are in standby mode, that is, they cannot initiate any new transitions.
- All target modules in the clock domain are in idle mode and have no pending transitions.
- If the power domain depends on another power domain (that is, has a sleep dependency), the clock domains of the other power domain must be muted.

A clock domain is said to be muted when all its public initiator modules (that is, the initiator modules of the clock domain that can generate interconnect transactions towards targets outside the clock domain) are in standby mode, and the domain cannot initiate new interconnect transactions toward other domains.

Table 3-74 describes the mute conditions for the clock domains.

Table 3-74. Clock Domain Mute Conditions

Clock Domain Name	Clock Domain Composition	Mute Conditions
MPU	MPU power domain and MPU INTC in CORE power domain	MPU in stand-by, MPU INTC idle
IVA2	IVA2 power domain and WUGEN in CORE power domain	IVA2.2 in stand-by, WUGEN idle
SGX	SGX power domain	SGX in stand-by
CAM	CAM power domain	CAM in stand-by
DSS	DSS power domain	DSS in stand-by
PER	PER power domain	N/A (No public Initiator)
CORE_L3	L3 interconnect, L3 targets/initiators in CORE power domain	sDMA in standby
CORE_L4	L4 interconnect, L4 targets in CORE power domain	N/A (No public Initiator)
USBHOST	USBHOST power domain	USBHOST in stand-by
WKUP	WKUP power domain	N/A (No public Initiator)

A sleep dependency prevents the PRCM module from gating the clocks to a power domain (for sleep transition to inactive, retention, or off state from on state) if a dependent power domain is active (its clocks are active). A power domain can depend on several other power domains.

A power domain sleep dependency is programmed by setting the PRCM.CM_SLEEPDEP_<domain> register.

Example:

The PER domain has a programmable sleep dependency with the MPU and IVA2 power domains, and a hardwired sleep dependency with the CORE power domain. Therefore, if all software dependencies are enabled, the PER domain can go to idle mode only if the MPU, IVA2, and CORE-L3 clock domains are idle. If all software dependencies are disabled, the PER domain can go to idle mode, provided that the CORE-L3 clock domain is muted (no access to the PER domain can be pending).

Table 3-75 summarizes the programmable and hardwired sleep dependencies among the domains.

NOTE: The first row of the table identifies the dependent power domains for a power domain listed in the first column. Therefore, to identify the sleep dependency of power domain X, identify domain X in the first column, then follow its row to its sleep dependency with another power domain (identified in the top row).

Table 3-75. Sleep Dependencies

		Sleep Dependency											
Power Domain	**Clock Domain**	**MPU**	**NEON**	**IVA2**	**SGX**	**CAM**	**DSS**	**PER**	**CORE_ L3**	**CORE_ L4**	**CORE_ CM**	**USB HOST**	**WKUP**
MPU	MPU	n/a	0	0	0	0	0	0	0	0	0	0	0

WKUP	WKUP	1	0	1	0	0	0	0	1	0	0	0	n/a

Notes:

No software control (hardwired values):	0	Does not depend on
	1	Depends on
Software controllable	RW	Read and write
	n/a	Not applicable

3.5.4.5.2 Wake-Up Dependencies

A wake-up dependency allows a power domain to wake up (from off, retention or inactive state to on state) when another power domain wakes up (from off, retention or inactive state to on state). For example, power domain one (PD1) provides a service to power domain two (PD2), which creates a dependency between the two domains. When the dependent power domain (PD2) wakes up, it signals PD1 with a broadcasted wake-up event, causing PD1 to wake up.

A broadcasted wake-up event can originate from one of two sources:

- PD2 internal wake-up event (typically, a peripheral wake-up event)
- Abortion of the mute mode (at least one initiator in the domain exits standby mode) of PD2 when both the sleep dependency and wake-up dependency with PD1 are enabled.

NOTE: The domain wake-up dependency is a non-transitive property.

If a power domain PD1 has wake-up dependency with power domain PD2, i.e., PRCM.PM_WKDEP_PD1. EN_PD2 bit is set to 1 and if PD2 has wake-up dependency with power domain PD3, i.e., PRCM.PM_WKDEP_PD2. EN_PD3 bit is set to 1.

However, if PD1does not have a direct wake-up dependency with PD3, i.e., PRCM.PM_WKDEP_PD1. EN_PD3 bit is set to 0. Then if the PD1 and PD2 are in inactive/retention or off power state and PD3 is inactive and is woken-up by a wake-up event, the PD2 is also woken-up but not the PD1.

Because a power domain can depend on several other power domains, it can broadcast the wake-up signal to each power domain on which it depends.

A power domain wake-up dependency can either be hardwired (set in the hardware) or programmable through software by configuring the PM_WKDEP_<domain> register for that power domain. Continuing the example of PD2 as dependent on PD1, setting the PM_WKDEP_PD1.PD2 bit means that when PD2 wakes up, PD1 also wakes up.

The MPU power domain can be wakened only by the IVA2, DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP power domains. Similarly, the IVA2 power domain can be wakened only by the MPU, DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP power domains. All wake-up dependencies of the MPU and the IVA2 power domain are software-configurable.

For the processor power domains (MPU and the IVA2 power domain), when the wake-up dependency with other power domains is software-programmable (that is, with the USBHOST, PER, CORE, and WKUP power domains), two registers may need be configured: PM_WKDEP_<domain> and PM_<processor>GROUPSEL_<domain>.

The PM_WKDEP_<domain> register serves only to enable/disable the global wake-up dependency of the processor power domain on these three power domains. The PM_<processor>GROUPSEL_<domain> register must be configured to enable the particular wake-up event in these domains that will wake up the processor domain. Thus, the global wake-up dependency for a dependent domain must be enabled so that a wake-up event can occur, if it has been enabled in the corresponding GROUPSEL register.

For example, if the wake-up dependency of the MPU power domain is to be enabled for a wake-up event from the GPIO2 module of the PER power domain, the following configuration is required:

- PRCM.PM_MPUGRPSEL_PER[13] GRPSEL_GPIO2
- PRCM.PM_WKDEP_MPU[7] EN_PER

Table 3-76 summarizes the programmable and hardwired wake-up dependencies among the domains.

Table 3-76. Wake-Up Dependencies

		Wake-Up Dependency											
Power Domain	**Clock Domain**	**MPU**	**NEON**	**IVA2**	**SGX**	**CAM**	**DSS**	**USB HOST**	**PER**	**CORE_ L3**	**CORE_ L4**	**CORE_ CM**	**WKUP**

1	Hardware wakeup dependency: dependency always enabled
0	No wakeup dependency applicable

3.5.4.6 USBHOST/USBTLL Save-and-Restore Management

Both USBHOST and USBTLL support a save-and-restore mechanism. When the device enters into off mode (that is, all power domains, except the WKUP power domain, are off), the user may want to save the USBHOST context and restore it when exiting off mode. The save-and-restore mechanism for the HS USB Host is enabled by setting the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit; for the USBTLL, it is configured by the PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit. The save mechanism is initiated as the power domain transitions from active to off state (or to OSWR state for the USBTLL), whereas the restore mechanism is initiated as the power domain transitions from off to active power state.

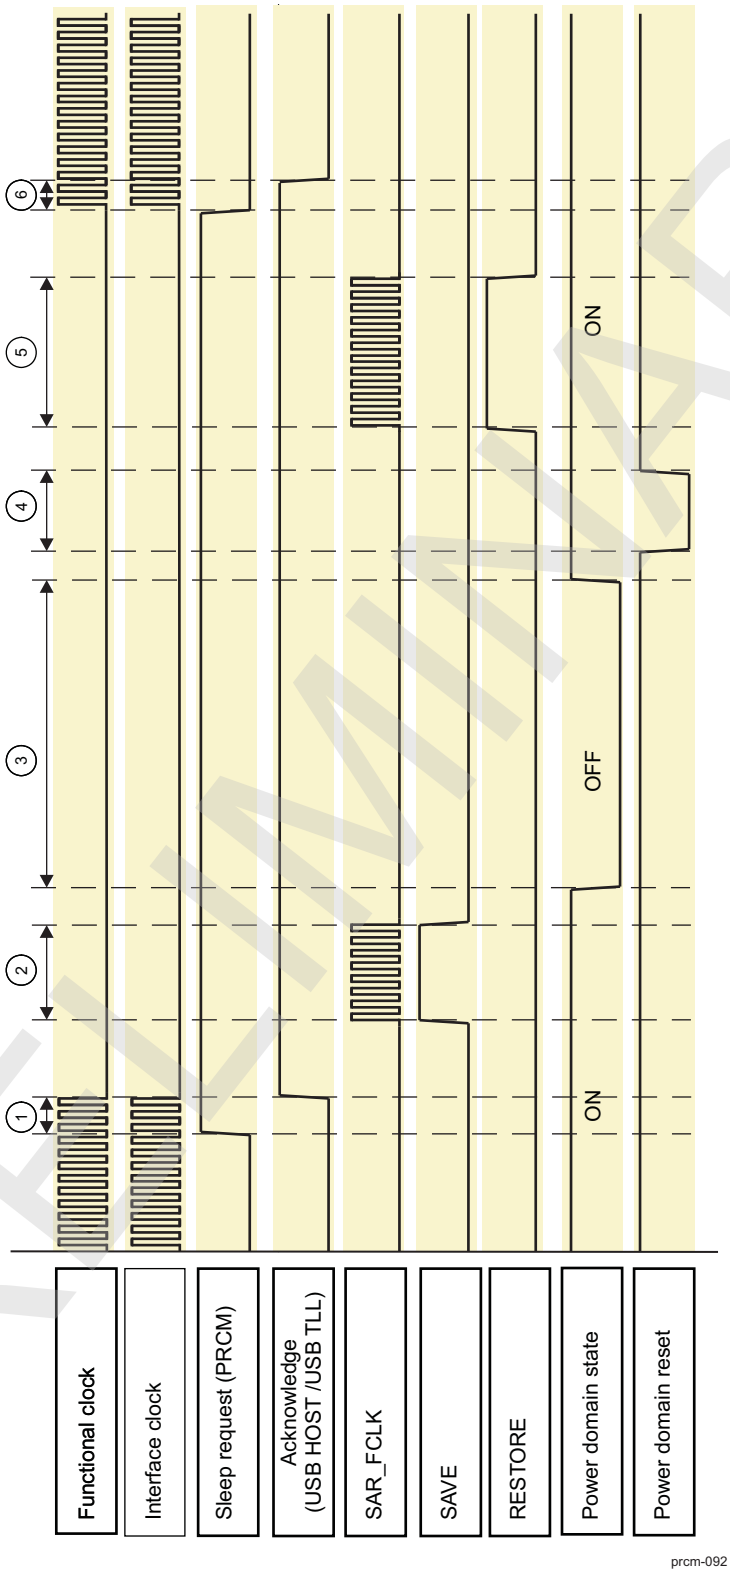
Figure 3-77 shows the generic save-and-restore sequence applicable to both the USBHOST and the USBTLL. The sequence follows:

1. When the PRCM module intends to initiate a sleep transition over the power domain (the USBHOST power domain for the HS USB Host subsystem and the CORE power domain for the USBTLL module), it sends a sleep request to the power domain. When the domain modules acknowledge the sleep request, the functional and interface clocks to the modules are gated.
2. The PRCM module enables the SAR_FCLK functional clock and initiates the save sequence for the module. SAR_FCLK is gated when the save sequence completes.
3. The PRCM module switches the power domain state to off power state. When a wake-up event occurs, the PRCM module switches on the power domain.
4. The power domain local reset is asserted and then released by the reset manager.
5. The PRCM module enables the SAR_FCLK functional clock, and then initiates the restore sequence for the module. SAR_FCLK is gated when the restore sequence completes.
6. The PRCM module enables the functional and interface clocks to the modules and releases the sleep request. The modules acknowledge, and the wake-up sequence completes.

NOTE: The PRCM sleep request and the module acknowledge signals are part of a hardware communication interface to ensure the correct sleep and wake-up sequence.

Figure 3-77 shows the save-and-restore sequence. It does not provide the exact timing delays between the switching of the signals and serves only to highlight the sequence of events.

Figure 3-77. Save-and-Restore Sequence



3.5.4.6.1 USBHOST SAR Sequences

3.5.4.6.1.1 Save Sequence on Sleep Transition

A precondition to the save sequence on sleep transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from ON to OFF power state.

1. The PRCM module activates USBHOST_SAR_FCLK and starts the save sequence.
2. When the USBHOST power domain is idled (all clocks of the power domain are gated), the PRM initiates the power domain transition to OFF power state by setting the PRCM.PM_PWSTCTRL_USBHOST[1:0] POWERSTATE bit field to 0x0.
3. When the save sequence completes, USBHOST_SAR_FCLK is gated.
4. The power domain sleep transition to OFF power state completes.

3.5.4.6.1.2 Restore Sequence on Wake-Up Transition

A precondition to the restore sequence on wake-up transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from off to on power state.

1. The PRCM switches the power domain to ON power state.
2. The PRCM asserts the USBHOST domain reset. The functional reset is released locally when the functional clocks are back.
3. The PRCM releases the USBHOST domain reset.
4. The PRCM module activates USBHOST_SAR_FCLK and starts the restore sequence.
5. When the restore sequence completes, USBHOST_SAR_FCLK is gated.
6. The power domain wake-up transition to ON power state completes.

3.5.4.6.2 USB TLL SAR Sequences

3.5.4.6.2.1 Save Sequence on Sleep Transition

A precondition to the save sequence on sleep transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from ON to Open Switch Retention (OSWR) or OFF power state.

1. When the CORE power domain is idled (all clocks of the power domain are gated), the PRM initiates the power domain transition to OFF or OSWR power state by setting the PRCM.PM_PWSTCTRL_CORE[1:0] POWERSTATE bit field to 0x0 or 0x1.
2. The PRCM module activates USBTTL_SAR_FCLK and starts the save sequence.
3. When the save sequence completes, USBTTL_SAR_FCLK is gated.
4. The power domain sleep transition to OFF or OSWR power state completes.

3.5.4.6.2.2 Restore Sequence on Wake-Up Transition

A precondition to the restore sequence on wake-up transition is that the save-and-restore mechanism is enabled (the PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit is set to 1). The sequence is initiated when the power domain switches from OFF or OSWR to ON power state.

1. 1. PRCM switches the power domain to ON power state.
2. Assert CORE domain reset (must override the functional stall conditions of the reset manager). The functional reset is released locally when the functional clocks are back.
3. Release CORE domain reset.
4. The PRCM module activates the USBTLL_SAR_FCLK and starts the restore sequence.
5. When the restore sequence completes, USBTLL_SAR_FCLK is gated.
6. The power domain wake-up transition to ON power state completes.

3.5.5 PRCM Interrupts

Table 3-77 lists the interrupts from the PRCM module to the MPU and the IVA2.

Table 3-77. Interrupt Descriptions

Interrupt Name	Mapping	Description
PRCM_MPU_IRQ	M_IRQ_11	To MPU interrupt controller (MPU INTC)
PRCM_IVA_IRQ	IVA2_IRQ[12]	To IVA2.2 wake-up controller (IVA2.2 WUGEN)

Table 3-78 and Table 3-79 summarize the event flags (in PRM_IRQSTATUS_MPU and PRM_IRQSTATUS_IVA2 registers) and mask (in PRM_IRQENABLE_MPU and PRM_IRQENABLE_IVA2 registers) related to the events generating PRCM interrupts to the MPU and the IVA2.

Table 3-78. MPU Interrupt Event Descriptions

Event Flag	Event Mask	Map to	Automatic MPU Domain Wake-Up Event	Description
PRM_IRQSTATUS_MPU[0] WKUP_ST	PRM_IRQENABLE_MPU[0] WKUP_EN	PRCM_MPU_IRQ	No	MPU peripheral group wakeup
PRM_IRQSTATUS_MPU[2] EVGENON_ST	PRM_IRQENABLE_MPU[2] EVGENON_EN	PRCM_MPU_IRQ	No	Event generator end of on time
PRM_IRQSTATUS_MPU[3] EVGENOFF_ST	PRM_IRQENABLE_MPU[3] EVGENOFF_EN	PRCM_MPU_IRQ	No	Event generator end of off time
PRM_IRQSTATUS_MPU[4] TRANSITION_ST	PRM_IRQENABLE_MPU[4] TRANSITION_EN	PRCM_MPU_IRQ	No	A sleep or wake-up transition completion event for IVA2, NEON, SGX, DSS, CAM, PER, EMU, USBHOST power domains
PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST	PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL3 recalibration event
PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST	PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL4 recalibration event
PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST	PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL2 recalibration event
PRM_IRQSTATUS_MPU[8] IVA2_DPLL_ST	PRM_IRQENABLE_MPU[8] IVA2_DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL1 recalibration event
PRM_IRQSTATUS_MPU[9] IO_ST	PRM_IRQENABLE_MPU[9] IO_EN	PRCM_MPU_IRQ	No	I/O pads wake-up event
PRM_IRQSTATUS_MPU[10] VP1_OPPCHANGEDONE_ST	PRM_IRQENABLE_MPU[10] VP1_OPPCHANGEDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 1 OPP change done event.
PRM_IRQSTATUS_MPU[11] VP1_MINVDD_ST	PRM_IRQENABLE_MPU[11] VP1_MINVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 1 new voltage reached the minimum voltage value allowed.
PRM_IRQSTATUS_MPU[12] VP1_MAXVDD_ST	PRM_IRQENABLE_MPU[12] VP1_MAXVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 1 new voltage reached the maximum voltage value allowed.
PRM_IRQSTATUS_MPU[13] VP1_NOSMPSACK_ST	PRM_IRQENABLE_MPU[13] VP1_NOSMPSACK_EN	PRCM_MPU_IRQ	No	Voltage processor 1 time-out occurred while waiting for the power IC device acknowledge.
PRM_IRQSTATUS_MPU[14] VP1_EQVALUE_ST	PRM_IRQENABLE_MPU[14] VP1_EQVALUE_EN	PRCM_MPU_IRQ	No	Voltage processor 1 new voltage is the same as the current voltage.

Table 3-78. MPU Interrupt Event Descriptions (continued)

Event Flag	Event Mask	Map to	Automatic MPU Domain Wake-Up Event	Description
PRM_IRQSTATUS_ MPU[15] VP1_ TRANXDONE_ST	PRM_IRQENABLE_ MPU[15] VP1_ TRANXDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 1 transaction is complete.
PRM_IRQSTATUS_ MPU[16] VP2_ OPPCHANGEDONE_ST	PRM_IRQENABLE_ MPU[16] VP2_ OPPCHANGEDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 OPP change done event.
PRM_IRQSTATUS_ MPU[17] VP2_ MINVDD_ST	PRM_IRQENABLE_ MPU[17] VP2_ MINVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage reached the minimum voltage value allowed.
PRM_IRQSTATUS_ MPU[18] VP2_ MAXVDD_ST	PRM_IRQENABLE_ MPU[18] VP2_ MAXVDD_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage reached the maximum voltage value allowed.
PRM_IRQSTATUS_ MPU[19] VP2_ NOSMPSACK_ST	PRM_IRQENABLE_ MPU[19] VP2_ NOSMPSACK_EN	PRCM_MPU_IRQ	No	Voltage processor 2 time-out occurred while waiting for the power IC device acknowledge.
PRM_IRQSTATUS_ MPU[20] VP2_ EQVALUE_ST	PRM_IRQENABLE_ MPU[20] VP2_ EQVALUE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 new voltage is the same as the current voltage.
PRM_IRQSTATUS_ MPU[21] VP2_ TRANXDONE_ST	PRM_IRQENABLE_ MPU[21] VP2_ TRANXDONE_EN	PRCM_MPU_IRQ	No	Voltage processor 2 transaction is done.
PRM_IRQSTATUS_ MPU[22] VC_ SAERR_ST	PRM_IRQENABLE_ MPU[22] VC_ SAERR_EN	PRCM_MPU_IRQ	Yes	Slave address in an I^2C frame sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_ MPU[23] VC_ RAERR_ST	PRM_IRQENABLE_ MPU[23] VC_ RAERR_EN	PRCM_MPU_IRQ	Yes	Register address in an I^2C frame sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_ MPU[24] VC_ TIMEOUTERR_ST	PRM_IRQENABLE_ MPU[24] VC_ TIMEOUTERR_EN	PRCM_MPU_IRQ	Yes	Last byte of an I^2C frame issued from the bypass port or from the voltage manager FSM ports sent by the voltage controller not acknowledged by the power IC device
PRM_IRQSTATUS_ MPU[25] SND_PERIPH_ DPLL_RECAL_ST	PRM_IRQENABLE_ MPU[25] SND_PERIPH_ DPLL_RECAL_EN	PRCM_MPU_IRQ	Yes	DPLL5 recalibration event
PRM_IRQSTATUS_ MPU[26] ABB_LDO_ TRANXDONE_ST	PRM_IRQENABLE_ MPU[26] ABB_LDO_ TRANXDONE_EN	PRCM_MPU_IRQ	No	ABB LDO transaction completion status. This status is set when a software-initiated transaction is completed in ABB LDO (active mode transition only).
PRM_IRQSTATUS_ MPU[27] VC_VP1 _ACK_ST	PRM_IRQENABLE_ MPU[27] VC_VP1_ ACK_EN	PRCM_MPU_IRQ	No	Voltage controller's acknowledge to the VDD1 voltage processor status
PRM_IRQSTATUS_ MPU[28] VC_BYPASS_ ACK_ST	PRM_IRQENABLE_ MPU[28] VC_BYPASS_ ACK_EN	PRCM_MPU_IRQ	No	Voltage controller's acknowledge to the bypass interface status

NOTE: TRANXDONE and OPPCHANGEDONE interrupt events are generated under the same conditions (after voltage change).

Table 3-79. IVA2 Interrupt Event Descriptions

Event Flag	Event Mask	Map to	IVA2 Domain Wake-Up Event	Description
PRM_IRQSTATUS_IVA2[0] WKUP_ST	PRM_IRQENABLE_IVA2[0] WKUP_EN	PRCM_IVA_IRQ	No	IVA2 peripheral group wakeup
PRM_IRQSTATUS_IVA2[1] FORCEWKUP_ST	PRM_IRQENABLE_IVA2[1] FORCEWKUP_EN	PRCM_IVA_IRQ	No	IVA2 power domain forced wake-up transition completion
PRM_IRQSTATUS_IVA2[2] IVA2_DPLL_ST	PRM_IRQENABLE_IVA2[2] IVA2_DPLL_RECAL_EN	PRCM_IVA_IRQ	Yes	DPLL2 recalibration required

NOTE: The software must first read the event flag to determine the cause of the interrupt and then write 1 to it to clear the flag.

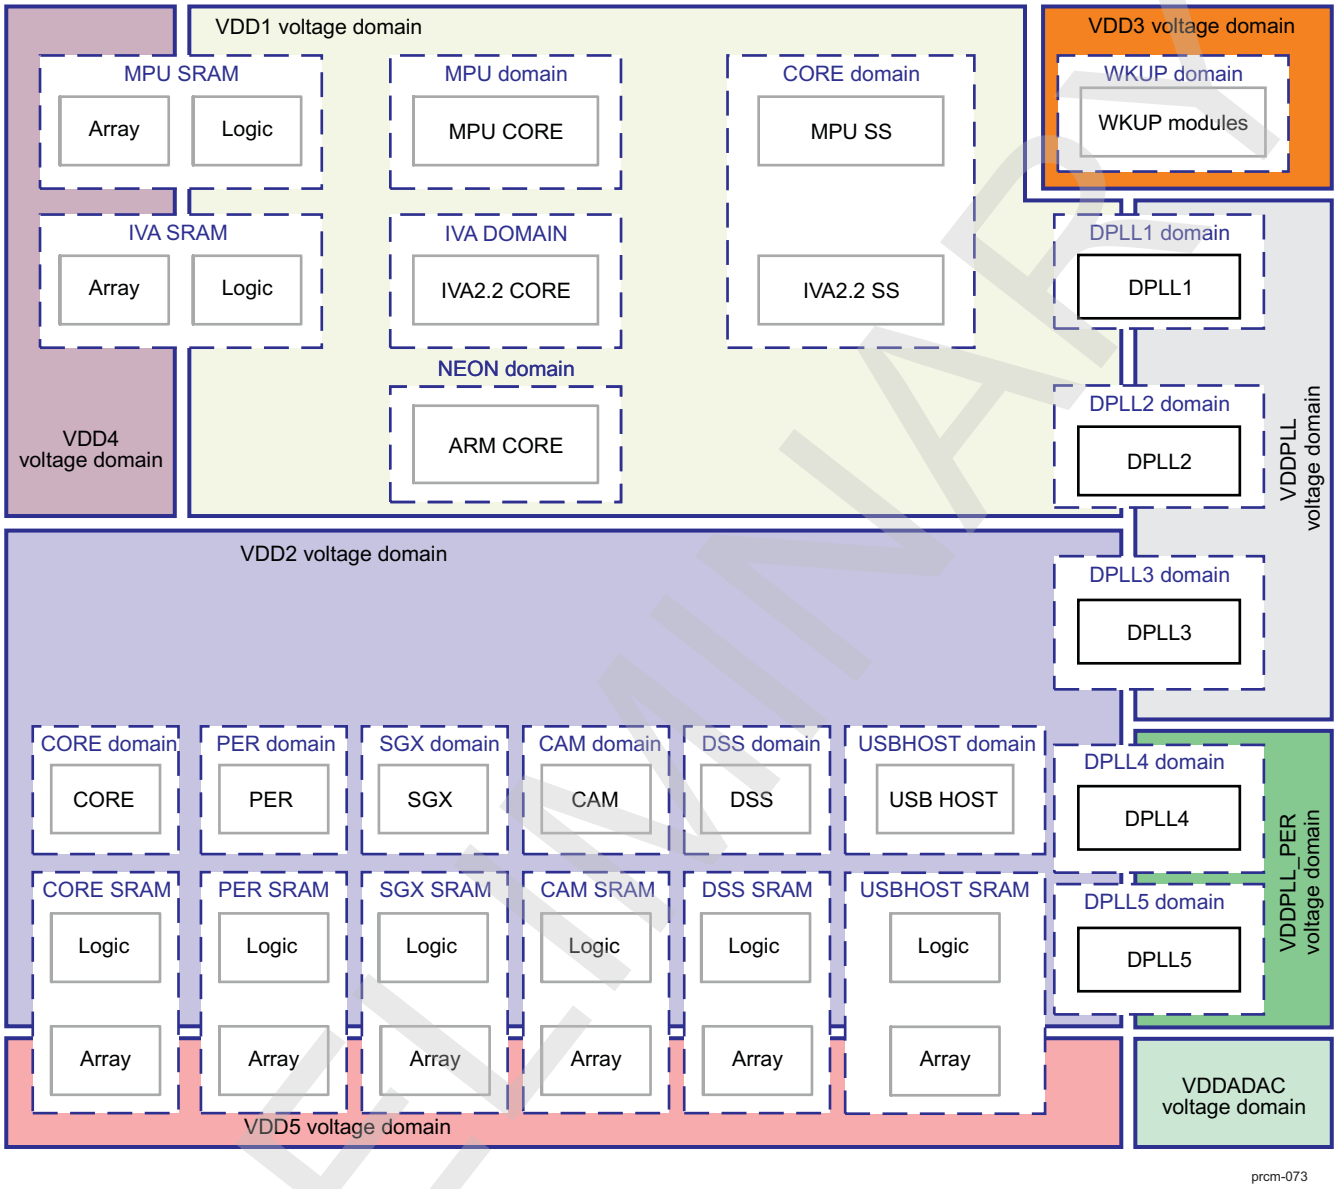
3.5.6 PRCM Voltage Management Functional Description

This section describes the voltage domains and voltage control architecture. It also explains the interactions between the device and the external power IC.

3.5.6.1 Overview

Figure 3-78 is an overview of the device voltage domains.

Figure 3-78. Overview of Device Voltage Domains



The device is split into voltage domains:

- Three voltage domains for logic (VDD1, VDD2, and VDD3)
- Two voltage domains for memory (VDD4 and VDD5)
- Two voltage domains for PLLs and analog cells (VDDPLL and VDDPLL_PER)
- Voltage domain for the I/Os

This partition of the voltage domains ensures independent voltage control of each voltage domain through dedicated SMPS or LDO. Functionally, however, voltage control of a voltage domain may depend on the voltage level of another voltage domain; for example, VDD1 voltage-level control may depend on the VDD2 voltage level. Figure 3-78 shows the voltage dependency between domains.

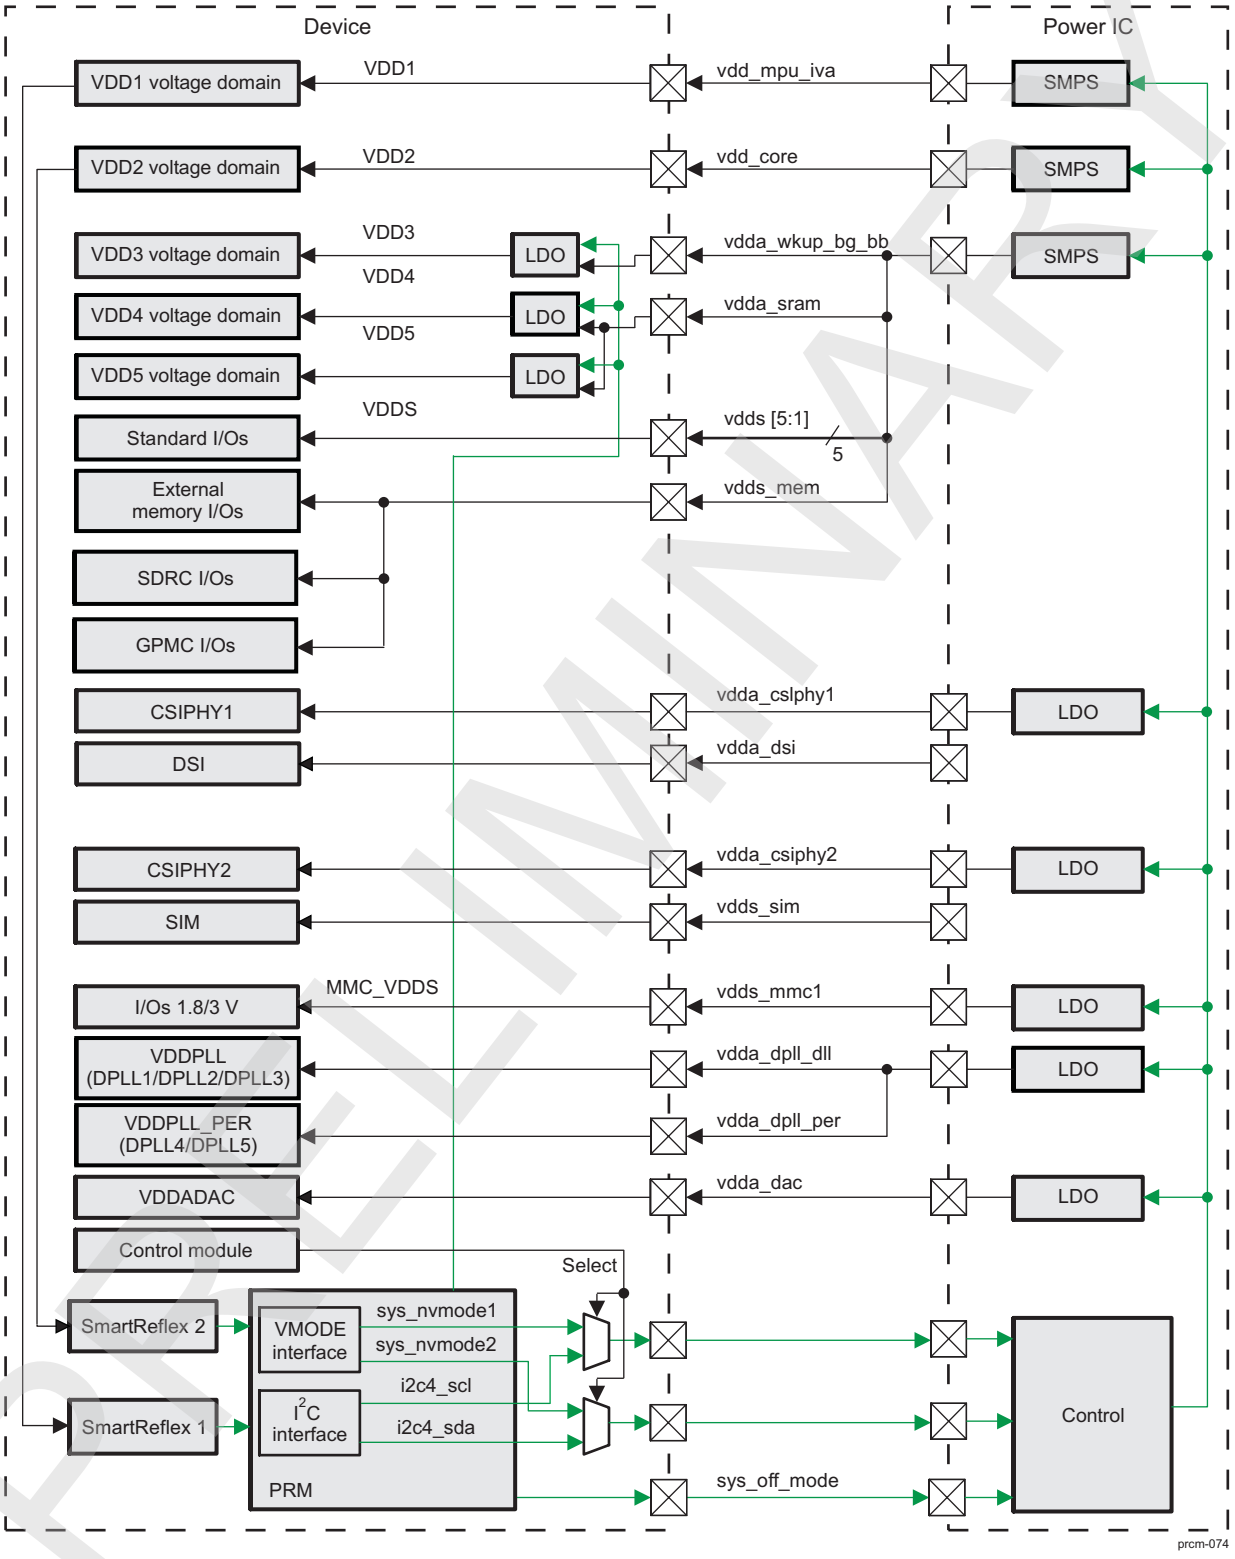
Figure 3-79 is an overview of the device voltage sources and their controls. The PRM directly manages the following voltage sources:

- VDD1: Processor voltage
- VDD2: CORE voltage
- VDD3: Wake-up voltage

- VDD4: Processor SRAM voltage
- VDD5: CORE SRAM voltage

The remaining voltage sources (VDDS, VDDPLL, and MMC-VDDS) are either controlled directly by the external device or software-controlled through an I^2C interface independent of the PRM. Figure 3-79 is an overview of PRCM voltage control.

Figure 3-79. Overview of Device Voltage Distribution



NOTE: Memory I/Os (1.8 V) are not supplied with the other I/Os. They come directly from the power IC.

3.5.6.2 Voltage Domains

Table 3-80 summarizes, for each voltage domain, the voltage level corresponding to its OPP when its power domains are on and the voltage level when its power domains are in retention or off power state. The exact values depend on the silicon.

Table 3-80. Voltage Domain Controls Summary

Voltage Domain (Power Rail)	Operating Point	Control	Supplied Modules
VDD1 voltage domain (vdd_mpu_iva)	Off	HW and SW	MPU subsystem, IVA2.2 subsystem, digital part of DPLL1 and DPLL2, SmartReflex1
	Retention		
	OPP50		
	OPP100		
	OPP130		
	OPP1G		
VDD2 voltage domain (vdd_core)	Off	HW and SW	Most modules, interconnects, peripherals. SmartReflex2, digital part of DPLL3, DPLL4, and DPLL5
	Retention		
	OPP50		
	OPP100		
VDD3 voltage domain (vdda_wkup_bg_bb)	Low-power mode	HW	WKUP and EMU domains
	Normal mode		
	Emulation mode		
VDD4 voltage domain (vdda_sram)	All memories off	HW	Processor memories
	All memories in retention		
	VDD1 is in OPP50, or OPP100		
	VDD1 in OPP130		
VDD5 voltage domain (vdda_sram)	Off	HW	CORE, SGX, CAM, DSS, PER, USBHOST, and EMU memories
	Retention		
	VDD2 is in OPP50, or OPP100		
VDDS voltage domain (vdds)	Always-on	None	I/Os
VDDADAC voltage domain (vdda_dac)	Software-driven only(1)	SW	Video DAC
VDDPLL voltage domain (vdda_dpll_dll)	Always-on(1)	None	Analog part of DPLL1, DPLL2, and DPLL3
VDDPLL_PER voltage domain (vdda_dpll_per)	Always-on(1)	None	Analog part of DPLL4 and DPLL5
External memory I/Os (vdds_mem)	Always-on (1)	None	External memory, SDRC, and GPMC I/Os
CSIPHY1 (vdda_csiphy1)	Always-on(1)	None	CAM balls
DSI (vdda_dsi)	Always-on(1)	None	DSI balls
CSIPHY2 (vdda_csiphy2)	Always-on(1)	None	CSI2 balls
SIM (vdds_sim)	Always-on(1)	None	SIM
MMC_VDDS voltage domain (vdds_mmc1)	Always-on(1)	None	MMC1

(1) Identifies voltage domains that can be switched to 0.0 V when the interface/module is not in use.

NOTE:

- Full device logic retention is also feasible by keeping all power domains on and lowering VDD1 and VDD2 to minimum OPP (CSWR). This consumes more power than the first option, but allows for a fast restart.
- When the user programs all memories in retention, VDD4 and VDD5 are automatically set to RETENTION voltage level by the PRM, which allows the memory arrays to be retained.

3.5.6.3 Voltage Domain Dependencies

Table 3-81 and Table 3-82 summarize the hardware conditions and the software setting required to switch the VDD1 and VDD2 to their respective low-power states.

Table 3-81. VDD1 Voltage Domain Dependencies

VDD1 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD2	VDD3	VDD4	VDD5
SLEEP	Software controlled power domains of VDD1 are in inactive, retention, or off state.	DPLL1 and DPLL2 are in Stop mode.	N/A	AUTO_SLEEP = 1 AUTO_RET = 0 AUTO_OFF = 0	ON or SLEEP	ON or Overdriven	ON or retention	ON or retention
Retention	Software controlled power domains of VDD1 are in retention or off state and of VDD2 are in INACTIVE, retention or off state.	DPLL1 and DPLL2 are in Stop mode.	N/A	AUTO_SLEEP = 0 AUTO_RET = 1 AUTO_OFF = 0	ON or retention	ON or Overdriven	Retention	ON or retention
Off	Software controllable power domains of VDD1 and VDD2 are in off state.	All DPLLs are in Stop mode.	No longer required	AUTO_SLEEP = 0 AUTO_RET = 0 AUTO_OFF = 1	Off	SLEEP	Off	Off

NOTE: It is mandatory to program the three bit fields AUTO_SLEEP, AUTO_RET, and AUTO_OFF in an exclusive manner.

Table 3-82. VDD2 Voltage Domain Dependencies

VDD2 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD1	VDD3	VDD4	VDD5
SLEEP	Software controlled power domains of VDD1 and VDD2 are in inactive, retention or off state.	All DPLLs are in Stop mode.	No longer required	AUTO_SLEEP = 1 AUTO_RET = 0 AUTO_OFF = 0	SLEEP	ON or Overdriven	ON or retention	ON or retention

Table 3-82. VDD2 Voltage Domain Dependencies (continued)

VDD2 Domain State	Power Domains State	DPLL State	sys_clk	Software Control	VDD1	VDD3	VDD4	VDD5
Retention	Software controlled power domains of VDD1 are in inactive, retention or off state and of VDD2 are in retention or off state.	All DPLLs are in Stop mode.	No longer required	AUTO_SLEEP = 0 AUTO_RET = 1 AUTO_OFF = 0	ON or retention	ON or Overdriven	ON or retention	Retention
Off	Software controllable power domains of VDD1 and VDD2 are in off state.	All DPLLs are in Stop mode.	No longer required	AUTO_SLEEP = 0 AUTO_RET = 0 AUTO_OFF = 1	Off	SLEEP	Off	Off

NOTE:

- In voltage domain SLEEP state, the current load decreases because of reduced activity level; however, the voltage level remains that of on state.
- In voltage domain overdriven state, the domain voltage is raised above the nominal operating voltage to boost performance; however, power consumption also increases.
- AUTO_SLEEP, AUTO_RET and AUTO_OFF, in the Software Control column, refer to the PRM_VOLTCTRL[0] AUTO_SLEEP, PRM_VOLTCTRL[1] AUTO_RET and PRM_VOLTCTRL[2] AUTO_OFF bits.

Table 3-83. Remaining Voltage Domain Dependencies

Voltage	Condition
VDDS	No dependency with other device voltages
External memory I/Os	
VDDADAC	
VDDPLL	
VDDPLL_PER	
CSIB	
DSI	
CSIPHY2	
SIM	
MMC_VDDS	

3.5.6.4 Voltage-Control Architecture

The PRM is split over several blocks that manage the different voltage sources.

- VDD1 and VDD2 voltages are managed by multiple control sources:
  - Automatic voltage adjustment (for optimal performance at an OPP) and software-requested voltage scaling (for OPP change) are managed by two SmartReflex voltage control modules connected to two voltage processor modules. They generate voltage-adjustment commands based on the desired and current performance levels of the device. These commands are sent to the external power IC through a voltage controller and a dedicated I^2C interface.
  - Direct software control of VDD1 and VDD2 is also possible by writing to the registers of the voltage controller, which then sends the voltage commands to the power IC through the dedicated I^2C

interface.

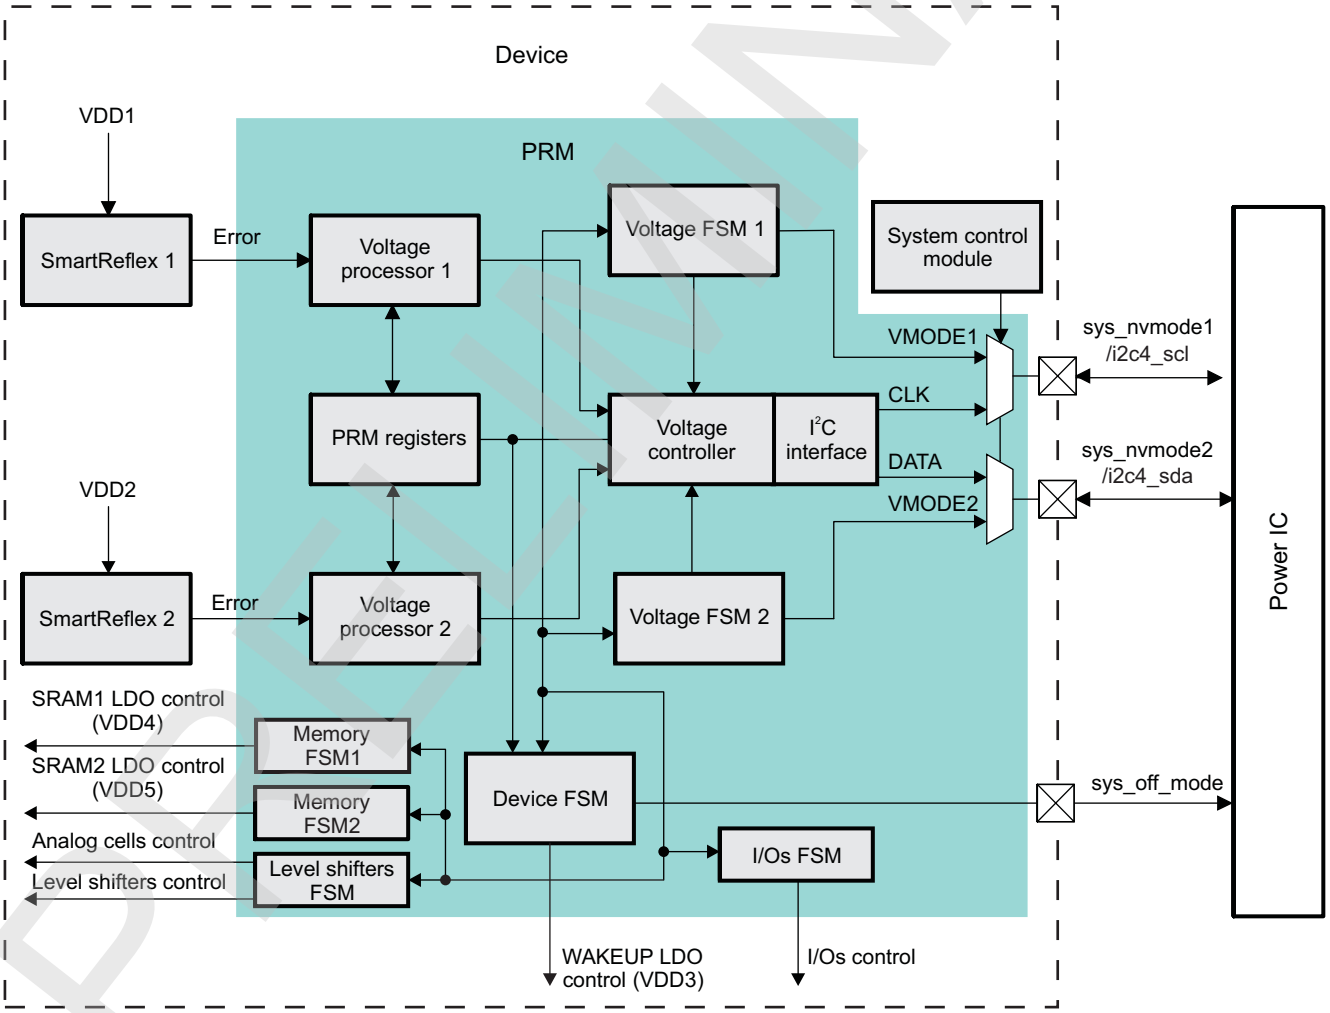
– Two voltage finite state-machines (FSM 1 and FSM 2) can also manage the VDD1 and VDD2 voltages either by sending commands to the voltage controller (I^2C mode) or by sending the sys_nvmode1 and sys_nvmode2 control signals (direct-control mode). The FSMs control voltage-level switching, based on the power state of the device.

- The FSMs in the PRM also control SRAM and wake-up LDOs, sleep mode for analog cells, and level shifters.
- A device FSM sequences the memory, wakeup, voltage, and I/O FSMs during the device off, sleep, and wake-up transitions.

NOTE: The SmartReflex module allows dynamic voltage adjustments around an OPP voltage level to ensure target performance. It also allows switching from one OPP to another. However, it does not control voltage switching to retention or off as the power domains or the device change power states. This is handled by the voltage FSMs.

Figure 3-80 shows the architecture for PRM voltage control.

Figure 3-80. PRM Voltage Control Architecture



* The green region in the figure represents the boundary of the PRM.

prcm-075

CAUTION

It is highly recommended to use the embedded dedicated I2C4 instead of VMODE, which is a legacy mode. The I2C4 provides greater flexibility and higher efficiency in terms of power optimization.

3.5.6.5 VDD1 and VDD2 Control

The main power-supply sources, VDD1 and VDD2, can be controlled using mutually exclusive modes specified in the SCM:

- Direct control with VMODE signals or I2C interface
- Dedicated SmartReflex I^2C control

Because both control modes are multiplexed on the same device pins, direct control signals can be used alternately with I^2C control signals. The muxes are managed by the SCM.

3.5.6.5.1 Direct Control With VMODE Signals

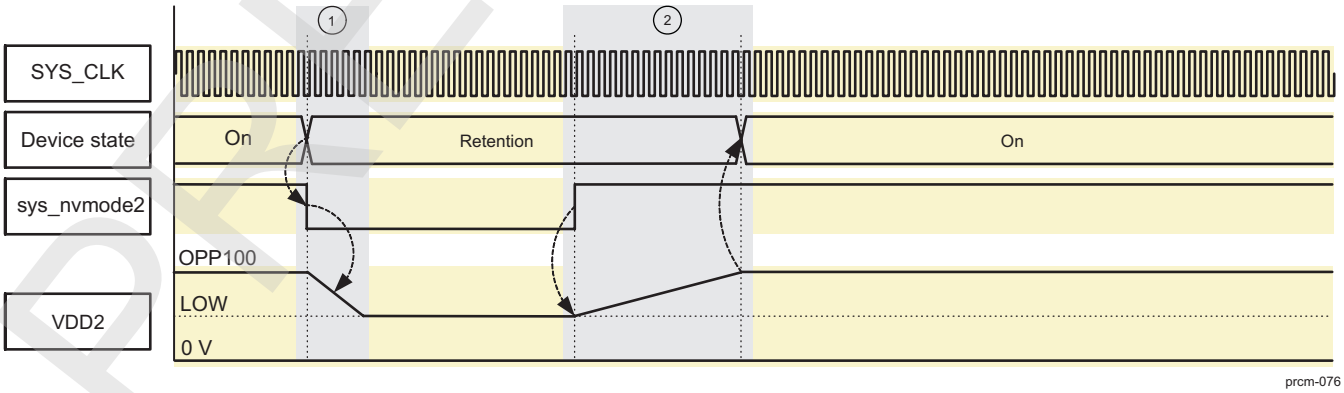
In direct-control mode, the VDD1 and VDD2 voltage sources can be controlled by the voltage FSMs in the PRM to trigger a voltage transition based on the power domain states. The voltage FSMs use a VMODE interface to send voltage commands through the sys_nvmode1 and sys_nvmode2 pins of the device to the external power IC. The simple voltage-control commands of the VMODE interface can be used to set two voltage values (VDD1 and VDD2) per voltage domain .

The sys_nvmode[1,2] signals request new voltage levels to the external SMPS. The polarity of the sys_nvmode[1,2] signals from the PRM is configured by the PRCM.PRM_POLCTRL[0] EXTVOL_POL bit, which is active-low by default. When the signal goes low, a lower voltage is supplied, and when it goes high, a higher voltage is supplied.

The VMODE voltage control is enabled by setting the PRM.PRM_VOLTCTRL[4] SEL_VMODE bit, and is triggered when the device switches between low-power (retention or off) mode and normal (on) mode.

Figure 3-81 is an example of a VDD2 voltage transition from an operational voltage (OPP100) to the lowest functional voltage of the device (LOW). In this example, the PRCM module is programmed to automatically lower sys_nvmode2 when the device enters sleep mode. The power IC is programmed to ramp the VDD2 voltage down to LOW when sys_nvmode2 is deasserted and to ramp up the voltage to OPP100 when sys_nvmode2 is asserted. The PRCM module must also wait for the VDD2 regulator to stabilize when sys_nvmode2 is deasserted and asserted. This stabilization time is programmable by software using the PRCM.PRM_VOLTSETUP1 register.

Figure 3-81. Voltage Transition Controlled by sys_nvmode2



Internally, the PRM manipulates two logical voltage levels (L0 and L1) for each sys_nvmode[1,2] signal. One level is set when all the power domains in the voltage domain are in retention or off mode, while the other is set when a power domain is on. The power IC must be configured to switch to low voltage when the associated sys_nvmode[1,2] signal is received, and vice versa.

For example, if L0 is the lower voltage and an active-low polarity (default setting) on the sys_nvmode[1,2] signal:

- L0 logical level sys_nvmode[1,2] = 1 VDD = OPP100
- L1 logical level sys_nvmode[1,2] = 0 VDD = LOW

The polarity of the logical voltage-level signal from the PRM can be controlled by the PRCM.PRM_POLCTRL[0] EXTVOL_POL bit. It is active-low by default (L0 = 1, L1 = 0).

3.5.6.5.2 Direct Voltage Control With I²C Interface

PRM can send VDD1 and VDD2 sleep commands to the power IC through the dedicated I²C. This allows the power IC to activate sleep mode (the voltage regulator switches in sleep mode, where voltage is maintained but only small load is supported). This also allows external power IC to reduce its power consumption.

3.5.6.5.3 Voltage Controller and Dedicated SmartReflex I²C Interface

The dedicated I²C voltage control mode is dedicated to SmartReflex technology. The central modules for the I²C control mode are the voltage controller and the I²C interface. The voltage controller receives voltage control commands from five input ports:

- Voltage processor 1 and 2 ports: The voltage processors send commands to the voltage controller depending on the SmartReflex module calculations (during device activity).
- Voltage FSM 1 and 2 ports: The voltage FSMs send commands to the voltage controller when the device enters retention or off power state, and also when the device wakes up.
- PRM register port: The PRM registers give direct software control over the voltage levels of the VDD1 and VDD2 voltage domains.

An arbitration scheme in the voltage controller manages concurrent requests on multiple ports.

Externally, the voltage controller interfaces to a power IC through a dedicated I²C interface (I2C4). To reduce the latency of voltage changes, the voltage controller is configurable to run in HS I²C mode.

Each internal port has a handshake to indicate when the I²C frame that results from the request on that port is acknowledged by the external power IC.

3.5.6.5.4 SmartReflex Voltage Control

As explained previously (see Section 3.1.2.2, *SmartReflex Adaptive Voltage Scaling*), SmartReflex technology uses adaptive power control to reduce active power consumption by the device. SmartReflex voltage control in the device is based on the dedicated SmartReflex modules and the voltage processors, in addition to the voltage controller and I²C interface, which are shared with the voltage FSMs and voltage control registers.

The SmartReflex modules allow a continuous real-time voltage supply and device performance monitoring to do the following:

- Minimize the supply voltage to reduce the device power consumption.
- Maintain the desired device performance (by dynamically adjusting the device voltage) as the temperature of the device varies.

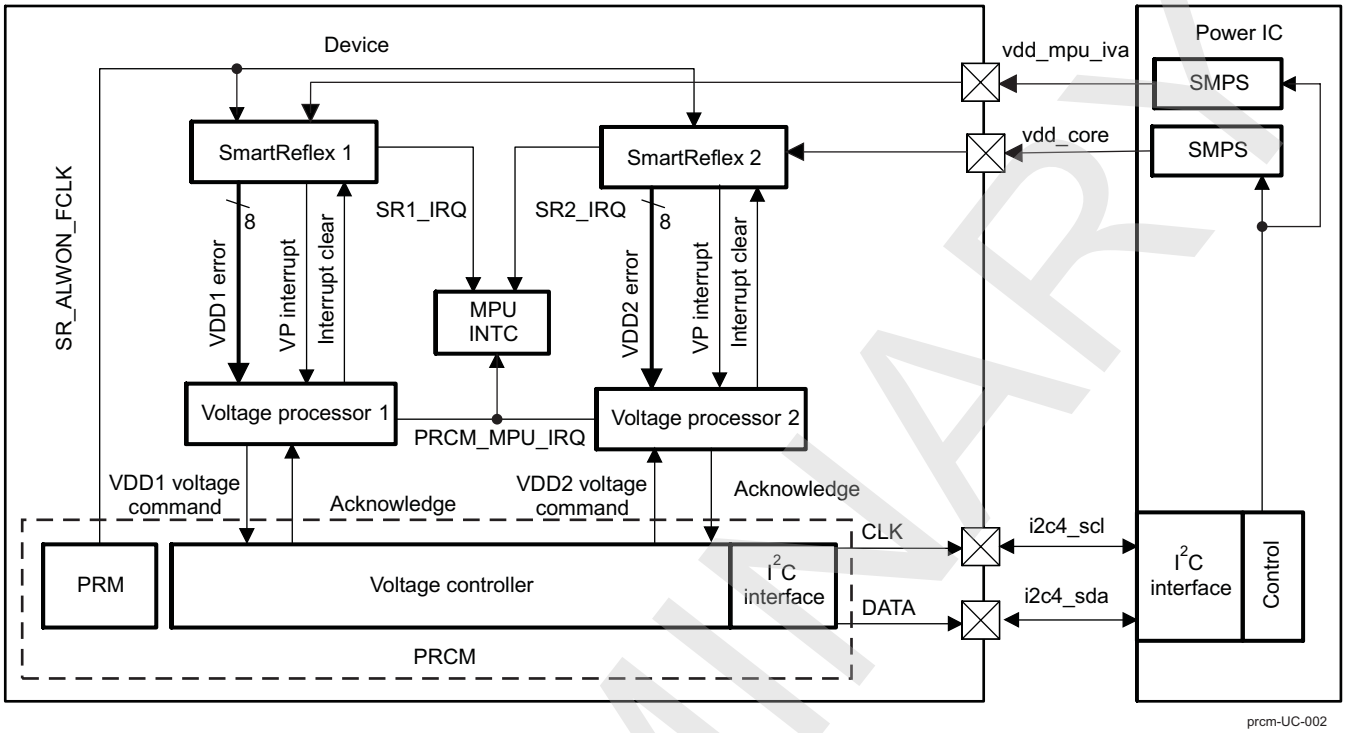
Within the device, the SmartReflex modules can be used to stabilize performance at a given OPP or for the DVFS (that is, switching from one OPP to another).

Because the SmartReflex modules and the voltage processors are dedicated to SmartReflex voltage control, they are described together in this section.

3.5.6.5.4.1 SmartReflex in the Device

Figure 3-82 shows the SmartReflex integration.

Figure 3-82. SmartReflex Integration

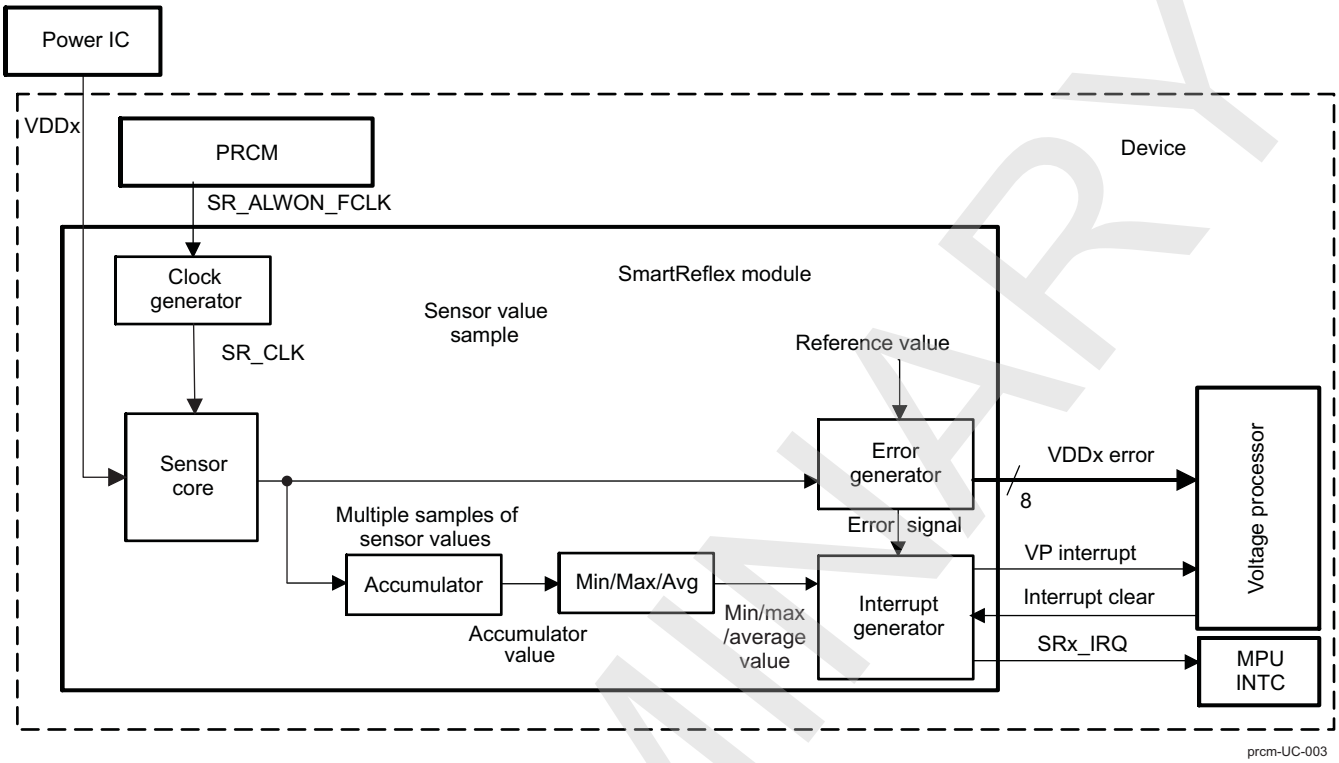


SmartReflex voltage control in the device is implemented for simultaneous control of two independent voltage sources. One SmartReflex module controls the VDD1 voltage, while the second one is dedicated to VDD2 control. Each SmartReflex module is connected to a voltage processor. Voltage commands from both voltage processors are passed to a voltage control, which sends them through a dedicated I^2C master interface to the power IC.

3.5.6.5.4.2 SmartReflex Module

Figure 3-83 is a functional overview of the SmartReflex module.

Figure 3-83. SmartReflex Module Functional Overview



3.5.6.5.4.3 SmartReflex Submodules

The SmartReflex module is enabled by setting the SRn[(1)] The SRnSRCONFIG[11] SR_EN bit is composed of six blocks:

- Clock generator
- Sensor core
- Accumulator
- Minimum/maximum/average
- Error generator
- Interrupt generator

Clock Generator

The clock generator provides the internal SR_CLK sampling clock to the sensor core of the module. The SRn.SRCONFIG[21:12] SRCLKLENGTH bit field allows the setting of the frequency divider ratio between the SR_ALWON_FCLK and the SR_CLK. It is calculated using Equation 1:

$$SRn.SRCONFIG[21:12]\ SRCLKLENGTH = f_{SR\_ALWON\_FCLK}/(2 * f_{SR\_CLK}) \quad (1)$$

Where $f_{SR\_ALWON\_FCLK}$ is the frequency of the SR_ALWON_FCLK and f_{SR_CLK} is the desired SR_CLK frequency.

To accurately use the target values programmed for SmartReflex modules in the device, the SRCLKLENGTH parameter must be set correctly. The target values for the SmartReflex modules are calculated with the SR_CLK frequency set at 100 kHz. It is thus mandatory that the value of the SRCLKLENGTH parameter is calculated from Equation 4-1 with f_{SR_CLK} set at 100 kHz.

For example, if the system clock has a frequency of 38.4 MHz, and the target SR_CLK frequency is 100 kHz, the SRn.SRCONFIG[21:12] SRCLKLENGTH is 192 (0x0C0).

Sensor Core

(1) SR1 and SR2 instances of the SmartReflex module in the device; n varies from 1 to 2.

The sensor core receives the SR_CLK sampling clock and the voltage to be sensed. It generates sensor value samples proportional to the voltage sensed. For accuracy, a sensor core is composed of two sensors and generates two values per sample (one from each sensor).

The two sample values generated by the sensor core output can be read from the SRn.SENVAL[15:0] SENNVAL bit field and the SRn.SENVAL[31:16] SENPVAL bit field.

The sensor core is enabled by the SRn.SRCONFIG[10] SENENABLE bit.

Accumulator

The accumulator consists of two stacks that store multiple samples of the two sensor values received from the sensor core.

The SRn.SRCONFIG[31:22] ACCUMDATA bit field defines the size of the accumulator in the number of samples to be stored. The allowable range is from 2 to 1023. The SRn.SRCONFIG[31:22] ACCUMDATA value is related to the desired sampling time window ($T_{TimeWindow}$) and the SR_CLK frequency (f_{SR_CLK}). It can be calculated using Equation 2:

$$\text{SRn.SRCONFIG[31:22] ACCUMDATA} = T_{TimeWindow} * f\ \text{SR\_CLK} \quad (2)$$

For example, for an accumulator time window of 10 ms and SR_CLK frequency of 32 kHz, the SRn.SRCONFIG[31:22] ACCUMDATA value is 320 (0x140). The accumulation window must be large enough so that the minimum, maximum, and average counter values are accurate.

Minimum/Maximum/Average

The minimum/maximum/average block reads the samples stored in the accumulator and returns the minimum, maximum, and average values of the samples. Because the accumulator contains two separate groups of samples (one from each sensor of the sensor core), the minimum/maximum/average block also generates two sets of minimum, maximum, and average values.

The minimum, maximum, and average values of the samples of the first sensor can be read from the SRn.SENMIN[15:0] SENNMIN, SRn.SENMAX[15:0] SENNMAX, and SRn.SENAVG[15:0] SENNAVG bit fields.

For the sample values of the second sensor, the minimum, maximum, and average values can be read from the SRn.SENMIN[31:16] SENPMIN, SRn.SENMAX[31:16] SENPMAX, and SRn.SENAVG[31:16] SENPAVG bit fields.

The minimum/maximum/average block is enabled by the SRn.SRCONFIG[8] MINMAXAVGENABLE bit.

Error Generator

The error-generator block reads the sample value generated by the sensor core and compares it with a reference value to calculate the error. This error is then passed to the voltage processor and the internal interrupt generator block.

The reference value for a given OPP of the device is configured by setting the SRn.NVALUERECIPROCAL[23:20] SENPGAIN, SRn.NVALUERECIPROCAL[19:16] SENNGAIN, SRn.NVALUERECIPROCAL[15:8] RNSENP, and SRn.NVALUERECIPROCAL[7:0] RNSENN bit fields by reading corresponding values from the eFuses (see Section 3.5.6.5.4.5, *eFuse Values*).

The error generator sets the SRn.SRSTATUS[1] ERRGEN_VALID status bit when a valid error value is set in the SRn.SENERROR_REG register.

The SRn.SENERROR_REG register contains the average error (SRn.SENERROR_REG[15:8] AVGERROR) and the error value (SRn.SENERROR_REG[7:0] SENERROR).

The error generator block is enabled by the SRn.SRCONFIG[9] ERRORGENERATORENABLE bit.

Interrupt Generator

The interrupt generator block generates interrupts to the MPU INTC and the voltage processor module (if the corresponding interrupts are enabled) to indicate errors.

Table 3-84 and Table 3-85 list the interrupt sources in the SmartReflex module and their enable and status bits.

Table 3-84. SmartReflex Interrupts

Interrupt Type	Destination	Description
Accumulator	MPU INTC	The minimum/maximum/average module has completed computation over the accumulator data.
Valid	MPU INTC	The average error is less than 2 percent of the true average error.
Disable acknowledge	MPU INTC	The SmartReflex module is disabled and has cleared all MCU and VP interrupts (internal registers are reset). This interrupt indicates to the software that the SmartReflex module is available for programming.
Bounds	MPU INTC	The frequency error has crossed the maximum limit (ERRMAXLIMIT) or the minimum limit (ERRMINLIMIT).
	Voltage processor	

The interrupt mappings to the MPU INTC are:

- SR1_IRQ from the SmartReflex1 module to the M_IRQ_18 interrupt line of the MPU INTC
- SR2_IRQ from the SmartReflex2 module to the M_IRQ_19 interrupt line of the MPU INTC

Table 3-85. SmartReflex Interrupt Enable and Status Bits

Interrupt Type	Enable Bit	Status Bit
Accumulator	SRn.IRQENABLE_SET[3] MCUACCUMINTENASET	SRn.IRQSTATUS[3] MCUACCUMINTSTATENA
Valid	SRn.IRQENABLE_SET[2] MCUVALIDINTENASET	SRn.IRQSTATUS[2] MCUVALIDINTSTATENA
Disable acknowledge	SRn.IRQENABLE_SET[0] MCUDISABLEACTINTENASET	SRn.IRQSTATUS[0] MCUDISABLEACKINTSTAT
Bounds	SRn.IRQENABLE_SET[1] MCUBOUNDSINTSTATENA	SRn.IRQSTATUS[1] MCUBOUNDSINTENASET
	SRn.ERRCONFIG[22] VPBOUNDSINTENABLE	SRn.ERRCONFIG[23] VPBOUNDSINTSTATENA

The minimum and maximum error limits for the bounds interrupt are configured in the SRn.ERRCONFIG[15:8] ERRMAXLIMIT and SRn.ERRCONFIG[7:0] ERRMINLIMIT bit fields.

With automatic (hardware) voltage control, the voltage processor interrupt (iSRn.ERRCONFIG[22] VPBOUNDSINTENABLE) is enabled and the SmartReflex module interrupts the voltage processor module when the error crosses the error limits. In this case, the MPU interrupts can also be enabled to allow the software to monitor the SmartReflex module behavior.

With manual (software) voltage control, the voltage processor interrupt remains disabled and only the MPU interrupts are enabled. Thus, when an interrupt condition occurs, the MPU is interrupted and the software can then control the voltage by generating voltage commands.

3.5.6.5.4.4 Status Register

The status register (SRSTATUS) indicates the validity of the minimum/maximum/average and error-generator output values.

SRSTATUS has the following bits and bit fields:

- SRn.SRSTATUS[3] AVGERRVALID: Indicates the validity of the value in the SRn.SENERROR_REG[15:8] AVGERROR bit field. When the value is 0, the average error is not valid. When the value is 1, the average error is within 2 percent of the valid average error.
- SRn.SRSTATUS[2] MINMAXAVGVALID: Indicates the validity of the SRn.SENVAL, SRn.SENMIN, SRn.SENMAX, and SRn.SENAVG registers. When the value is 0, the registers are not valid. When the value is 1, the registers contain valid values, although the values are not necessarily fully accumulated.
- SRn.SRSTATUS[1] ERRGEN_VALID: Indicates the validity of the value in the SRn.SENERROR_REG[7:0] SENERROR bit field. When the value is 0, the error value is invalid. When the value is 1, the error value is valid.
- SRn.SRSTATUS[0] MINMAXAVGACCUMVALID: Indicates that the SRn.SENVAL, SRn.SENMIN,

SRn.SENMAX, and SRn.SENAVG registers contain their final values accumulated over the defined sample time period.

3.5.6.5.4.5 SmartReflex Parameters Set After Silicon Characterization

Certain parameters of the SmartReflex module are characterized and calibrated after silicon testing. These values are then either set in the eFuse farm of the device or provided in a separately. The user must configure these parameters according to their given values to ensure correct functioning of the module.

The values for the following parameters (explained in Section 3.5.6.5.4.3) are set in the device eFuse after device silicon characterization:

- SRn.SRCONFIG[1] SENNENABLE
- SRn.SRCONFIG[4:3] SENPENABLE
- SRn.NVALUERECIPROCAL[23:20] SENPGAIN
- SRn.NVALUERECIPROCAL[19:16] SENNGAIN
- SRn.NVALUERECIPROCAL[15:8] RNSENP
- SRn.NVALUERECIPROCAL[7:0] RNSENN

The eFuse values of these parameters can be read from the corresponding registers of the SCM. The SCM registers associated with the parameters SENPGAIN, SENNGAIN, RNSENP, and RNSENN of the SR1 module are:

- CONTROL.CONTROL_FUSE_OPP50_VDD1
- CONTROL.CONTROL_FUSE_OPP100_VDD1
- CONTROL.CONTROL_FUSE_OPP130_VDD1
- CONTROL.CONTROL_FUSE_OPP1G_VDD1

The SCM registers associated with the parameters SENPGAIN, SENNGAIN, RNSENP, and RNSENN of the SR2 module are:

- CONTROL.CONTROL_FUSE_OPP50_VDD2
- CONTROL.CONTROL_FUSE_OPP100_VDD2

The SCM register associated with the parameters SENNENABLE and SENPENABLE of the SR1 and SR2 module is:

- CONTROL.CONTROL_FUSE_SR

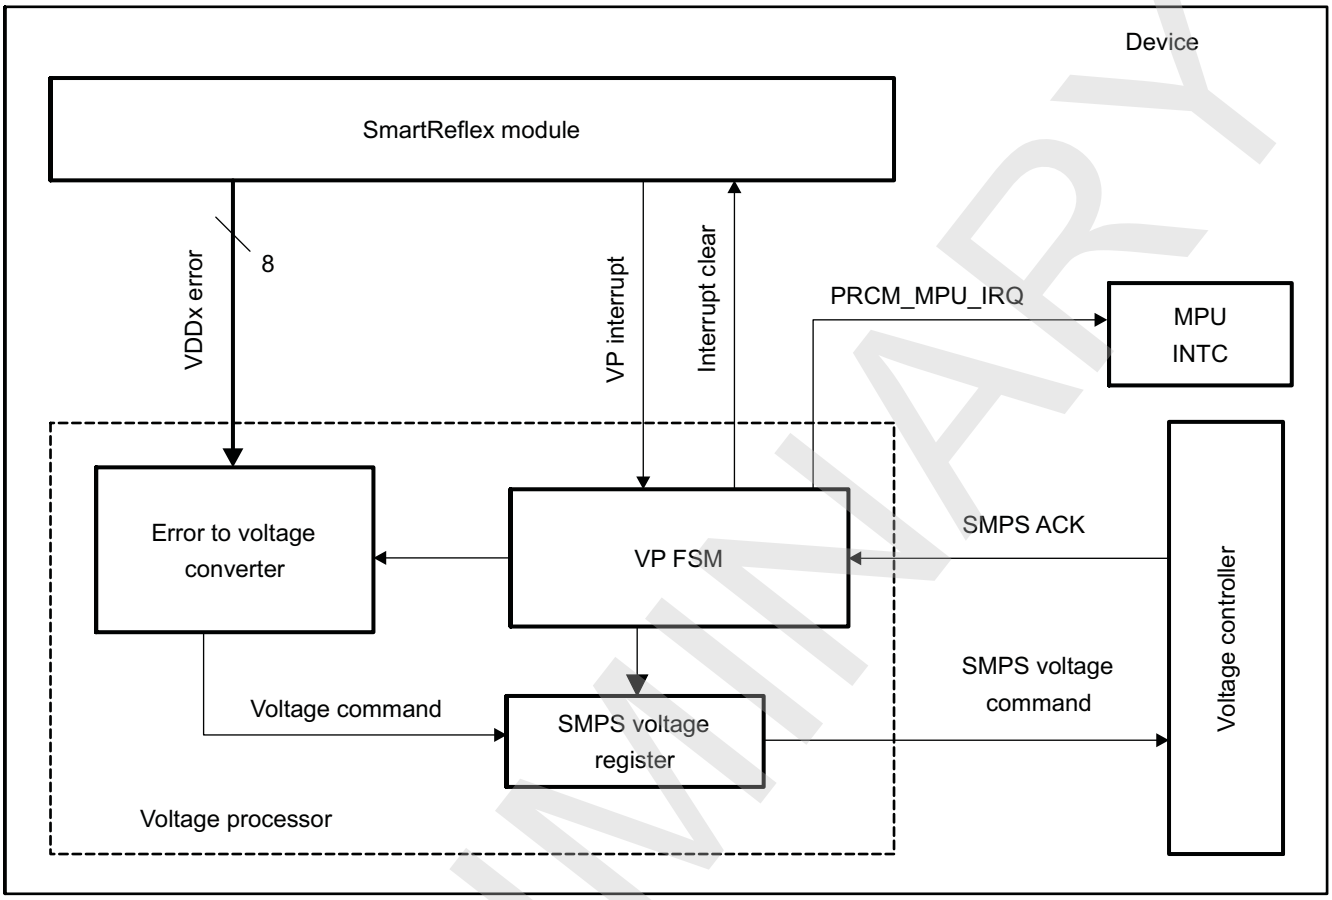
Information about the following parameters of the SmartReflex module is provided after silicon characterization :

- SRn.AVGWEIGHT[3:2] SENPAVGWEIGHT
- SRn.AVGWEIGHT[1:0] SENNAVGWEIGHT
- SRn.ERRCONFIG[18:16] ERRWEIGHT
- SRn.ERRCONFIG[15:8] ERRMAXLIMIT
- SRn.ERRCONFIG[7:0] ERRMINLIMIT

3.5.6.5.4.6 Voltage Processor Module

Figure 3-84 is a functional overview of the voltage processor.

Figure 3-84. Voltage Processor Functional Overview



The voltage processor receives an error value and a VP interrupt signal from the SmartReflex module. Each time a new error value is sent, the SmartReflex module triggers an interrupt to inform the voltage processor. The voltage processor consists of an error-to-voltage command converter and a state controller. It processes an error and sends a voltage command to the voltage controller. It receives an acknowledge signal from the voltage processor when the SMPS receives the command. The voltage processor in turn acknowledges the SmartReflex module by clearing its interrupt.

The voltage processor is enabled by the PRCM.PRM_VPn_CONFIG[0] VPENABLE bit.

Voltage-Processor Interrupts

The voltage processor uses the PRCM_MPU_IRQ (M_IRQ_11) interrupt line of the MPU INTC to interrupt the MPU. Table 3-86 and Table 3-87 list the interrupt sources in the voltage processor module and their enable and status bits.

Table 3-86. Voltage Processor Interrupts

Interrupt Type	Destination	Description
Transaction done	MPU INTC	Voltage processor transaction is complete.
Equal value	MPU INTC	Voltage requested in the new voltage command is the same as the current SMPS voltage.
No SMPS acknowledge	MPU INTC	SMPS has not responded in a defined time interval to the transmitted voltage command.
Maximum VDD	MPU INTC	New voltage requested in the voltage command is equal to or greater than maximum VDD.
Minimum VDD	MPU INTC	New voltage requested in the voltage command is equal to or less than minimum VDD.

Table 3-86. Voltage Processor Interrupts (continued)

Interrupt Type	Destination	Description
OPP change done	MPU INTC	The average error is within the desired limit.

Table 3-87. Voltage Processor Interrupt Enable and Status Bits

Interrupt Type	Enable Bit	Status Bit
Transaction done	PRCM.PRM_IRQENABLE_MPU[21] VP2_TRANXDONE_EN	PRCM.PRM_IRQSTATUS_MPU[21] VP2_TRANXDONE_ST
	PRCM.PRM_IRQENABLE_MPU[15] VP1_TRANXDONE_EN	PRCM.PRM_IRQSTATUS_MPU[15] VP1_TRANXDONE_ST
Equal value	PRCM.PRM_IRQENABLE_MPU[20] VP2_EQVALUE_EN	PRCM.PRM_IRQSTATUS_MPU[20] VP2_ EQVALUE_ST
	PRCM.PRM_IRQENABLE_MPU[14] VP1_EQVALUE_EN	PRCM.PRM_IRQSTATUS_MPU[14] VP1_EQVALUE_ST
No SMPS acknowledge	PRCM.PRM_IRQENABLE_MPU[19] VP2_NOSMPSACK_EN	PRCM.PRM_IRQSTATUS_MPU[19] VP2_NOSMPSACK_ST
	PRCM.PRM_IRQENABLE_MPU[13] VP1_NOSMPSACK_EN	PRCM.PRM_IRQSTATUS_MPU[13] VP1_NOSMPSACK_ST
Maximum VDD	PRCM.PRM_IRQENABLE_MPU[18] VP2_MAXVDD_EN	PRCM.PRM_IRQSTATUS_MPU[18] VP2_MAXVDD_ST
	PRCM.PRM_IRQENABLE_MPU[12] VP1_ MAXVDD_EN	PRCM.PRM_IRQSTATUS_MPU[12] VP1_MAXVDD_ST
Minimum VDD	PRCM.PRM_IRQENABLE_MPU[17] VP2_MINVDD_EN	PRCM.PRM_IRQSTATUS_MPU[17] VP2_MINVDD_ST
	PRCM.PRM_IRQENABLE_MPU[11] VP1_MINVDD_EN	PRCM.PRM_IRQSTATUS_MPU[11] VP1_MINVDD_ST
OPP change done	PRCM.PRM_IRQENABLE_MPU[16] VP2_OPPCHANGEDONE_EN	PRCM.PRM_IRQSTATUS_MPU[16] VP2_OPPCHANGEDONE_ST
	PRCM.PRM_IRQENABLE_MPU [10] VP1_OPPCHANGEDONE_EN	PRCM.PRM_IRQSTATUS_MPU[10] VP1_OPPCHANGEDONE_ST

Voltage-Processor Status

The status of the voltage processor is represented by the following:

PRCM.PRM_VPn_VOLTAGE[7:0] VPVOLTAGE	Current voltage for SMPS	Value of the current voltage level requested by the voltage processor
PRCM.PRM_VPn_STATUS[0] VPINIDLE	VP in inactive state	The voltage processor is in idle mode.

Voltage-Processor Parameters

The following parameters of the voltage processor must be configured:

Bit/Bit Field	Parameter	Description
PRCM.PRM_VPn_CONFIG[31:24] ERROROFFSET	Error offset	Error in voltage offset value
PRCM.PRM_VPn_CONFIG[231:16] ERRORGAIN	Error gain	Error in voltage gain value
PRCM.PRM_VPn_CONFIG[3] TIMEOUTEN	Time-out enable	Enables/disables the time-out set by the time-out delay parameter
PRCM.PRM_VPn_VSTEPMIN[7:0] VSTEPMIN	Minimum step size	Minimum voltage step size
PRCM.PRM_VPn_VSTEPMAX[7:0] VSTEPMAX	Maximum step size	Maximum voltage step size
PRCM.PRM_VPn_VLIMITTO[31:24] VDDMAX	Maximum VDD limit	Maximum voltage limit of the VDD
PRCM.PRM_VPn_VLIMITTO[23:16] VDDMIN	Minimum VDD limit	Minimum voltage limit of the VDD
PRCM.PRM_VPn_VLIMITTO[15:0] TIMEOUT	Time-out delay	Maximum delay between a voltage change command and its acknowledge
PRCM.PRM_VPn_CONFIG[15:8] INITVDD	Initial VDD voltage	Initial voltage set in the voltage processor
PRCM.PRM_VPn_CONFIG[2] INITVDD	Initialize VDD	Set initial voltage given in initial VDD voltage parameter in the voltage processor

Bit/Bit Field	Parameter	Description
PRCM.PRM_VPn_VSTEPMIN[23:8] SMPSWAITTIMEMIN	Minimum SMPS wait time	Slew rate for negative voltage steps
PRCM.PRM_VPn_VSTEPMAX[28:8] SMPSWAITTIMEMAX	Maximum SMPS wait time	Slew rate for positive voltage steps
PRCM.PRM_VPn_CONFIG[1] FORCEUPDATE	Force update	Sends the value of the VP current voltage parameter as the new voltage command to SMPS

3.5.6.5.4.7 SMPS Parameter Configuration

The values of the following parameters depend on the characteristics of the SMPS used:

- PRCM.PRM_VPn_CONFIG[31:24] ERROROFFSET
- PRCM.PRM_VPn_CONFIG[231:16] ERRORGAIN
- PRCM.PRM_VPn_VSTEPMIN[7:0] VSTEPMIN
- PRCM.PRM_VPn_VSTEPMAX[7:0] VSTEPMAX
- PRCM.PRM_VPn_VLIMITTO[31:24] VDDMAX
- PRCM.PRM_VPn_VLIMITTO[23:16] VDDMIN
- PRCM.PRM_VPn_VLIMITTO[15:0] TIMEOUT
- PRCM.PRM_VPn_VSTEPMIN[23:8] SMPSWAITTIMEMIN
- PRCM.PRM_VPn_VSTEPMAX[28:8] SMPSWAITTIMEMAX

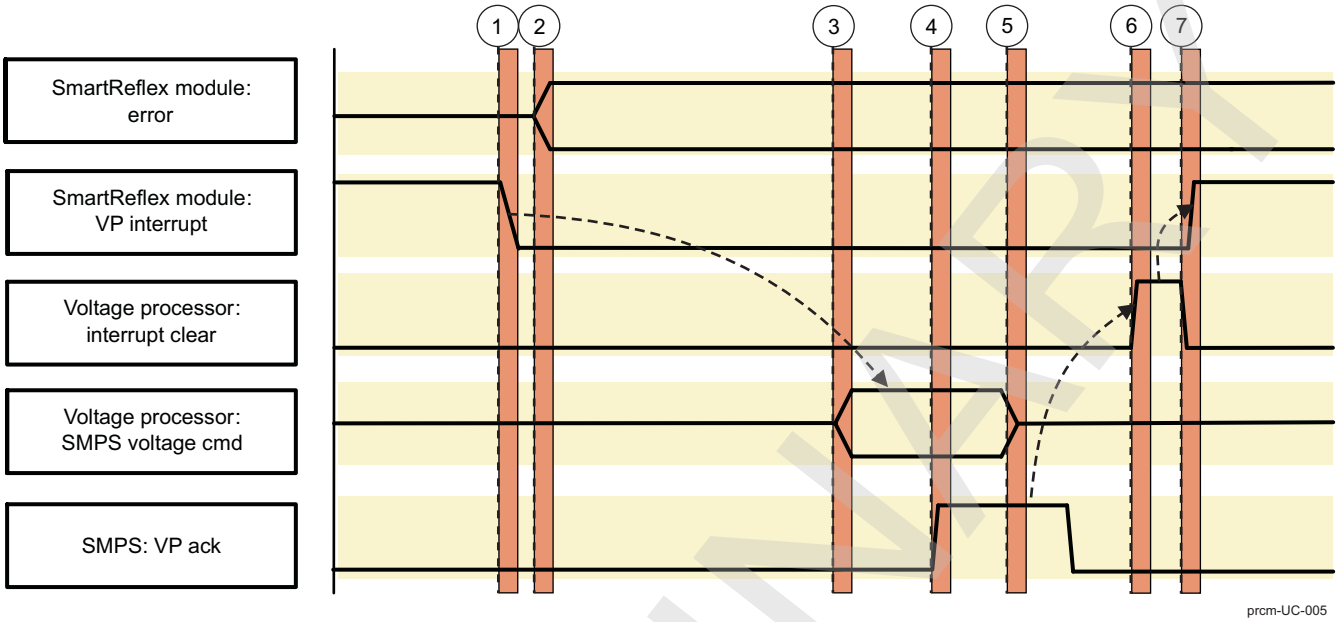
For information about the values of these parameters, see the specification document of the SMPS used.

3.5.6.5.4.8 Communication Between SmartReflex, Voltage Processor, Voltage Controller, and SMPS

The SmartReflex module, voltage processor, voltage controller, and SMPS implement a simple handshake protocol based on a request/acknowledge mechanism (see Figure 3-85):

1. The SmartReflex module generates a VP interrupt (clears to 0) when the average error crosses the minimum or maximum error bounds.
2. The VDDx error is passed to the voltage processor when automatic voltage control is enabled.
3. The voltage processor reads the error and generates the voltage command for the SMPS. It then informs the voltage controller that a new voltage command is ready for the SMPS. The voltage controller sends the voltage command to the SMPS (external power IC) through the dedicated I^2C interface.
4. The SMPS responds to the reception of the voltage command with an acknowledgement to the voltage controller, which in turn sends the acknowledgement to the voltage processor.
5. On reception of the voltage command by the SMPS, the voltage processor sends the interrupt-clear signal to the SmartReflex module. The SmartReflex module then clears the VP interrupt. The SmartReflex module is again ready to send a new frequency-error interrupt to the voltage processor.

Figure 3-85. SmartReflex - SMPS Communication for Automatic Voltage Adjustments



3.5.6.6 Analog Cells, LDOs, and Level Shifter Controls

In addition to the VDD1 and VDD2 voltage controls, the PRM handles the following operations automatically, based on hardware conditions, without any software control:

- Reduces SRAM LDOs voltage when all memories are in retention
- Reduces wake-up LDO voltage when the device enters off mode (wake-up leakage reduction)
- Increases wake-up LDO voltage when emulation trace is active
- Actively isolates level shifters during VDD1 and VDD2 removal
- Activates sleep mode in all analog cells when the device enters off mode

3.5.6.6.1 ABB LDOs Control

ABB LDO supports two voltage modes:

- BYPASS mode: In this mode the x_ABB LDO is bypassed and outputs the VDD_x_L voltages (x refers to MPU and IVA). This mode is activated when FBB is not required, or when voltage domain enters lowpower mode.
- FBB mode is enabled when the device is at highest OPP (OPP1G).

The PRCM provides the PRM_LDO_ABB_CTRL register for configuration with the following controls:

- SR2EN - To enable or bypass the ABB power management
- ACTIVE_FBB_SEL - To enable or bypass FBB mode
- SR2_WTCNT_VALUE - LDO settling delay on OPP change. The delay is in number of system clock cycles.

The PRCM provides PRM_LDO_ABB_SETUP register for control:

- OPP_SEL - Current operational OPP
- OPP_CHANGE - Initiate an OPP based ABB LDO setting change
- SR2_STATUS - Current mode of operation of ABB LDO
- SR2_IN_TRANSITION - ABB LDO is in transition.

3.5.6.6.2 SRAM Voltage Control

The two embedded SRAM LDOs supply regulated voltage (VDD4 or VDD5) to memory banks. The processor memory LDO (VDD4) has three reference voltages, while the CORE memory LDO (VDD5) supports two:

- 1.2 V is the normal voltage reference, used for processors OPP50 and OPP100.
- Tracking between 1.2 V and 1.35 V: The processor SRAM LDO (VDD4) tracks and follows VDD1 voltage when it exceeds OPP100 (1.2 V) nominal voltage. VDD1 (up to 1.35 V) is the overdrive voltage reference when processors operate at OPP1G.
- 1.05 V is set when all memory banks belonging to the LDO are in retention state.

When not used (all memories are off), the LDO is in sleep mode. These modes are managed automatically by hardware (PRM).

3.5.6.6.3 Wake-Up and Emulation Voltage Control

The embedded wake-up LDO (VDD3) supplies both WKUP and EMU power domains. It is permanently active and feeds the WKUP power domain continuously. An embedded switch allows the PRM to control power to the EMU power domain. This switch is closed on a software request command when a debug session starts, or automatically on JTAG plug detection.

This LDO has three reference voltages:

- 1.05 V is the normal voltage reference, used in device active mode.
- 1.15 V is the overdrive voltage reference used when emulation is activated and MPU emulation trace is required.
- 0.82 V is set when the device is in low-power (off) mode, to minimize leakage.

These modes are managed automatically by hardware.

3.5.7 PRCM Off-Mode Management

3.5.7.1 Overview

The CORE power domain can be switched from ON to OFF or retention state.

When the CORE power domain is inactive, the clock manager does not generate an interface clock, and device interconnects are inactive; therefore, the device is effectively in off mode. In retention state, however, the logic in the CORE domain is retained, and the device wake-up latency is small compared to the latency when the CORE power domain is in off state. In waking from the CORE domain off state, the CORE logic configuration must be loaded from a scratchpad memory in the WKUP power domain.

NOTE: Although some modules in the device can be kept active while the CORE power domain is off or in retention, this is not recommended.

When the device is put in off mode (the CORE power domain is in retention or off state), the device voltage domains can be switched off to minimize leakage currents. However, reactivity to wake-up events must be ensured.

The device supports a unique off-mode management scheme that allows deactivation of all modules, isolation of their outputs, and configuration of a dedicated off mode on the I/O pads of the device, to listen to wake-up events. A wake-up event on any I/O pad is detected by the PRM (in WKUP always-on power domain), which can then wake up the device.

3.5.7.2 Device Off-Mode Configuration

3.5.7.2.1 Overview

Any I/O pad of the device can be configured to generate a wake-up event when the device is in off mode. The off-mode scheme is based on the following components of the device:

- I/O pads
- SCM

Figure 3-86 is an overview of the I/O pad off-mode scheme. In this mode, the I/O pads of the device form a daisy chain. The I/O pad logic at the two ends of the chain is connected to the PRM.

When a wake-up event (WUEVT) occurs on an enabled I/O pad in the chain, the event is propagated through the chain to the PRM. Multiple I/O pads can receive a wake-up event simultaneously; however, the PRM receives only the OR output for all the enabled I/O pads. When the device wakes up, the MPU can determine all sources of the current wake-up event logged into the corresponding CONTROL.CONTROL_PADCONF_<IOpad>[15] WAKEUPEVENT0 or CONTROL.CONTROL_PADCONF_<IOpad>[31] WAKEUPEVENT1 bit in the SCM.

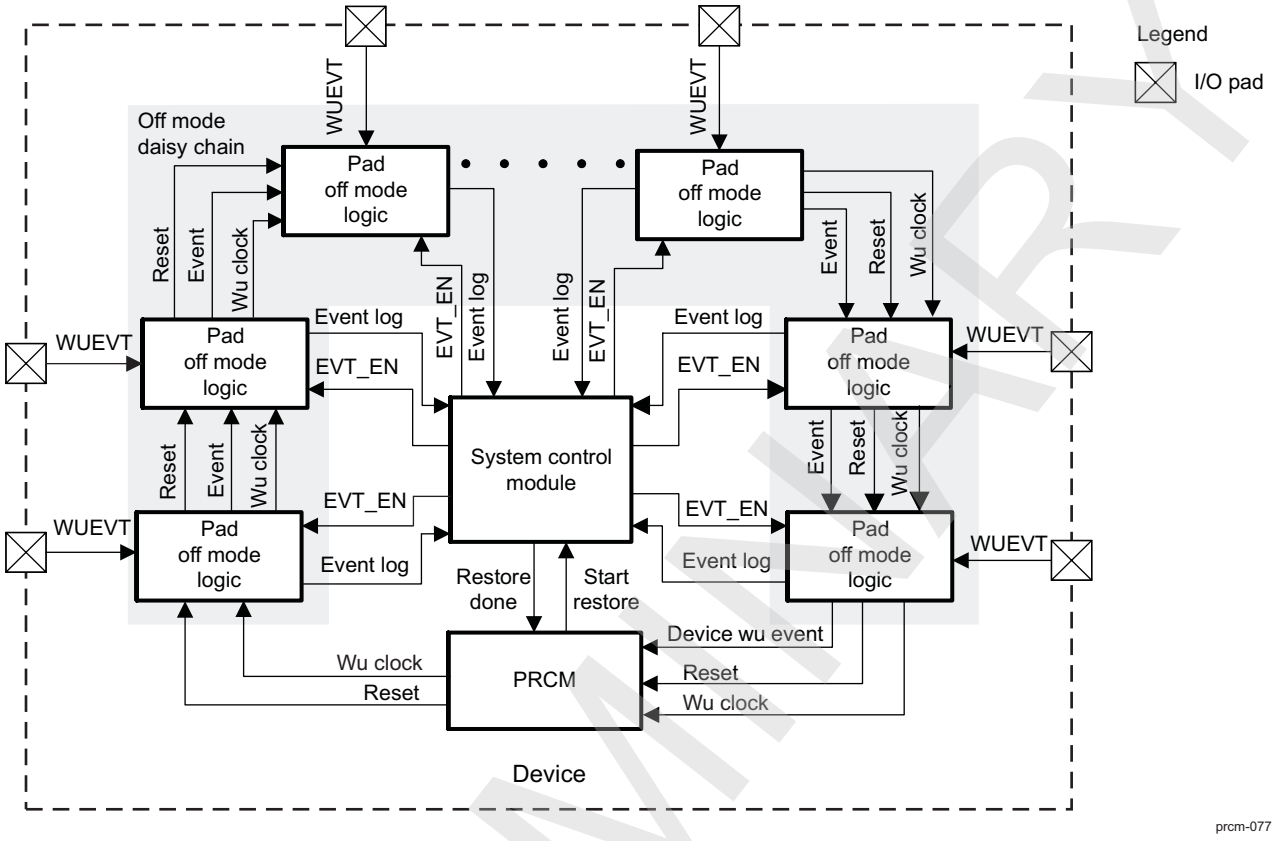
The I/O pad wake-up scheme must be enabled globally by setting the PRCM.PM_WKEN_WKUP[8] EN_IO bit and the PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN bit. The wake-up event from each I/O pad of the device can be individually enabled/disabled (EVT_EN signal) by writing to the CONTROL.CONTROL_PADCONF_<IOpad>[14] WAKEUPENABLE0 or CONTROL.CONTROL_PADCONF_<IOpad>[30] WAKEUPENABLE1 bit in the SCM.

For information about the SCM, see Chapter 13, *System Control Module*.

NOTE: As explained previously (see Section 3.5.4, *Idle and Wake-Up Management*), module-specific wake-up events other than the I/O pad wake-up scheme can wake up the device from off mode. For example, the GPIO pads in the WKUP power domain can also wake up the device.

NOTE: For the wake-up features of the GPIO pads , see Chapter 25, *General-Purpose Interface*.

Figure 3-86. Device Off-Mode Control Overview



3.5.7.2.2 I/O Wake-Up Mechanism

There are two ways to capture an I/O event. The expected way is to use GPIO modules. However, these modules may be powered-off when there is a need to capture an I/O event. The second way to capture an I/O event is through an I/O wake-up scheme controlled by the I/O daisy chain.

Only one GPIO module is in the WKUP domain, which is not switchable, and the other GPIO modules are in the PER domain, which is switchable. Therefore, the I/O wake-up scheme for the corresponding I/O must be enabled before transitioning the PER domain to a nonfunctional state. This typically happens when the device is programmed to enter OFF state.

During off mode, only six pins of the GPIO module in the WAKEUP domain are wake-up capable; therefore, the I/O wake-up scheme must be enabled for the other 26 I/Os before transitioning to OFF state.

The I/O wake-up scheme can be enabled when the PER domain is in ACTIVE state.

Software must enable and disable the I/O wake-up scheme and ensure an overlap window between the GPIO wake-up capability and the I/O wake-up capability. Software must manage this overlap window.

The I/O wake-up scheme in each pad is enabled through the I/O daisy chain:

- The I/O wake-up capability is enabled by programming the corresponding register (CONTROL.CONTROL_PADCONF_X) in the control module.
- The global I/O wake-up enable bit is enabled by programming a dedicated register (PRCM.PM_WKEN_WKUP[8] EN_IO) in the PRCM module.
- The I/O wake-up scheme is enabled by triggering the I/O daisy chain control (Wu clock) by programming a dedicated register (PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN) in the PRCM module.

Software must wait for the I/O daisy chain to complete before it transitions the PER domain to a nonfunctional state. This is done by polling a dedicated status bit in the PRCM module (PRCM.PM_WKST_WKUP[16] ST_IO_CHAIN). This status bit must be cleared by software when the bit is read to 1.

The I/O wake-up scheme in each pad is disabled through the I/O daisy chain:

- The I/O wake-up scheme is disabled by programming the dedicated register (PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN) in the PRCM module.
- The global I/O wake-up enable bit is disabled by programming a dedicated register (PRCM.PM_WKEN_WKUP[8] EN_IO) in the PRCM module.
- The I/O wake-up scheme is disabled by triggering the I/O daisy chain control (Wu clock) by writing 1 in a dedicated register (PRCM.PM_WKST_WKUP[8] ST_IO) in the PRCM

  This bit is also used to log the source of the I/O wakeup. Writing 1 in this register clears this bit to 0.

3.5.7.3 CORE Power Domain Off-Mode Sequences

The I/O pad wake-up scheme can be activated to detect wake-up events when the CORE power domain is switched to inactive, retention, or off state. The off state sequences for the CORE power domain include the sequence for going from on state to retention or off power state (while enabling the I/O pad wake-up scheme), and then switching back to the on power state (while disabling the I/O pad wake-up scheme) on an I/O wake-up event.

3.5.7.3.1 Sleep Sequences (Transition From On to Retention/Off)

When the CORE power domain is in retention state, the logic is switched off, its context is saved by the RFFs in the modules, and the memory blocks are retained. In off state, however, the logic and memories are switched off, and the RFFs are not saved.

NOTE: If the PER power domain is kept on while the CORE power domain is in retention state, all I/O wake-up enable (EVT_EN signals) signals to the I/O pads related to the PER power domain inputs must be disabled (by clearing the CONTROL.CONTROL_PADCONF_<IOpad>[14] WAKEUPENABLE bit in the SCM). in this case, wake-up events are generated by the PER domain and not through the daisy chain.

For information about the SCM, see Chapter 13, *System Control Module*.

The following sequence is used to go from on to retention or off state:

1. The software sets the PRCM.PM_WKEN_WKUP[8] EN_IO bit and the PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN bit to enable the I/O pad wake-up scheme.
2. The MPU initiates the sleep sequence. When all conditions are met, the CORE power domain clocks are shut down. At this stage, most of the pads are inactive, but some, such as the PER and DSS power domains, can stay active.
3. The PRM initializes and resets the I/O wake-up detection scheme and saves all RFFs. Its CORE power domain output is isolated from the I/O pads.
4. The PRM switches the CORE power domain to retention/off power state. The I/O configuration is saved on wake-up power domain registers; see Section 13.4.4.4.1, *Save-and-Restore Mechanism*, in Chapter 13, *System Control Module*, for more information.
5. The PRM waits for a wake-up event from the daisy chain. Other possible wake-up sources can be a wake-up event from a module in the wake-up power domain or from a global warm reset.

NOTE: When the CORE power domain is in retention state, VDD2 voltage must be at retention or on voltage level to maintain stable CORE power domain output values to the I/Os.

3.5.7.3.2 Wake-Up Sequences (Transition From Retention/Off to On)

The PRM detects a wake-up event from the daisy chain. Several wake-up events can occur simultaneously, but PRM only sees the ORing of them. Depending on whether the CORE power domain is in retention or off state, the following sequence is followed to wake up the CORE and MPU power domains:

1. When the CORE power domain wakes up from off/retention power state, reset is asserted for both the MPU and the CORE power domains.
2. The MPU and the CORE power domains are switched to ON power state.
3. The domain clocks of the MPU and the CORE power domains are restarted.
4. If the CORE power domain was in the off power state, its reset is released before the MPU power domain.
   - The hardware restores the I/O pad configuration and some configuration registers of the control module. This configuration has been saved in the scratchpad memory (by the control module save procedure initiated by software control prior to the transition to off power state).
   - The PRCM module switches the I/O pad configurations to the normal restored configuration (The I/O pad isolation is released).
   - The reset is released for MPU power domain.
5. If the CORE power domain was in the retention power state, the reset is released for both the MPU and the CORE power domains at the same time.
6. When the MPU boots, the software accesses the SCM to read the wake-up event source (identified by the CONTROL.CONTROL_PADCONF_< IOpad>[15] WAKEUPEVENT bits in the SCM corresponding to all enabled pads).
7. The software disables the wake-up daisy chain by clearing the PRCM.PM_WKEN_WKUP[8] EN_IO bit and the PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN bit.

NOTE: A daisy-chain wake-up event always causes the MPU to restart and boot. Other independent wake-up events activated in off mode (for example, a GPIO wake-up event) always cause the CORE power domain to be activated. The MPU is wakened if a wake-up dependency has been set by the user, or if the modem generates an interrupt to the MPU.

3.5.7.4 Device Off-Mode Sequences

Device off-mode sequencing requires preliminary settings that can be done during device initialization. The following actions are performed once and remain valid for all device off/on transitions:

1. Configure valid off and active pad configuration for each pad by programming the SCM CONTROL.CONTROL_PADCONF_< IOpad> register.
2. Save the active pad configuration by asserting the CONTROL.CONTROL_PADCONF_OFF[1] STARTSAVE bit in the SCM. This process can be repeated each time the active pad configuration of the device is changed.
3. Set the SCM to smart-idle mode by configuring the CONTROL. CONTROL_SYSCONFIG[4:3] IDLEMODE bit field. This ensures that the module clocks remain active during the configuration save procedure.
4. Disable all the modules running on system clock or switch them on the 32 kHz clock when required.
5. Configure the voltage regulator setup times (the PRCM.PRM_VOLTSETUP1[15:0] SETUP_TIME1 and PRCM.PRM_VOLTSETUP1[31:16] SETUP_TIME2 bit fields).
6. Set sys_off_mode deassertion time in the PRCM.PRM_VOLTOFFSET[15:0] OFFSET_TIME bit field.
7. Configure the system clock oscillator setup time in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

For information about the SCM, see Chapter 13, *System Control Module*.

3.5.7.4.1 Sleep Sequences

The sleep sequences exemplify the two types of device transitions from ON to OFF mode:

- Device off-mode transition without using the SYS_OFF_MODE signal

- Device off-mode transition using only the SYS_OFF_MODE signal

3.5.7.4.1.1 Device Off-Mode Transition Without Using the SYS_OFF_MODE Signal

Each time the device enters I/O-pad-off configuration mode, the following sequence must be performed:

1. Software sets the PRCM.PM_WKEN_WKUP[8] EN_IO bit and the PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN bit to enable the I/O wake-up scheme.
2. The MPU initiates the sleep sequence. When all sleep conditions are met, all domain clocks are shut down. At this stage, all output pads are inactive and static.
3. The PRM configures the I/O daisy-chain for the wake-up detection scheme.
4. The CORE domain output is isolated.

   When conditions for entering off mode are met, the PRM proceeds with the sequence.
5. It switches off all domains, including the CORE power domain, and then switches from active mode pad configuratiON to OFF mode pad configuration.
6. It isolates the pads before the removal of VDD1 and VDD2.
7. It shuts down all analog cells (DPLL, DLL).
8. It switches to off all the DPLL power domains and the SR power domain.
9. It sends the off command for VDD1 to the voltage controller
10. It shuts down the SRAM LDOs.
11. The daisy chain is now ready to detect I/O pad wake-up events.
12. The PRM sends the off command for VDD1 to the voltage controller. Through I2C4, the voltage controller requests the power IC to set VDD1 to the voltage corresponding to the PRM_VC_CMD_VAL_0[7:0] OFF bit field. (A legacy mode exists where vmode pins can be used instead of I2C4, depending on the PRM_VOLTCTRL[4] SEL_VMODE bit. In this case, the PRM asserts sys_nvmode1 and the power IC updates VDD1 to its previously programmed value.)
13. Upon reception of the I2C4 transaction acknowledge, and after waiting for the VDD1 regulator setup time counter to expire (the PRM_VOLTSETUP1[15:0] SETUPTIME1 bit field), the PRM sends the off command for VDD2 to the voltage controller. Through I2C4, the voltage controller requests the power IC to set VDD2 to the voltage corresponding to PRM_VC_CMD_VAL_1[7:0] OFF bit field. (If vmode legacy mode is used, the PRM asserts sys_nvmode2 and the power IC restores VDD2 to its previously programmed value.)
14. Upon reception of the I2C4 transaction acknowledge, and after waiting for the VDD2 regulator setup time counter to expire (the PRM_VOLTSETUP1[31:16] SETUPTIME2 bit field), the PRM gates the internal system clock.
15. It releases sys_clkreq and disables the system clock oscillator (if used).
16. The PRM ramps down the wake-up LDO to 1 V.
17. It waits for a wake-up event from the daisy chain or from an internal event (timer) from the WKUP domain.

NOTE: If an I/O pad toggles, when the I/O daisy-chain is already configured for the wake-up detection scheme, and before off mode transition occurs, then a not real wake-up event is logged in its padconf register.

NOTE: The condition to release the PAD_OFF_MODE signal upon wakeup from off mode is selected through the PRM_VOLTCTRL[8] PAD_OFF_MODE_OVR bit. This signal can be released by software after the software is restored by an interface such as GPIO.

3.5.7.4.1.2 Device Off-Mode Transition Using Only the SYS_OFF_MODE Signal

Depending on the external power IC capability and the user setting, VDD1 and VDD2 voltage control may use the direct sys_off_mode signal and not send the commands through the I^2C interface.

in this case, the initial sequence for device off-mode transition is the same as in Section 3.5.7.4.1.1, *Device Off-Mode Transition Without Using SYS_OFF_MODE Signal*, up to Step 8. After this, the following steps are executed:

1. It shuts down the SRAM LDOs.
2. It asserts sys_off_mode. At this point, VDD1 and VDD2 are shut down.
3. It ramps down the wake-up LDO to 1 V.
4. It releases CLKREQ and disables the system clock oscillator (if used)
5. It waits for a wake-up event from the daisy chain.

3.5.7.4.2 Wake-Up Sequences

NOTE: vdda_dpll_per and vdda_dpll_dll can be ramped up any time before VDD1 ramps up.

3.5.7.4.2.1 Device Wakeup from Off Mode Without Using the SYS_OFF_MODE Signal

On detection of a wake-up event from the daisy chain, the PRM performs the following steps:

1. It enables the system clock oscillator, asserts sys_clkreq, and ramps up the wake-up LDO.
2. It waits for the oscillator set-up time and the wake-up LDO stabilization time.
3. It sends the on command for VDD2 to the voltage controller. Through I2C4, the voltage controller requests the power IC to set VDD2 to set the voltage corresponding to the PRM_VC_CMD_VAL_1[31:24] ON bit field. (A legacy mode exists where vmode pins can be used instead of I2C4, depending on the PRM_VOLTCTRL[4] SEL_VMODE bit. In this case, the voltage controller deasserts sys_nvmode2 and the power IC restores VDD2 to its previously programmed value). At this point, VDD2 ramps up (the reset is not yet asserted on VDD2 logic).
4. It waits for the VDD2 regulator setup time counter to expire (PRM_VOLTSETUP1[31:16] SETUPTIME2).
5. It sends the on command for VDD1 to the voltage controller. Through I2C4, the voltage controller requests the power IC to set VDD1 to set the voltage corresponding to the PRM_VC_CMD_VAL_0[31:24] ON bit field. (If vmode legacy mode is used, the voltage controller deasserts sys_nvmode1 and the power IC restores VDD1 to its previously programmed value). At this point, VDD1 ramps up (the reset is not yet asserted on VDD1 logic).
6. It waits for the VDD1 regulator setup time counter to expire (PRM_VOLTSETUP1[15:0] SETUPTIME1).
7. It restarts the memory LDOs.
8. It powers up all analog cells on the VDD2 domain and waits for the settling time of the LDO and analog cells (internal counter).
9. The following steps can occur in parallel:
   - The DPLL, CORE, and MPU power domains are powered up.
   - The reset on the eFuse controller, DPLL, CORE, SR, and MPU power domains is asserted.
10. When the CORE, MPU, DPLLs, and SR are on, the PRM releases the eFuse controller reset, and the eFuse scan starts.
11. When the scan completes, the DPLL resets are released. The DPLLs are in bypass and the clocks start flowing (DPLL1 and DPLL3).
12. When the CORE and MPU domains are on, the PRM releases their corresponding domain output isolations.
13. When the CORE power domain is on and DPLL3 is in bypass, the reset timer for the CORE power domain starts.
14. When the MPU power domain is on and DPLL1 is in bypass, the reset timer for the MPU power domain starts.
15. When the CORE reset time expires, the CORE domain reset is released.
16. When the CORE domain exits reset and the SCM context and I/O configuration are restored from ScratchPad, memory starts.
17. When the PRM receives the acknowledge from the SCM, it releases the MPU and CORE domain output isolations and the I/O isolation.

18. The PRM switches the I/O pad configuration only if the PRM_VOLTCTRL[8] PAD_OFF_MODE_OVR bit is set to 1; otherwise, the PAD configuration remains in off configuration until the software is restored and clears this bit.
19. When the MPU reset time expires and pad configuration returns to normal mode, the MPU domain reset is released.
20. When the MPU boots, the software accesses the control module to read the wake-up event source.
21. The software disables the I/O wake-up daisy chain by clearing the PRCM.PM_WKEN_WKUP[8] EN_IO bit and the PRCM.PM_WKEN_WKUP[16] EN_IO_CHAIN bit.

3.5.7.4.2.2 Device Wakeup From Off Mode Using Only the SYS_OFF_MODE Signal

Depending on the external power IC capability and the user setting, VDD1 and VDD2 voltage control use the direct sys_off_mode signal and do not send commands through the I^2C interface.

in this case, the first part of the sequence in Section 3.5.7.4.2.1 is as follows.

Upon detection of a wakeup from the daisy chain, the PRM performs the following steps:

1. It enables the system clock oscillator and asserts sys_clkreq.
2. It ramps up the wake-up LDO.
3. It releases sys_off_mode.
4. It waits for the system clock oscillator setup time.
5. It waits for VDD1 and VDD2 setup time. The two counts are started in parallel.
6. When both timers expire, the following steps happen in parallel:
   - Reset is asserted on the MPU and CORE power domains.
   - The MPU and CORE power domains are powered up.
   - The PRM restarts the CORE and processor memory LDOs.
   - The PRM powers up all analog cells in the VDD1 and VDD2 domains.

3.6 PRCM Basic Programming Model

The PRCM module supports an extensive set of module-specific registers that allow programming control over numerous features of the clocks, resets, and power-management signals for each power domain of the device.

These registers are fully programmable and accessible by the MPU and the IVA2.2 subsystems.

Logically, the registers are grouped into five categories:

- Global
- Clock management
- Reset management
- Power management
- Voltage management

3.6.1 Global Registers

3.6.1.1 Revision Information Registers

- CM_REVISION: Indicates the CM module revision code; it is read-only
- PRM_REVISION: Indicates the PRM module revision code; it is read-only

3.6.1.2 PRCM Configuration Registers

- CM_SYSCONFIG: Holds an AUTOIDLE bit to control the CM internal clock autogating feature
- PRM_SYSCONFIG: Holds an AUTOIDLE bit to control the PRM internal clock autogating feature

3.6.1.3 Interrupt Configuration Registers

The PRM can interrupt the MPU and the IVA2.2 subsystems as a result of four events:

- PRM internal event (event generator, sleep transition, wake-up transition, voltage processors, voltage controller)
- Peripheral wake-up event for a peripheral with interrupt capability (GPTIMER[1..11], GPIO[1..6], McBSP[1..5], UART[1..4], HS USB OTG, I2C[1..3], McSPI[1..4], MMC[1,2], SR[1,2])
- Module/device-level event not associated with any interrupt (DPLL recalibration, I/O wakeup)

The PRM interrupt is enabled by programming the PRM_IRQENABLE_<processor_name> register; the interrupt status can be read from the PRM_IRQSTATUS_<processor_name> register.

The device has four processor interrupt registers:

- PRM_IRQSTATUS_MPU
- PRM_IRQENABLE_MPU
- PRM_IRQSTATUS_IVA2
- PRM_IRQENABLE_IVA2

3.6.1.3.1 MPU Interrupt Event Sources

The MPU interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the MPU interrupt controller.

Multiple events can activate this interrupt line:

- MPU peripheral group wake-up event
- Event-generator module end-of-on time and end-of-off time events
- Sleep or wake-up transition (SGX, USBHOST, IVA2, PER, DSS, CAM, NEON, EMU power domains)
- DPLL1/DPLL2/DPLL3/DPLL4/DPLL5 recalibration request
- I/O pad wake-up event
- Voltage processor 1 or 2 OPP Change Done event
- Voltage processor 1 or 2 new voltage reached the minimum voltage value allowed.
- Voltage processor 1 or 2 new voltage reached the maximum voltage value allowed.
- Voltage processor 1 or 2 time-out occurred while waiting for the power IC device acknowledge.
- Voltage processor 1 or 2 new voltage is the same as the current one.
- Voltage processor 1 or 2 transaction is done.
- Slave address in an I^2C frame sent by the voltage controller not acknowledged by the power IC device
- Register address in an I^2C frame sent by the voltage controller not acknowledged by the power IC device
- Last byte of an I^2C frame issued from the bypass port or the voltage manager FSM ports sent by the voltage controller not acknowledged by the power IC device

The end-of-on time period and end-of-off time period events of the event generator module are sources of interrupts to the MPU processor (the corresponding bits in the PRM_IRQENABLE_MPU are set to 1). The end-of-off time period is the source of wake-up events on the MPU domain.

The MPU can force a sleep or wake-up transition on some domains (SGX, USBHOST, IVA2, PER, DSS, CAM, NEON, EMU). The PRM triggers the MPU interrupt when the domain enters a power state. The software must clear the CM_CLKSTCTRL_<domain_name> register only after getting the interrupt. If the software clears this bit before getting the interrupt, the interrupt never occurs, regardless of whether the transition occurs.

An interrupt for a peripheral with wake-up capability is enabled when the wake-up enable bit (PM_WKEN_<domain_name> register type) and group select bit (PM_<processor_name>GRPSEL_<domain_name> type of register) are set to 1.

The PRM triggers its interrupt line on the I/O daisy chain wake-up event. This wake-up event is enabled by setting the corresponding bit in the PRCM.PM_WKEN_WKUP register to 1.

The PRM triggers the MPU interrupt as long as the DPLL recalibration flag is set and the corresponding interrupt enable bit in the PRM_IRQENABLE_<processor_name> register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

3.6.1.3.2 MPU Interrupt Registers

3.6.1.3.2.1 PRM_IRQENABLE_MPU (MPU Interrupt Enable Register)

The MPU interrupt enable register allows independent masking/unmasking of each MPU internal interrupt source.

NOTE: If the following interrupts are enabled and the MPU power domain is idled, then when the event occurs, the PRCM module sets the interrupt that wakes up the power domain:

- DPLL1/DPLL2/DPLL3/DPLL4/DPLL5 recalibration event
- Voltage controller errors

3.6.1.3.2.2 PRM_IRQSTATUS_MPU (MPU Interrupt Status Register)

The MPU interrupt status register provides the status of all PRCM internal events that can generate an MPU interrupt. Software must read this register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

3.6.1.3.3 IVA2.2 Interrupt Event Sources

The IVA2.2 interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the IVA2.2 interrupt controller.

Three events can activate this interrupt line:

- An IVA2.2 peripheral group wake-up event
- A force wake-up transition completion (IVA2 domain)
- A required IVA2 DPLL recalibration

The PRM also interrupts IVA2.2 if the corresponding bit in the PM_IVA2GRPSEL_WKUP register is set to 1.

The PRM triggers the interrupt line dedicated to the IVA2 processor when the MPU performs a force wake-up transition on the IVA2 domain. This interrupt is triggered under the same conditions as that of the MPU.

The PRM triggers an IVA2.2 interrupt if the DPLL recalibration flag is set and the corresponding interrupt enable bit in the PRM_IRQENABLE_<processor_name> register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

3.6.1.3.4 IVA2 Interrupt Registers

3.6.1.3.4.1 PRM_IRQENABLE_IVA2 (IVA2.2 Interrupt Enable Register)

The IVA2.2 interrupt enable register allows independent masking/unmasking of each of the three internal interrupt sources.

NOTE: If the IVA2 DPLL recalibration event interrupt is enabled and the IVA2 power domain is idled, then when the event occurs, the PRCM module sets the interrupt, thus waking up the power domain.

3.6.1.3.4.2 PRM_IRQSTATUS_IVA2 (IVA2.2 Interrupt Status Register)

The IVA2.2 interrupt status register provides the status of the three events that can generate an IVA2.2 interrupt. Software must read the register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

3.6.1.4 Event Generator Control Registers

For details about the event generator module, see the public *ARM Cortex-A8* technical reference manual.

In the PRCM module, three event generator registers allow configuration of the event generator module:

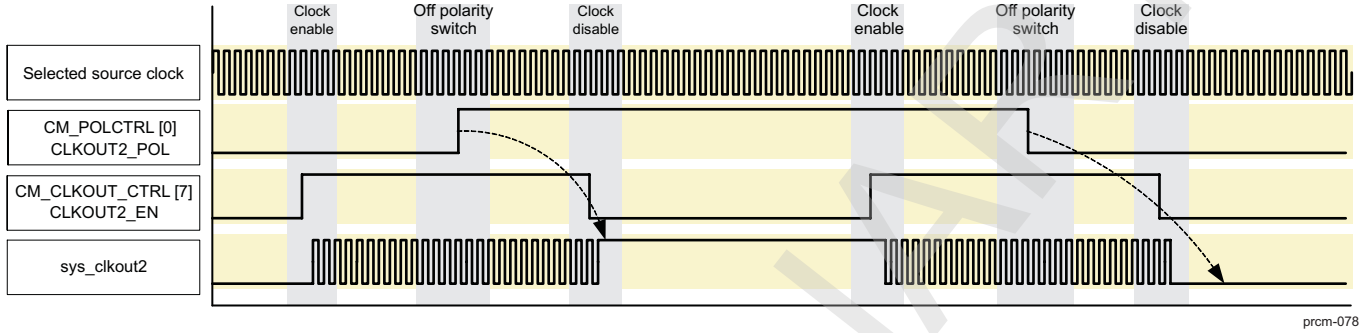
- PM_EVGENCTRL_MPU (event generator control register): Event-generator settings
- PM_EVGENONTIM_MPU (event generator on-time register): On-time duration setting
- PM_EVGENOFFTIM_MPU (event generator off-time register): Off-time duration setting

3.6.1.5 Output Signal Polarity Control Registers

3.6.1.5.1 CM_POLCTRL (CM Polarity Control Register)

The CM_POLCTRL register allows the setting of the polarity of sys_clkout2 when gated (disabled). sys_clkout2 can be gated to a low level or a high level, depending on the software programming of this register. Figure 3-87 shows the normal behavior of sys_clkout2 when gated.

Figure 3-87. sys_clkout2 Gating Polarity Control



3.6.1.5.2 PRM_POLCTRL (PRM Polarity Control Register)

The PRM polarity control register allows the setting of the polarity of the external signals controlled by the PRM. It contains the following polarity control bits:

- OFFMODE_POL: Polarity of sys_off_mode
- CLKOUT_POL: Polarity of sys_clkout1
- CLKREQ_POL: Polarity of sys_clkreq
- EXTVOL_POL: Polarity of both sys_nvmode signals: sys_nvmode1 and sys_nvmode2

At device power up, the reset values of polarity settings are OFFMODE_POL = 1 and CLKREQ_POL = 1. For details about using these signals, see Section 3.5.3, *Clock Manager Functional Description*.

3.6.1.6 SRAM Precharge Time Control Register

3.6.1.6.1 PRM_SRAM_PCHARGE (Voltage SRAM Precharge Counter Register)

The voltage SRAM precharge counter register allows the setting of the precharge duration of the SRAM. It has following bit field:

- PCHARGE_TIME: Number of system clock cycles defined for the SRAM precharge duration

3.6.2 Clock Management Registers

3.6.2.1 System Clock Control Registers

3.6.2.1.1 PRM_CLKSRC_CTRL (Clock Source Control Register)

The clock source control register is dedicated to the clock source controls of the device. It contains the following bit fields:

- SYSCLKSEL: Indicates the oscillator mode (oscillator/bypass) and is automatically updated at power up
- AUTOEXTCLKMODE: Enables autogating for the system clock, depending on the device power state. The clock can be configured to be automatically gated when all power domains are in either off or retention state. When the gating condition is satisfied, the internal oscillator is turned off, if it is used. Otherwise, sys_clkreq is asserted to notify the external clock source to turn off.

NOTE: Power consumption is reduced with the SYS_CLK off; however, wake-up latency is increased because of oscillator stabilization time after the clock is turned on again.

- SYSCLKDIV: Input divider (1, 2) of the system clock

3.6.2.1.2 PRM_CLKSETUP (Source-Clock Setup Register)

The source-clock setup register allows the setting of the setup time of the oscillator system clock, based on the number of 32-kHz clock cycles. This duration corresponds to the time required by the oscillator to stabilize before propagating the system clock.

Because the reset lasts long enough for oscillator stabilization, this register is not used at power-on reset of the device. This is ensured either by the external reset source (power IC) or by the reset extension in the PRCM module (RSTTIME0 timer). The PRM_CLKSETUP register is cleared on cold reset only.

NOTE: The clock setup time is implemented using the oscillator mode or the external clock mode (bypass mode). (The mode of the oscillator is selected by the SYSCLKSEL bits in the PRM_CLKSRC_CTRL register).

3.6.2.1.3 PRM_CLKSEL (Source-Clock Selection Register)

The PRCM.PRM_CKSEL[2:0] SYS_CLKIN_SEL bit field is used to select the input frequency of the system clock (12, 13, 16.8, 19.2, 26 or 38.4 MHz).

3.6.2.2 External Clock Output Control Registers

3.6.2.2.1 PRM_CLKOUT_CTRL (Clock Out Control Register)

The PRM clock out control register provides control to enable and disable the gating of the sys_clkout1 output clock.

3.6.2.2.2 CM_CLKOUT_CTRL (Clock Out Control Register)

The CM clock out control register provides control over the device output clock sys_clkout2, which can be used externally for functional or test purposes. The register allows the following:

- Selection of the source clock for sys_clkout2:
  - CORE_CLK
  - CM_SYS_CLK
  - 96-MHz clock
  - 54-MHz clock
- Dividing-down the selected source clock by 1, 2, 4, 8, or 16
- Enabling/disabling of the gating of sys_clkout2

3.6.2.3 DPLL Clock Control Registers

A set of registers controls the clock features of the five DPLLs (DPLL1, DPLL2, DPLL3, DPLL4, and DPLL5):

- CM_CLKSELn_PLL_<processor_name>
- CM_CLKSELn_PLL
- CM_CLKEN_PLL_<processor_name>
- CM_CLKEN_PLL
- CM_AUTOIDLE_PLL_<processor_name>
- CM_AUTOIDLE_PLL
- CM_IDLEST_PLL_<processor_name>
- CM_IDLEST_CKGEN
- CM_IDLEST2_CKGEN

The following sections describe the purposes of these registers.

3.6.2.3.1 CM_CLKSELn_PLL_ <processor_name> (Processor DPLL Clock Selection Register)

The processor DPLL clock selection register controls the clock configuration of DPLL1 and DPLL2, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Selection of the fast bypass clock (CORE_CLK or CORE_CLK/2) in bypass mode
- Configuration of DPLL output clock divider values (M2 factor)

The device has four DPLL clock selection registers for DPLL1 and DPLL2:

- CM_CLKSEL1_PLL_MPU: DPLL1 multiplier, divider, and fast bypass clock selection
- CM_CLKSEL2_PLL_MPU: DPLL1 output clock divider selection
- CM_CLKSEL1_PLL_IVA2: DPLL2 multiplier, divider, and fast bypass clock selection
- CM_CLKSEL2_PLL_IVA2: DPLL2 output clock divider selection

3.6.2.3.2 CM_CLKSELn_PLL (DPLL Clock Selection Register)

The DPLL clock selection register controls the clock configuration for DPLL3, DPLL4, and DPLL5, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Configuration of DPLL output clock divider values

The device has the following DPLL clock selection registers for DPLL3, DPLL4, and DPLL5:

- CM_CLKSEL1_PLL: DPLL3 multiplier, divider, and output clock division configuration. Source selection for the 54-MHz and 48-MHz clock (48M_FCLK) between DPLL4 output and sys_altclk.
- CM_CLKSEL2_PLL: DPLL4 multiplier and divider configuration
- CM_CLKSEL3_PLL: Divider configuration for 96-MHz clock (96M_FCLK)
- CM_CLKSEL4_PLL: DPLL5 multiplier and divider configuration

- CM_CLKSEL5_PLL: Divider configuration for 120-MHz clock (120M_FCLK)

3.6.2.3.3 CM_CLKEN_PLL_<processor_name> (Processor DPLL Clock Enable Register)

The processor DPLL clock enable register allows the enabling or disabling of DPLL1 and DPLL2. It allows an immediate setting of the DPLL.

The device has two DPLL clock enable registers, one for DPLL1 and one for DPLL2:

- CM_CLKEN_PLL_MPU: DPLL1 (MPU)
- CM_CLKEN_PLL_IVA2: DPLL2 (IVA2)

The CM_CLKEN_PLL_<processor_name> register allows programmable control of the following DPLL features:

- Low-power stop mode (only for DPLL2)/low-power bypass mode/lock mode selection
- Automatic recalibration enable/disable
- Programmable internal frequency range of the DPLL
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transitions:
  - From bypass to lock
  - From stop mode to lock
  - From lock to relock

NOTE: DPLL1 enters its internal power state (MNBYPASS) after being released from reset or when a multiplier value of 0 or 1 is loaded into the DPLL. Therefore, even if the CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL bit field is reset to the low-power bypass mode, DPLL1 automatically transitions to MNBYPASS mode, because the multiplier value (the CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT bit field) resets to 0.

3.6.2.3.4 CM_CLKEN_PLL (DPLL Enable Register)

The DPLL enable register allows control of DPLL3, DPLL4, and DPLL5. It allows an immediate setting of the DPLLs. This register controls the following features of the two DPLLs:

- DPLL operation mode:
  - Low-power bypass, fast-relock bypass, and lock modes for DPLL3
  - Low-power bypass and lock modes for DPLL4
- Programmable automatic recalibration
- Programmable internal frequency range for the DPLL
- The DPLL3 output M3X2 and the DPLL4 outputs M2, M3, M4, M5, and M6 clock paths can be powered down. However, the setting takes effect only when the output clock is gated. It is also powered down whenever the DPLL is in stop mode, regardless of the software settings.
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transition:
  - From bypass to lock
  - From stop mode to lock
  - From lock to relock

3.6.2.3.5 CM_AUTOIDLE_PLL_ <processor_name> (Processor DPLL Autoidle Register)

The processor DPLL autoidle register allows the enabling/disabling of the automatic processor DPLL activity control. In automatic mode, the DPLL automatically enters low-power stop mode when the DPLL clock is not required. It is also restarted automatically.

The following are the device DPLL autocontrol registers:

- CM_AUTOIDLE_PLL_MPU: DPLL1 autoidle mode control

- CM_AUTOIDLE_PLL_IVA2: DPLL2 autoidle mode control

3.6.2.3.6 CM_AUTOIDLE_PLL (DPLL Autoidle Register)

The DPLL autoidle register allows the enabling/disabling of the automatic mode-switching control for DPLL3 and DPLL4. This automatic mode takes effect only when the DPLLs are locked.

DPLL3 can be configured to automatically switch to either low-power bypass mode or low-power stop mode when the CORE power domain clock is not required.

DPLL4 can be configured to automatically switch to low-power stop mode when the PER power domain clock is not required.

3.6.2.3.7 CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register)

The DPLL5 autoidle register allows the enabling/disabling of the automatic mode-switching control. This automatic mode takes effect only when the DPLL is locked.

When enabled, DPLL5 is automatically switched to low-power stop mode whenever the 120-MHz output clock is gated.

3.6.2.3.8 CM_IDLEST_CKGEN (Source-Clock Idle-Status Register)

The source-clock idle-status register provides a status of DPLL3 and DPLL4 clock activity. It also provides the status of the functional clocks derived from DPLL4 output.

The activity status for DPLL3 and DPLL4 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The functional 96-MHz clock is active, or not.
- The functional 48-MHz clock is active, or not.
- The functional 12-MHz clock is active, or not.
- The functional 54-MHz clock is active, or not.

The functional 96-MHz clock and all other functional clocks derived from it are active only when DPLL4 is locked and the clock is required.

The functional 48-MHz and 12-MHz clocks are qualified as active only if the clock is required and when the external alternate clock is selected as the source clock.

The functional 54-MHz clock (DSS_TV_CLK) is active only when DPLL4 is locked, selected as the source clock, and required.

3.6.2.3.9 CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register)

The source-clock idle-status register provides the status of DPLL5 clock activity. It also provides the status of the functional clocks derived from DPLL5 output.

The activity status for DPLL5 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The 120-MHz functional clock is active, or not.
- The output stage of the 120-MHz functional clock is active, or not.

3.6.2.3.10 CM_IDLEST_PLL_ <processor_name> (Processor DPLL Idle-Status Register)

The processor DPLL idle-status register indicates the status of the processor DPLL: whether it is in locked or bypass mode.

The device DPLL idle-status registers are:

- CM_IDLEST_PLL_MPU: DPLL1 activity status
- CM_IDLEST_PLL_IVA2: DPLL2 activity status

3.6.2.4 Power-Domain Clock Control Registers

An identical set of registers controls the clock features of the power domains in the device:

- CM_CLKSEL_<domain_name>
- CM_FCLKEN_<domain_name>
- CM_ICLKEN_<domain_name>
- CM_AUTOIDLE_<domain_name>
- CM_IDLEST_<domain_name>
- CM_CLKSTCTRL_<domain_name>
- CM_CLKSTST_<domain_name>
- CM_SLEEPDEP_<domain_name>

The following sections describe the purposes of these registers.

3.6.2.4.1 CM_CLKSEL_ <domain_name> (Clock Select Register)

The clock select register controls the selection of the module or subsystem input clock frequency (except for the processor modules). Therefore, it deals only with modules or subsystems for which the frequency is scalable or selectable (the others have fixed and nonprogrammable frequencies). Both functional and interface clocks can be scaled. In most cases, their value is a divided value from the DPLL3 (CORE) or the DPLL4 (PER) output clock.

The device includes the following clock select registers:

- CM_CLKSEL_CORE: L3 and L4 interconnects, and GPTIMER10 and 11 functional clocks
- CM_CLKSEL_CAM: Camera subsystem functional clock
- CM_CLKSEL_DSS: DSS functional clock 1 and TV functional clock
- CM_CLKSEL_PER: GPTIMER2, 3, 4, 5, 6, 7, 8, and 9 functional clocks
- CM_CLKSEL_SGX: SGX subsystem functional clock
- CM_CLKSEL_WKUP: GPTIMER1 functional clock and reset manager counter clock

The 32-kHz functional clock (32K_FCLK) is selected when the device enters off mode. The functional clock of the GPTIMER1 is selectable between the always-on 32K_FCLK and the system clock (SYS_CLK), but it is used with the 32-kHz clock.

The CM_CLKSEL_SGX register controls the SGX functional clock source and divider ratio, which is divided from the CORE_CLK source clock or COREX2_CLK. Table 3-88 summarizes SGX_FCLK frequency for different configurations of the register field.

Table 3-88. GFX Functional Clock Ratio Settings

CM_CLKSEL_SGX.CLKSEL_SGX	SGX_L3_FCLK
0x0	CORE_CLK/3
0x1	CORE_CLK/4
0x2	CORE_CLK/6
0x3	CM_96M_FCLK
0x4	SGX_192M_FCLK
0x5	CORE_CLK/2
0x6	COREX2_CLK/3
0x7	COREX2_CLK/5

3.6.2.4.2 CM_FCLKEN_ <domain_name> (Functional Clock Enable Register)

The functional clock enable register allows control of the functional clock activity of each module or subsystem. All module functional clocks are controllable by software, except for the MPU, interconnect, and memory subsystems, for which the clocks are automatically controlled by the PRCM.

The device has the following functional clock control registers:

- CM_FCLKEN1_CORE and CM_FCLKEN3_CORE: CORE domain peripherals set
- CM_FCLKEN_CAM: Camera subsystem
- CM_FCLKEN_DSS: DSS subsystem
- CM_FCLKEN_PER: PER domain peripherals set
- CM_FCLKEN_IVA2: IVA2.2 subsystem
- CM_FCLKEN_SGX: SGX subsystem
- CM_FCLKEN_WKUP: WKUP domain peripherals set
- CM_FCLKEN_USBHOST: HS USB Host subsystem

The software effect is immediate and direct. The functional clock is turned on as soon as the bit is set, and turned off if the bit is cleared and the clock is not required by any module. On module wakeup, the functional clock can be automatically restarted.

NOTE: The functional clock supplies the functional part of a module or subsystem, which is not operational without its functional clock. In some cases, a module or a subsystem may require multiple functional clocks.

3.6.2.4.3 CM_ICLKEN_ <domain_name> (Interface Clock Enable Register)

The interface clock enable register allows control of the interface clock activity of each module or subsystem. This register provides control over each module in the device.

The device has following interface clock control registers:

- CM_ICLKEN1_CORE and CM_ICLKEN3_CORE: CORE domain peripherals set
- CM_ICLKEN_CAM: Camera subsystem
- CM_ICLKEN_DSS: DSS subsystem
- CM_ICLKEN_PER: PER domain peripherals set
- CM_ICLKEN_SGX: SGX subsystem
- CM_ICLKEN_WKUP: WKUP domain peripherals set
- CM_ICLKEN_USBHOST: HS USB Host subsystem

This register has an immediate effect, causing the source of the interface clock to be effectively cut (if the appropriate bit is cleared and no module requires this clock) or activated (if the appropriate bit is set).

Independent functional and interface clock control registers provide potential power savings for each module. For example, because the configuration port and interface of the module are still active, disabling a functional clock of a module while keeping its interface clock active (leaving the module inactive but allowing access to its registers) reduces power consumption.

When the interface clock is disabled, the module cannot communicate with the reset of the device; therefore, it is in idle mode. For example, the interface clock of a peripheral can be disabled while its functional clock is active; it is then idled, from the device standpoint, while it can detect any external event. This configuration typically allows a main part of the device to go into idle mode while keeping a peripheral active and ready to wake up from an external event.

Because a module may or may not be able to function without its functional or interface clocks, power-management strategies must be adapted accordingly. This relation is programmable and is defined in the CLOCKACTIVITY bits of the module SYSCONFIG register; therefore, it requires consistent programming of the CM_FCLKEN and CM_ICLKEN registers.

NOTE: The interface clock ensures proper communication between any module and the interconnect (L3 or L4), in most cases supplying the module interface and registers.

3.6.2.4.4 CM_AUTOIDLE_ <domain_name> (Autoidle Register)

The autoidle register holds an AUTOIDLE bit per module that belongs to the related power domain. Each AUTOIDLE bit enables/disables automatic (hardware) gating of a module interface clock.

When AUTOIDLE and ICLKEN are set for a module, the module interface clock is managed automatically (that is, by hardware control) according to the power domain clock activity; for example, stopped before a power domain sleep transition and reenabled on wakeup. Table 3-89 lists the possible autoidle settings for the interface clock.

Table 3-89. Interface Clock Autoidle Settings

CM_AUTOIDLE.AUTO_<module>	CM_ICLKEN.EN_<module>	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

The device has the following autoidle control registers:

- CM_AUTOIDLE1_CORE and CM_AUTOIDLE3_CORE: CORE domain peripherals set
- CM_AUTOIDLE_CAM: Camera subsystem
- CM_AUTOIDLE_DSS: DSS subsystem
- CM_AUTOIDLE_PER: PER domain peripherals set
- CM_AUTOIDLE_WKUP: WKUP domain peripherals set
- CM_AUTOIDLE_USBHOST: HS USB Host subsystem

NOTE: For SmartReflex1 and 2, IVA2.2, and GFX modules, the automatic idle mode is always enabled, and is not software-controllable.

3.6.2.4.5 CM_IDLEST_ <domain_name> (Idle-Status Register)

The idle-status register allows checking whether a target module is in idle mode or if an initiator module is in standby mode. The software should not access a target module in idle mode. A target access in this state can lead to an error.

The idle mode of any module can depend on the configuration of the CM_FCLKEN_<domain_name> and CM_ICLKEN_<domain_name> registers, or may be controlled automatically by hardware, depending on the configuration of the CM_AUTOIDLE_<domain_name> registers.

In the case of IVA2.2 subsystem, standby mode is reached after the IVA2.2 processor has performed its idle instruction.

The device has the following idle status registers:

- CM_IDLEST_MPU: MPU subsystem
- CM_IDLEST1_CORE and CM_IDLEST3_CORE: CORE domain peripherals set
- CM_IDLEST_CAM: Camera subsystem
- CM_IDLEST_DSS: DSS
- CM_IDLEST_PER: Peripheral domain peripherals set
- CM_IDLEST_NEON: NEON subsystem
- CM_IDLEST_IVA2: IVA2.2 subsystem
- CM_IDLEST_SGX SGX subsystem
- CM_IDLEST_WKUP: WKUP domain peripherals set
- CM_IDLEST_USBHOST: HS USB Host subsystem

3.6.2.4.6 CM_CLKSTCTRL_ <domain_name> (Clock State Control Register)

The clock state control register holds a CLKTRCTRL_<clock domin> bit field for each clock domain in the power domain. It controls the hardware- and software-supervised state transitions between active and inactive states. Table 3-90 lists the clock state transition settings.

Table 3-90. Clock State Transition Settings

CM_CLKSTCTRL_<pwr domain>. CLKTRCTRL_<clk domain>	Description
0x0	The automatic hardware-supervised mode is disabled. The clocks in a clock domain cannot be cut automatically. This prevents any power transition on the power domain.
0x1	Starts software-supervised (forced) sleep transition on the domain. All clocks in the clock domain are automatically cut whenever the initiators in the modules are in standby mode.
0x2	Starts software-supervised (forced) wake-up transition on the domain. The clocks in the clock domain are restarted.
0x3	The automatic hardware-supervised mode is enabled, and the clocks in the clock domain are automatically cut whenever the modules and subsystem in the clock domain are in idle or standby mode and the domain dependencies are met.

The hardware-supervised mode and the software-supervised (forced) sleep mode are mutually exclusive. It is a software decision to program one mode or another, and the software programs the PRCM module accordingly.

The hardware-supervised mode is coupled to the sleep and wake-up dependencies programmed in the PRCM module, whereas the software-supervised mode must be independent of those dependencies. Therefore, the sleep and wake-up dependencies must be disabled before the software forces a sleep transition on a power domain; otherwise, the forced-domain will be wakened immediately because of the wake-up dependency.

The device has the following clock state control registers:

- CM_CLKSTCTRL_MPU: MPU subsystem clock domain
- CM_CLKSTCTRL_CORE: L3, L4, and D2D clock domains
- CM_CLKSTCTRL_CAM: Camera subsystem clock domain
- CM_CLKSTCTRL_DSS: DSS clock domain
- CM_CLKSTCTRL_PER: Peripherals clock domain
- CM_CLKSTCTRL_NEON: NEON clock domain
- CM_CLKSTCTRL_IVA2: IVA2.2 clock domain
- CM_CLKSTCTRL_SGX: Graphics clock domain
- CM_CLKSTCTRL_EMU: Emulation clock domain
- CM_CLKSTCTRL_USBHOST: HS USB Host clock domain

The CORE domain has three clock domains (L3, L4, and D2D); it does not have forced sleep and forced wake-up ability.

Although the sleep transition in the MPU power domain cannot be initiated by software using this register, a software-initiated forced wake-up capability exists. This can be used to wake up the MPU power domain if it does not wake up when the CORE power domain wakes up (the MPU wake-up-dependency PM_WKDEP_MPU[0] EN_CORE bit is set to 0).

If the hardware-supervised mode is enabled, the following occur:

- The MPU domain clock is automatically cut if the MPU executes the wait-for-interrupt instruction.
- The IVA2 domain clock is automatically cut when the DSP completes its idle procedure, and the IVA2.2 subsystem is ready for standby.
- The L3 domain clock is automatically cut when all initiators are in standby mode and slave ports are idled.
- The L4 domain clock is automatically cut when all peripherals and slave ports are idled.
- The DSS interface clock is automatically cut when it stops fetching data from the frame buffer (provided the MPU is also in standby mode, if sleep dependency in the MPU power domain is

enabled). The display functional clock is controlled only by the CM_FCLKEN_DSS register.

- The PER domain clock is automatically cut when all initiators are in standby mode and all slave ports are in idle (provided the MPU and the DSP are in standby mode and the CORE power domain is inactive, if sleep dependency in their domains is enabled).
- The USBHOST power domain clock is automatically cut whenever the USBHOST is in standby mode (provided MPU is also in standby mode, if sleep dependency in the MPU domain is enabled, and IVA2 is also in standby mode, if sleep dependency in the IVA2 domain is enabled).
- Because of the hardwired sleep dependency between NEON and the MPU domain, NEON can go into idle only if the MPU goes into standby mode. The MPU domain must also be configured in automatic hardware supervised mode for the NEON power domain idle transition to occur.

3.6.2.4.7 CM_CLKSTST_ <domain_name> (Clock State Status Register)

The clock state status register logs the activity status of the power domain clock. This includes the activity of the interface clocks running only on the domain.

The device has following clock state status registers:

- CM_CLKSTST_MPU: MPU subsystem clock activity
- CM_CLKSTST_CORE: L3 clock domain activity and L4 clock domain activity
- CM_CLKSTST_CAM: Camera subsystem clock activity
- CM_CLKSTST_DSS: DSS clock activity
- CM_CLKSTST_PER: PER clock domain activity
- CM_CLKSTST_IVA2: IVA2.2 clock domain activity
- CM_CLKSTST_SGX: Graphics subsystem clock activity
- CM_CLKSTST_EMU: Emulation clock activity
- CM_CLKSTST_USBHOST: USBHOST clock activity

3.6.2.4.8 CM_SLEEPDEP_ <domain_name> (Sleep Dependency Control Register)

The sleep dependency control register allows the enabling or disabling of the sleep transition dependency of a power domain with respect to other power domains.

The device has following sleep dependency registers:

- CM_SLEEPDEP_CAM: CAM power domain sleep dependency with the MPU power domain
- CM_SLEEPDEP_DSS: Display power domain sleep dependency with the MPU power domain and the IVA2 power domain
- CM_SLEEPDEP_PER: PER power domain sleep dependencies with the MPU, IVA2, and CORE power domains
- CM_SLEEPDEP_SGX: SGX power domain sleep dependency with the MPU power domain
- CM_SLEEPDEP_USBHOST: USBHOST power domain sleep dependency with the MPU and IVA2 power domains

Although the CORE power domain is composed of L3 and L4 clock domains, the sleep dependency with the L3 clock domain is always enabled (not programmable by software); there is no sleep dependency between the PER power domain and the CORE_L4 clock domain.

The dependencies listed in Table 3-91 can be enabled or disabled by software.

Table 3-91. Sleep Dependency Settings

		Parent Domain		
Dependent Domain		**MPU**	**IVA2**	**CORE-L3**
CAM		Software controlled		
DSS		Software controlled	Software controlled	
PER		Software controlled	Software controlled	Always enabled
SGX		Software controlled		
USBHOST		Software controlled	Software controlled	

3.6.2.5 Domain Wake-Up Control Registers

The following modules have programmable wake-up control:

- CORE power domain:
  - USBTLL
  - HS USB OTG
  - McBSP 1 and 5
  - GPTIMER[10,11]
  - UART[1,2]
  - I2C[1..3]
  - McSPI[1..4]
  - MMC[1,2,3]
- PER power domain:
  - McBSP[2..4]
  - GPTIMER[2..9]
  - UART [3,4]
  - WDTIMER3
  - GPIO[2..6]
- WKUP power domain:
  - GPTIMER1
  - GPIO1
  - SR[1,2]
  - I/O pad
- DSS power domain:
  - DSS subsystem
- USBHOST power domain:
  - HS USB Host subsystem

The registers in the following sections control the wake-up settings.

3.6.2.5.1 PM_WKEN_ <domain_name> (Wake-Up Enable Register)

The wake-up enable register applies only to modules that can generate wake-up events. It allows the enabling or disabling of the wakeup of the related power domain on a module or subsystem wake-up event. Each EN_<module> bit in the register enables/disables the wake-up event from the module to the PRCM module.

The device has the following wake-up enable registers:

- PM_WKEN1_CORE and PM_WKEN3_CORE: CORE domain modules wake-up control
- PM_WKEN_DSS: Display subsystem (DSS) wake-up control
- PM_WKEN_PER: Peripheral domain modules wake-up control
- PM_WKEN_WKUP: WKUP domain modules wake-up control
- PM_WKEN_USBHOST: HS USB Host subsystem wake-up control

NOTE: The wake-up signals issued from the MPU and IVA2.2 INTCs are nonmaskable in the PRCM module. However, they cannot be generated if the corresponding interrupts are masked in the INTCs.

3.6.2.5.2 PM_WKST_ <domain_name> (Wake-Up Status Register)

The wake-up status register logs wake-up events from all modules. Each ST_<module> bit of this register logs a given module-generated wake-up event.

The device has the following wake-up status registers:

- PM_WKST1_CORE and PM_WKST3_CORE: CORE domain modules wake-up event status
- PM_WKST_PER: Peripheral domain modules wake-up event status
- PM_WKST_WKUP: WKUP domain modules wake-up event status
- PM_WKST_USBHOST: HS USB Host subsystem wake-up control

The functional clock of the module causing the wakeup automatically restarts on the wakeup, but the software must enable the functional clock (CM_FCLKEN_<domain_name> register) before clearing the wake-up status bit.

NOTE:

- Software must clear this register before a new sleep transition request; otherwise, the register prevents the sleep transition from occurring.
- If the PRM interrupt is enabled on a module wakeup, the PM_WKST_<domain_name> must be cleared before clearing the PRM_IRQSTATUS_<processor_name> interrupt status register.

3.6.2.5.3 PM_WKDEP_ <domain_name> (Wake-Up Dependency Register)

The wake-up dependency register allows the enabling/disabling of a wake-up dependency between power domains. When a domain wakes up, it can wake up another domain.

The device has the following wake-up dependency registers:

- PM_WKDEP_MPU: MPU power domain wake-up dependency with the following domains:
  - CORE
  - IVA2
  - WKUP
  - DSS
  - PER
- PM_WKDEP_DSS: DSS power domain wake-up dependency with the following domains:
  - MPU
  - IVA2
  - WKUP
- PM_WKDEP_CAM: The CAM power domain has programmable wake-up dependency with the following domains:
  - MPU
  - IVA2
  - WKUP
- PM_WKDEP_PER: The PER power domain has programmable wake-up dependency with the following domains:
  - MPU
  - IVA2
  - WKUP
  - CORE

  The PER power domain can be wakened only by a wakeup of the L3 and D2D clock domains, not by an L4 clock domain.
- PM_WKDEP_NEON: The NEON power domain has programmable wake-up dependency with the following domain:
  - MPU
- PM_WKDEP_IVA2: The IVA2 power domain has programmable wake-up dependency with the following domains:
  - MPU
  - PER
  - WKUP

  - CORE
- PM_WKDEP_SGX: The SGX power domain has programmable wake-up dependency with the following domains:
  - MPU
  - IVA2
  - WKUP
- PM_WKDEP_USBHOST: The USBHOST power domain has programmable wake-up dependency with the following domains:
  - MPU
  - IVA2
  - WKUP
  - CORE

There is no wake-up dependency control for the WKUP power domain, because it is always on.

Because the CORE power domain wake-up dependencies are not programmable, the CORE power domain always wakes up on a wake-up event on the following domains:

- MPU
- IVA2
- WKUP
- CAM
- DSS
- SGX
- PER
- USBHOST

3.6.2.5.4 PM_ <processor_name> GRPSEL_ <domain_name> (Processor Group Selection Register)

The processor group selection register allows defining the group of modules in the domain that can wake up a processor domain (MPU or IVA2). This bit is effective only if the module wake-up capability is enabled (PM_WKEN_<domain_name> register).

The device has the following processor group selection registers:

- PM_MPUGRPSEL1_CORE and PM_MPUGRPSEL3_CORE: CORE power domain modules MPU wake-up control
- PM_IVA2GRPSEL1_CORE and PM_IVA2GRPSEL3_CORE: CORE power domain modules IVA2 wake-up control
- PM_MPUGRPSEL_PER: PER power domain modules MPU wake-up control
- PM_IVA2GRPSEL_PER: PER power domain modules IVA2 wake-up control
- PM_MPUGRPSEL_WKUP: WKUP power domain modules MPU wake-up control
- PM_IVA2GRPSEL_WKUP: WKUP power domain modules IVA2 wake-up control
- PM_MPUGRPSEL_USBHOST: HS USB Host subsystem MPU wake-up control
- PM_IVA2GRPSEL_USBHOST: HS USB Host subsystem IVA2 wake-up control

NOTE: The wake-up capability of the DSS is always attached to the MPU group; it cannot be attached to the IVA2.2, and therefore is not programmable.

3.6.3 Reset Management Registers

3.6.3.1 Reset Control

3.6.3.1.1 PRM_RSTTIME (Reset Time Register)

The reset time register provides control over reset duration. Two durations are configurable:

- RSTTIME1: Minimum duration (by default, two cycles of the 32-kHz clock) of the global warm reset (sys_nreswarm) assertion for external devices, such as flash memories. At power-up reset, DPLLs are reset and the power domains are switched on and stabilized during this duration.
- RSTTIME2: Minimum duration (by default, 16 cycles of the RM_ICLK clock) to control power domain resets when the domain clocks are on.

For global cold and warm resets, the reset is applied for the RSTTIME1 + RSTTIME2 duration. In the other cases, when a power domain individually goes from off to active, the reset is applied only for the RSTTIME2 duration (plus the power domain wake-up duration).

RSTTIME1 and RSTTIME2 can be reprogrammed for different behavior after the initial power up.

3.6.3.1.2 RM_RSTCTRL_ <domain_name> (Reset Control Register)

The reset control register provides control over the local domain software reset.

Most device modules include an individual software reset that can be controlled using the related module SYS_CONFIG register.

The RM_RSTCTRL_<domain_name> register is used for specific subsystems or modules that do not support this local reset or that require a specific system control (the IVA2.2 subsystem).

The PRM_RSTCTRL register also handles the global software warm reset control.

The device includes the following reset control registers:

- PRM_RSTCTRL: This register allows control of the assertion of the global software reset and the DPLL3 software reset. These bits are automatically cleared. Assertion of the DPLL3 software reset triggers a device global cold reset. The reset condition of this register depends on the bit field:
  - The RST_GS bit is set on any global source of reset (warm or cold).
  - The RST_DPLL3 bit is set only on a global cold source of reset.
- RM_RSTCTRL_IVA2: IVA2 power domain software resets the IVA2.2 and SEQ subsystems. Both subsystems are held under reset after power up and are released by software. The SEQ software reset bit is reset to 1 (SEQ reset active) on an IVA2 domain power transition from off or retention to on.

3.6.3.1.3 RM_RSTST_ <domain_name> (Reset Status Register)

The reset status register logs any source that has generated a reset in the related power domain. Depending on the domain, several causes of reset can be logged:

- Global device cold reset
- Global device warm reset
- Power domain transition (off to active, and inactive to active)
- Software reset
- Processor emulation reset

The PRM_RSTST register logs the source of the global reset:

- VDD1/VDD2 voltage manager reset
- External warm reset
- MPU watchdog reset
- Global software reset and DPLL3 software reset
- Global cold reset

The device includes the following reset status registers:

- RM_RSTST_MPU
- RM_RSTST_CORE
- RM_RSTST_DSS
- RM_RSTST_CAM
- RM_RSTST_IVA2
- RM_RSTST_PER
- RM_RSTST_NEON

- RM_RSTST_SGX
- RM_RSTST_EMU
- PRM_RSTST
- RM_RSTST_USBHOST

Only the RM_RSTST_CORE, RM_RSTST_IVA2, and PRM_RSTST registers log software sources of reset.

Each bit of these registers is set on the effective release of the respective reset signal.

3.6.4 Power Management Registers

3.6.4.1 PM_PWSTCTRL_ <domain_name> (Power State Control Register)

The power state control register allows controlling the power state transition of the domain.

This register holds the following bit fields:

- POWERSTATE: Power state (ON, retention, or off) to be applied for the next transition
- LOGICRETSTATE: Logic is retained or switched off when the domain goes into retention. This feature is domain-dependent and is not necessarily programmable (read only).
- MEMRETSTATE[1 to X]: Memory block i is retained (RAM state retained) or switched off (RAM state not retained) when the domain goes into retention. This feature is domain-dependent and is not necessarily programmable (read only).
- MEMONSTATE[1 to X]: Memory block i in the domain is on (RAM active), retained (RAM inactive but state retained) or switched off (RAM state not retained) when the domain is on. This feature is domain-dependent and is not necessarily programmable (read only).
- MEMORYCHANGE: Allows updating the memory state according to latest MEMONSSTATE[1 to X] setting.

The device has the following power state control registers:

- PM_PWSTCTRL_MPU: MPU domain power management
- PM_PWSTCTRL_CORE: CORE domain power management
- PM_PWSTCTRL_SGX: SGX domain power management
- PM_PWSTCTRL_DSS: DSS domain power management
- PM_PWSTCTRL_CAM: CAM domain power management
- PM_PWSTCTRL_PER: PER domain power management
- PM_PWSTCTRL_NEON: NEON domain power management
- PM_PWSTCTRL_IVA2: IVA2 domain power management
- PM_PWSTCTRL_USBHOST: USBHOST domain power management

MPU domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- Logic and L1 cache state are switchable to off and retention states when the power domain is in retention state.
- L2 cache state is switchable to off and retention states when the power domain is in retention state.
- L2 cache state is switchable to off and on states when the power domain is in on state.
- L2 cache state can be switched dynamically when the domain state is on (no power transition is required).
- The L1 cache is always on when the power domain state is on.

CORE domain power management has the following features:

- The power state is programmable to on, retention, or off states.
- Nonretained logic is switchable to off and retention states when the power domain is in retention state.
- Memory bank 1 and 2 states are switchable to off and retention states when the power domain is in retention state.
- Memory bank 1 and 2 states are switchable to off, retention, and on states when the power domain is in on state.
- Memory bank 1 and 2 states can be switched dynamically when the domain state is on (no power transition is required).

SGX domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.
- The memory is always in retention state when the power domain is in retention state.
- The memory is always in on state when the power domain is in on state.

DSS domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.
- The memory is always in retention state when the power domain is in retention state.
- The memory is always in on state when the power domain is in on state.

CAM domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.
- The memory is always in retention state when the power domain is in retention state.
- The memory is always in on state when the power domain is in on state.

PER domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.

NEON domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.

IVA2 domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- Logic state is switchable to off and retention states when the power domain is in retention state.
- L1 cache state is switchable to off and retention states when the power domain is in retention state.
- L1 flat memory state is switchable to off and retention states when the power domain is in retention state.
- L2 cache state is switchable to off and retention states when the power domain is in retention state.
- L2 flat memory state is switchable to off and retention states when the power domain is in retention state.
- L1 cache state is always on when the power domain is in on state.
- L1 flat memory state is always on when the power domain is in on state.
- L2 cache state is switchable to off and on states when the power domain is in on state.
- L2 flat memory state is always on when the power domain is in on state.
- L2 cache memory state can be switched dynamically to off state and back to on state when the domain state is on (no domain power transition is required).

USBHOST domain power management has the following features:

- The power state is programmable to on, retention, and off states.
- The logic is always in retention state when the power domain is in retention state.
- The memory is always in retention state when the power domain is in retention state, and the memory is always on when the power domain is in on state.

The EMU power state is not programmable. The EMU domain is always powered down when the software or hardware conditions that allow a power transition are met. Thus, the EMU domain is automatically powered down after the power-up sequence if no emulation hardware is connected.

NOTE: The L1 cache memory bank can be configured to be either entirely or partially cache or flat memory. This configuration is done in the IVA2.2 subsystem. The part that is configured as cache memory can be retained; however, because tag and validity bit information are not retained in the case of L1 cache, this part cannot be retrieved after wakeup. It is important to configure the L1 cache memory state with a consistent value depending on the chosen configuration when the domain is in retention state:

- If the L1 cache memory bank is entirely configured as cache memory, set the PM_PWSTCTRL_IVA2[8] SHAREDL1CACHEFLATRETSTATE bit to the same value as the PM_PWSTCTRL_IVA2[2] LOGICRETSTATE bit.
- If the L1 cache memory bank is entirely or partially configured as flat memory, set the PM_PWSTCTRL_IVA2[8] SHAREDL1CACHEFLATRETSTATE bit to the same value as the PM_PWSTCTRL_IVA2[9] L1FLATMEMRETSTATE bit.

The same mechanism applies to the L2 cache memory bank.

Because the L2 cache may not be useful in a system when the DSP frequency and interconnect frequencies are in the same range, this memory bank can be switched off when the domain is on.

3.6.4.2 PM_PWSTST_ <domain_name> (Power State Status Register)

The power state status register provides the status of the power state transition of the domain.

This register holds the following bit fields:

- POWERSTATESTATUS: Indicates the current power state of the domain (on, retention, off)
- LOGICSTATESTATUS: Indicates the current logic power state
- MEMORYSTATESTATUS: Indicates the current memory power state
- INTRANSITION: Indicates an ongoing power state transition from ON power state to inactive, off, or retention, and from inactive, off, or retention power states to on power state

The memory power state is updated by performing a dynamic memory change (the PM_PWSTCTRL_<domain_name> MEMORYCHANGE bit). Software clears the PM_PREPWST_<domain_name> register (this forces a memory change to the same value).

The device has the following power state status registers:

- PM_PWSTST_MPU: MPU domain power state status
- PM_PWSTST_CORE: CORE domain power state status
- PM_PWSTST_SGX: SGX domain power state status
- PM_PWSTST_DSS: DSS domain power state status
- PM_PWSTST_CAM: CAM domain power state status
- PM_PWSTST_PER: PER domain power state status
- PM_PWSTST_NEON: NEON domain power state status
- PM_PWSTST_EMU: EMU domain power state status
- PM_PWSTST_IVA2: IVA2 domain power state status
- PM_PWSTST_USBHOST: USBHOST domain power state status

The MPU domain power state status register indicates the current domain, logic, L1 cache (on or off), and L2 cache (on, retention, or off) power state.

The CORE domain power state status register indicates the current domain, logic (on or off), and memory banks 1 and 2 (on, retention, or off) power state.

The SGX, DSS, CAM, PER, NEON, USBHOST, and EMU domain power state status registers indicate the current domain (on, inactive, retention, or off) power state or that the power domain transition is in progress. Because the SGX memory state is not programmable and reflects the power state, the SGX power domain does not require a memory power state.

The IVA2 domain power state status register indicates the current domain (on, inactive, retention, or off), logic (on or off), L1 cache and flat memory (on, retention, or off), L2 cache and flat memory (on, retention, or off) power state status.

3.6.4.3 PM_PREPWSTST_ <domain_name> (Previous Power State Status Register)

The previous power state status register indicates the power state entered during the last sleep transition. The information in this register is useful when the domain switches back to on state (following a wake-up transition). This register must only be read when the domain power state is on.

This register has the following bit fields:

- LASTPOWERSTATEENTERED: Last domain power state entered after the last sleep transition
- LASTLOGICSTATEENTERED: Last logic power state entered after the last sleep transition
- LASTMEMORYSTATEENTERED: Last memory power state entered after the last sleep transition or before the last memory change update

The device has the following previous power state status registers:

- PM_PREPWSTST_MPU: The MPU power domain previous power state status
- PM_PREPWSTST_CORE: The CORE power domain previous power state status
- PM_PREPWSTST_SGX: The SGX power domain previous power state status
- PM_PREPWSTST_DSS: The DSS power domain previous power state status
- PM_PREPWSTST_CAM: The CAM power domain previous power state status
- PM_PREPWSTST_PER: The PER power domain previous power state status
- PM_PREPWSTST_NEON: The NEON power domain previous power state status
- PM_PREPWSTST_IVA2: The IVA2 power domain previous power state status
- PM_ PREPWSTST_USBHOST: The USBHOST power domain previous power state status

The previous power state status register for the MPU power domain indicates the previous domain, logic, L1 cache (on or off), and L2 cache (on, retention, or off) power state.

The previous power state status register for the CORE power domain indicates the previous domain, logic (on or off), and memory banks 1 and 2 (on, retention, or off) power state.

The previous power state status registers for the SGX, DSS, CAM, PER, NEON, USBHOST and EMU power domains indicate the previous domain (on, inactive, retention, or off) power state. The SGX power domain does not require a memory power state status, because the SGX memory state is not programmable and reflects the power state.

The previous power state status register for the IVA2 power domain indicates the previous domain (on, inactive, retention, or off), logic (on or off), L1 cache and flat memory (on, retention, or off), and L2 cache and flat memory (on, retention, or off) power state status.

The current memory state depends on the setting of the PM_PWSTCTRL_<domain_name> MEMONSTATE bit during the last wake-up transition or during the last memory change operation.

This register must be cleared by software by writing any value to it; this operation must be done when the domain power state is on. Clearing this register does the following:

- Resets the PM_PREPWSTST_<domain_name> LASTPOWERSTATEENTERED bit field and the PM_PREPWSTST_<domain_name> LASTLOGICSTATEENTERED bit to the on state
- Sets the bit fields corresponding to the last memory state of the power domain to the current memory state

NOTE: Performing a memory change (the PM_PWSTCTRL_<domain_name>[3] MEMORYCHANGE bit for MPU, IVA2, and CORE) has the same effect as clearing this register.

3.6.5 Voltage Management Registers

3.6.5.1 External Voltage Control Register Descriptions

3.6.5.1.1 PRM_VOLTSETUP (Voltage Setup Time Register)

The device has two voltage setup registers:

- PRM_VOLTSETUP1
- PRM_VOLTSETUP2

These registers allow controlling the setup time of the VDD1 and VDD2 power supplies when the device exits the off mode or when the voltage is scaled. It is a constant value that depends on the connected power IC. At power-up reset, this register is not used, because the external power supply is already stable. After boot up, the software must set the correct value to ensure proper sequences when performing voltage scaling or sleep transitions.

The PRM_VOLTSETUP1 register has the following bit fields:

- SETUPTIME1: The setup time of the VDD1 regulator. It is computed as 8 x NbCycles (number of cycles of the system clock), where NbCycles is configured in the register bit field.
- SETUPTIME2: The setup time of the VDD2 regulator. It is computed as 8 x NbCycles (number of cycles of the system clock), where NbCycles is configured in the register bit field.

The PRM_VOLTSETUP1 register is used when the device exits the off mode and manages the sequencing of the voltage regulation steps (the PRM_VOLTCTRL[3] SEL_OFF bit is set to 0).

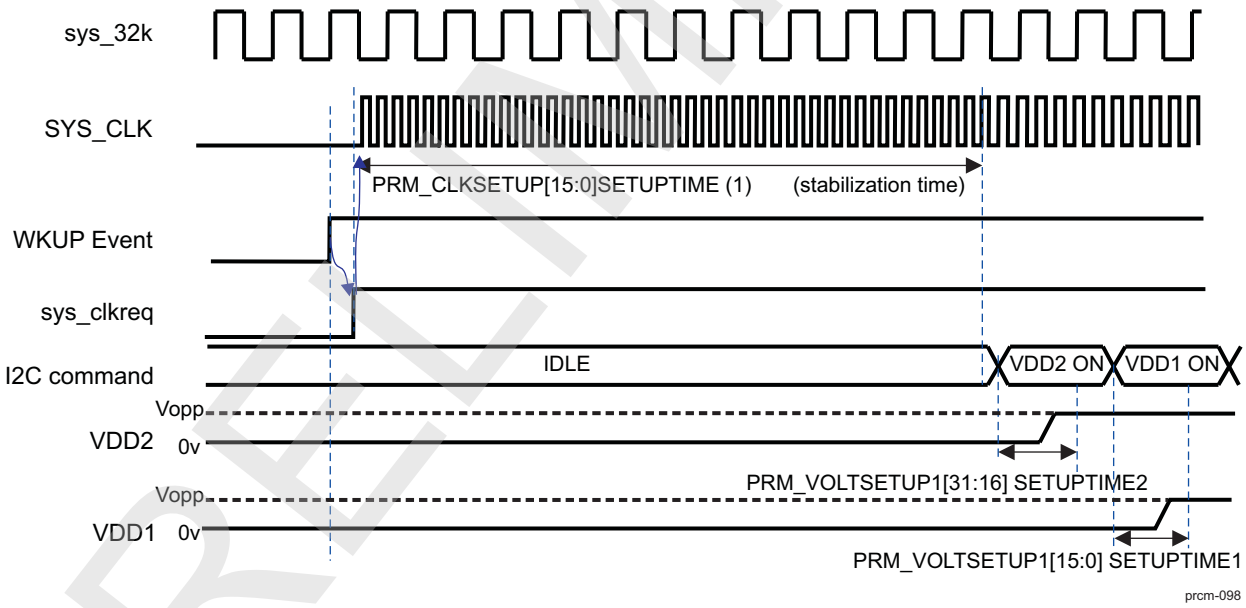
The PRM_VOLTSETUP2 register has the following bit field:

- OFFMODESETUPTIME: The number of 32-kHz clock cycles for the overall setup time of the power management IC when coming back from off mode.

The PRM_VOLTSETUP2 register is used only when the device exits off mode and an external power IC manages the sequencing of the voltages regulation steps (PRM_VOLTCTRL[3] SEL_OFF is set to 1).

Figure 3-88 shows off mode wakeup using I^2C.

Figure 3-88. Off Mode Wakeup Using I^2C



(1) PRM_VOLTSETUP1[31:16] SETUPTIME2 and PRM_VOLTSETUP1[15:0] SETUPTIME1 are not used during voltage scaling (between different OPPs).

3.6.5.1.2 PRM_VOLTOFFSET (Voltage Offset Register)

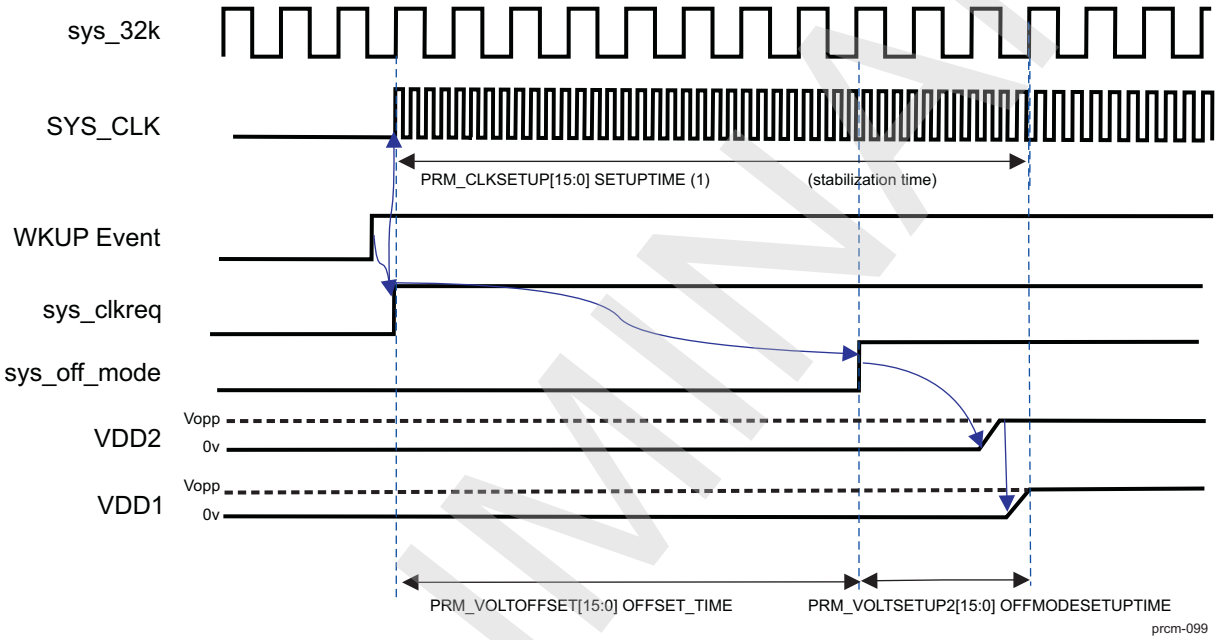
This register allows setting the offset time, which is the time duration between the assertion of sys_clkreq and the deassertion of sys_off_mode when the device is exiting off mode. This time, set as a number of 32-kHz clock cycles, is used to delay the deassertion of sys_off_mode (and as a consequence, the voltage ramping) after the clock has been requested. This is done to avoid waiting for the clock to stabilize

when the voltage is already ramped and stabilized, which would induce some leakage. Program this bit field to match the following equation: PRM_VOLTOFFSET[15:0]OFFSET_TIME = PRM_CLKSETUP[15:0]SETUPTIME – PRM_VOLTSETUP2[15:0]OFFMODESETUPTIME. This way, the voltages and clock are ready at the same time. This register is used on device wakeup from off mode when the off sequence is supervised by the power IC.

The OFFSET_TIME bit field of this register is configured as the number of 32-kHz clock cycles time delay in assertion of sys_off_mode. This register is used on device wakeup from off mode when the off sequence is supervised by the power IC.

Figure 3-89 shows off mode wakeup using SYS_OFF_MODE.

Figure 3-89. OFF Mode Wakeup Using SYS_OFF_MODE



(1) PRM_CLKSETUP[15:0] SETUPTIME is not used during device cold boot-up sequence.

3.6.5.1.3 PRM_VOLTCTRL (Voltage Source Control Register)

This register allows control of the power IC. The following are the register bit fields:

- AUTO_SLEEP: Automatically sends the sleep command when the voltage domain is in the appropriate standby mode
- AUTO_RET: Automatically sends the retention command when the voltage domain is in the appropriate standby mode
- AUTO_OFF: Automatically sends the off command when the voltage domain is in the appropriate standby mode
- SEL_OFF: Controls whether the off command is sent through the voltage controller I^2C interface or the signal sys_off_mode is asserted when entering off mode
- SEL_VMODE: Allows control of the power IC through either the voltage controller I^2C interface or the VMODE interface

3.6.5.2 Voltage Controller Registers

A specific set of registers allows control of the voltage controller. This register set provides programming flexibility to address different power IC device types through an I^2C interface.

The register set is composed of the following registers:

- Registers to store the addresses on the I^2C bus:
  - PRM_VC_SMPS_SA

  - PRM_VC_SMPS_VOL_RA
  - PRM_VC_SMPS_CMD_RA
- Registers to store the voltage values or voltage commands:
  - PRM_VC_CMD_VAL_0
  - PRM_VC_CMD_VAL_1
- Register to configure the VDD channel:
  - PRM_VC_CH_CONF
- Register to configure the I^2C interface:
  - PRM_VC_I2C_CFG
- Register to use the bypass command:
  - PRM_VC_BYPASS_VAL

3.6.5.2.1 PRM_VC_SMPS_SA (Voltage Controller SMPS Slave Address Register)

This register stores the I^2C slave address value of the power IC device. Two address values can be stored in case two different power IC chips are used to control the two VDD channels (VDD1 and VDD2).

3.6.5.2.2 PRM_VC_SMPS_VOL_RA (Voltage Controller SMPS Voltage Register Address Register)

This register stores the address value of the voltage configuration registers in the power IC device. Two different register address values can be configured.

3.6.5.2.3 PRM_VC_SMPS_CMD_RA (Voltage Controller SMPS Command Register Address Register)

This register stores the address value of the command configuration register in the power IC device. Two different register address values can be configured.

3.6.5.2.4 PRM_VC_CMD_VAL_0 and PRM_VC_CMD_VAL_1 (Voltage Controller Command and Voltage Value Register 0 and 1)

The voltage controller can store two sets of voltage-level commands for each of the four power states (on, low power, retention, and off) for the power IC. The voltage commands depend on the power IC device used.

3.6.5.2.5 PRM_VC_CH_CONF (Voltage Controller Channel Configuration Register)

This register consists of a set of select bits for the VDD1 and VDD2 channels, the slave address, command register address, voltage register address, and voltage-level command settings for power modes (on/low power, on/retention/off). A pair of bit fields can be configured for each of these parameters. The PRM_VC_CH_CONF register allows the allocation of either of the two bit fields (for each of these parameters) to each voltage channel (VDD1 and VDD2). For example, when PRCM.PRM_VC_CH_CONF[0] SA0 = 0x1, the voltage controller allocates PRCM.PRM_VC_SMPS_SA[22:16] SA1 as the slave address for the VDD1 channel. When PRCM.PRM_VC_CH_CONF[0] SA0 = 0x0, the voltage controller allocates PRCM.PRM_VC_SMPS_SA[6:0] SA0 as the slave address for the VDD1 channel.

3.6.5.2.6 PRM_VC_I2C_CFG (Voltage Controller I^2C Interface Configuration Register)

This register allows the setting of the I^2C interface configuration parameters:

- Master code value when I^2C interface is used in HS mode
- Enable and disable the HS mode
- Enable and disable the repeated start-operation mode
- Enable and disable the HSMASTER mode

3.6.5.2.7 PRM_VC_BYPASS_VAL (Voltage Controller Bypass Command Register)

This register is used to address directly the power IC device through the I^2C interface. It has the following bit fields:

- SLAVEADDR: Slave address value of the I^2C interface of the power IC device (similar to PRM_VC_SMPS_SA)
- REGADDR: Address of the command or voltage value register of the power IC device (similar to PRM_VC_SMPS_VOL_RA or PRM_VC_SMPS_CMD_RA)
- DATA: Data to be written to the command or voltage value register
- VALID: Voltage command transaction enable and acknowledge bit

3.6.5.3 Voltage Processor Registers

Two identical sets of registers allow controlling both voltage processor modules.

The register sets are composed of the following registers:

- PRM_VPn_CONFIG: PRM_VP1_CONFIG and PRM_VP2_CONFIG
- PRM_VPn_VSTEPMIN: PRM_VP1_VSTEPMIN and PRM_VP2_VSTEPMIN
- PRM_VPn_VSTEPMAX: PRM_VP1_VSTEPMAX and PRM_VP2_VSTEPMAX
- PRM_VPn_VLIMITTO: PRM_VP1_VLIMITTO and PRM_VP2_VLIMITTO
- PRM_VPn_VOLTAGE: PRM_VP1_VOLTAGE and PRM_VP2_VOLTAGE
- PRM_VPn_STATUS: PRM_VP1_STATUS and PRM_VP2_STATUS

3.6.5.3.1 PRM_VP_CONFIG (Voltage Processor Configuration Register)

This register allows the configuration of the voltage processor module. It controls the following features of the voltage processor:

- Enable/disable the voltage processor
- Force a voltage update into the power IC device
- Initialize the power IC device initial VDD value into the voltage processor
- Enable/disable the time-out capability of the voltage processor
- Set the power IC initial VDD value
- Set the error to voltage controller gain value
- Set the error to voltage controller error offset

The device has the following voltage processor configuration registers:

- PRM_VP1_CONFIG
- PRM_VP2_CONFIG

3.6.5.3.2 PRM_VP_VSTEPMIN (Voltage Processor Minimum Voltage Step)

This register allows controlling the following features:

- The minimum value of a voltage step between two updates
- The slew rate for negative voltage step (in the number of cycles per step)

The device has the following voltage processor configuration registers:

- PRM_VP1_VSTEPMIN
- PRM_VP2_VSTEPMIN

3.6.5.3.3 PRM_VP_VSTEPMAX (Voltage Processor Maximum Voltage Step)

This register allows setting the following:

- The maximum value of a voltage step between two updates
- The slew rate for positive voltage step (in the number of cycles per step)

The device has the following voltage processor configuration registers:

- PRM_VP1_VSTEPMAX
- PRM_VP1_VSTEPMAX

The voltage processor picks up the voltage step and the waiting time among the minimum and maximum values depending on the VDD returned by the error to the voltage controller.

3.6.5.3.4 PRM_VP_VLIMITTO (Voltage Processor Voltage Limit and Time-Out)

This register allows setting the following:

- The minimum allowed voltage value
- The maximum allowed voltage value
- The time-out value (in the number of clock cycles) to wait for an update

The device has the following voltage processor configuration registers:

- PRM_VP1_VLIMITTO
- PRM_VP2_VLIMITTO

3.6.5.3.5 PRM_VP_VOLTAGE (Voltage Processor Voltage Register)

The voltage register in the voltage processor indicates the current value of the power IC device voltage. This register is updated only when the voltage processor sends the update command to the voltage controller.

The device has the following voltage processor voltage registers:

- PRM_VP1_VOLTAGE
- PRM_VP2_VOLTAGE

3.6.5.3.6 PRM_VP_STATUS (Voltage Processor Status Register)

The status register in the voltage processor indicates whether the voltage processor is in idle mode. This information is useful before trying to reprogram the voltage processor. Unlike other voltage processor status events logged as a source of an interrupt on the MPU, the event logged in this register is not a cause of the interrupt.

The device has the following voltage processor status registers:

- PRM_VP1_STATUS
- PRM_VP2_STATUS

3.6.6 Generic Programming Examples

3.6.6.1 Clock Control

The module clock management is controlled through three programmable steps:

- Enabling or disabling the functional clocks
- Enabling or disabling the interface clocks
- Enabling or disabling the automatic idle mode for the interface clocks

3.6.6.1.1 Enabling and Disabling the Functional Clocks

The flow chart in Figure 3-90 shows how to enable or disable a functional clock.

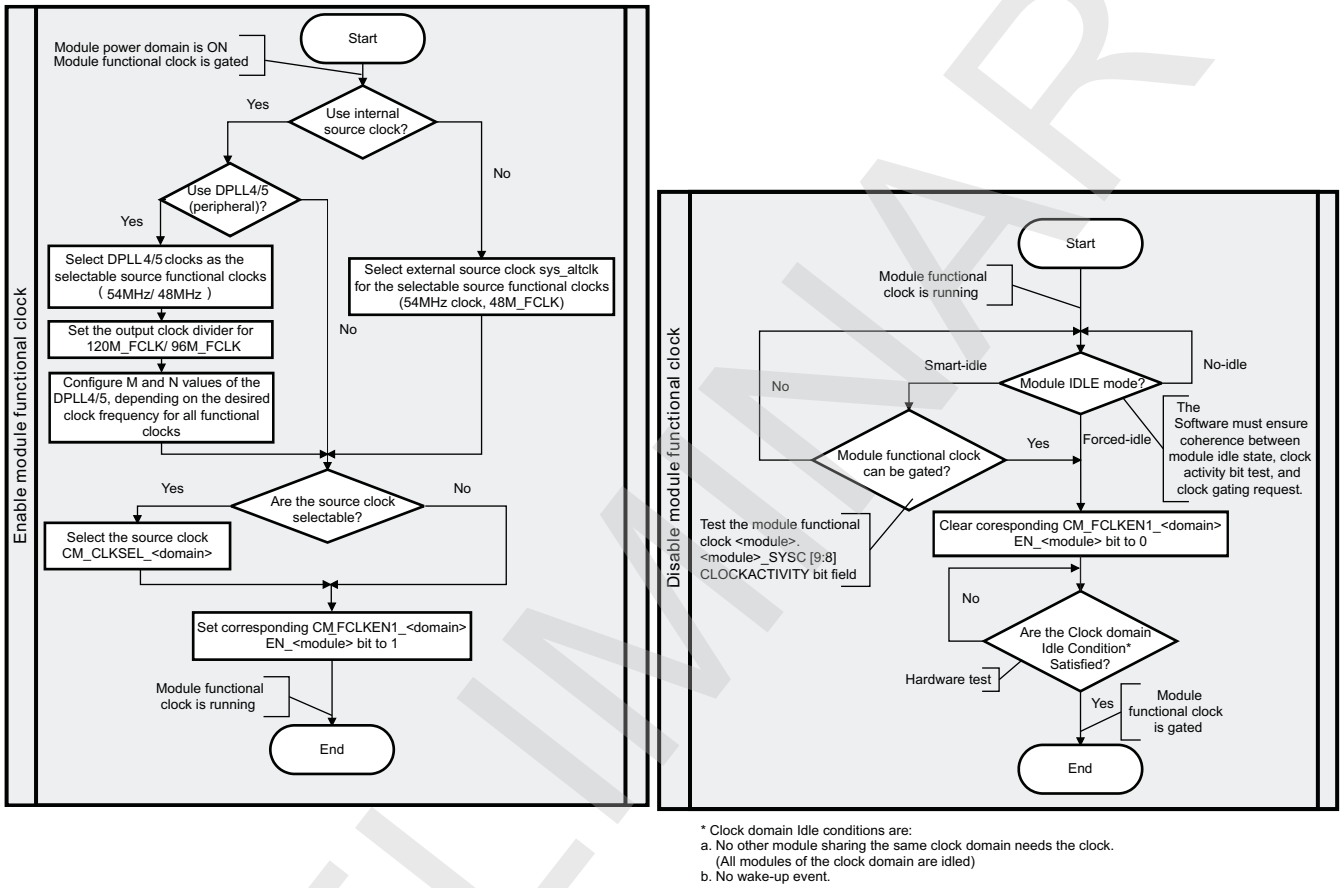
The first step before enabling a functional clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain_name>). It can be either an external source clock or an internal clock; that is, sys_altclk or DPLL4_M3_CLK for the DSS_TV_FCLK functional clock of the DSS.

If the source clock is a DPLL3 or DPLL4 output clock, the DPLL multiplier, divider, and output clock ratios are set in the CM_CLKSELn_PLL register, where n is from 1 to 3. The DPLL operating mode is set in the CM_CLKEN_PLL register.

The functional clock is enabled or disabled by writing the dedicated bit in the CM_FCLKEN_<domain_name> register. This bit has a direct effect on the clock activity:

- The functional clock is turned on if the bit is enabled and the clock is not yet active.
- The functional clock is turned off if the bit is disabled and the clock is not required by any other module.

Figure 3-90. Functional Clock Basic Programming Model



* Clock domain Idle conditions are:
a. No other module sharing the same clock domain needs the clock. (All modules of the clock domain are idled)
b. No wake-up event.

prcm-085

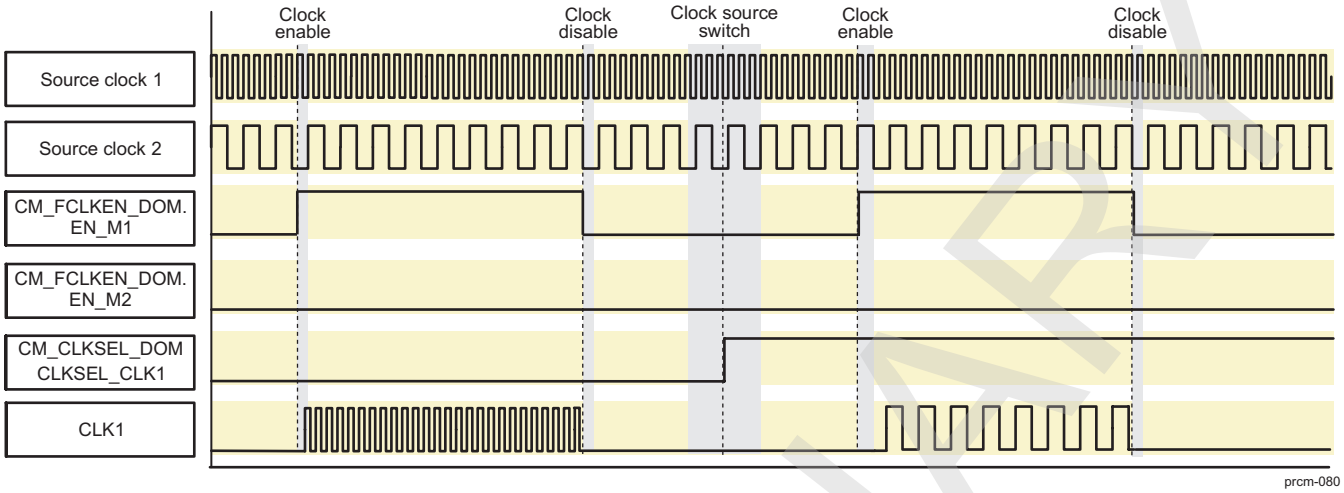
The functional clock must be disabled before switching or scaling its source clock. This means that all the modules using the particular functional clock must not be active during clock switching. To switch a source clock, perform the following sequence:

1. Disable the functional clock by setting the CM_FCLKEN_<power domain>EN_<module> bits to 0.
2. Modify the CM_CLKSEL_<power domain>CLKSEL_<clock> bits to select the new clock source or clock divider.
3. Enable the functional clock by setting the CM_FCLKEN_<power domain>EN_<module> bits to 1.

The timing diagram in Figure 3-91 is a generic example of this sequencing for a functional clock (CLK1). The source clock can be switched between source clock 1 and source clock 2 using the CM_CLKSEL_DOM.CLKSEL_CLK1 bit (source clock 1 is selected when the bit is set to 0; otherwise, source clock 2 is selected). CLK1 can be requested by two modules, M1 and M2. The CM_FCLKEN_DOM.EN_M1 and CM_FCLKEN_DOM.EN_M2 bits control the functional clock enable for the two modules.

NOTE: The activation or deactivation of the clock is implementation-dependent, not one cycle of the source clock, as shown in Figure 3-91.

Figure 3-91. Functional Clock Switching



The following functional clocks require this switching sequence:

- sys_clkout2
- 48M_FCLK (and all gated versions of it)
- 12M_FCLK (and all gated versions of it)
- DSS_TV_CLK
- GPTx_FCLK (with x = 1, 10, and 11)
- GPTx_ALWON_FCLK (with x = 2 up to 9)

3.6.6.1.2 Enabling and Disabling the Interface Clocks

The flow chart in Figure 3-92 shows the enable/disable sequence of the interface clock.

The first step before enabling an interface clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain>). This register allows selection of the interconnect frequency (L3_ICLK, L4_ICLK) from among several divider ratios.

The interface clock is enabled or disabled by writing the dedicated bit in the CM_ICLKEN_<domain> register. This bit has a direct effect on the clock activity:

- The interface clock is turned on if the bit is enabled and the clock is not yet active.
- The interface clock is turned off if the bit is disabled and the clock is not required by any other module.

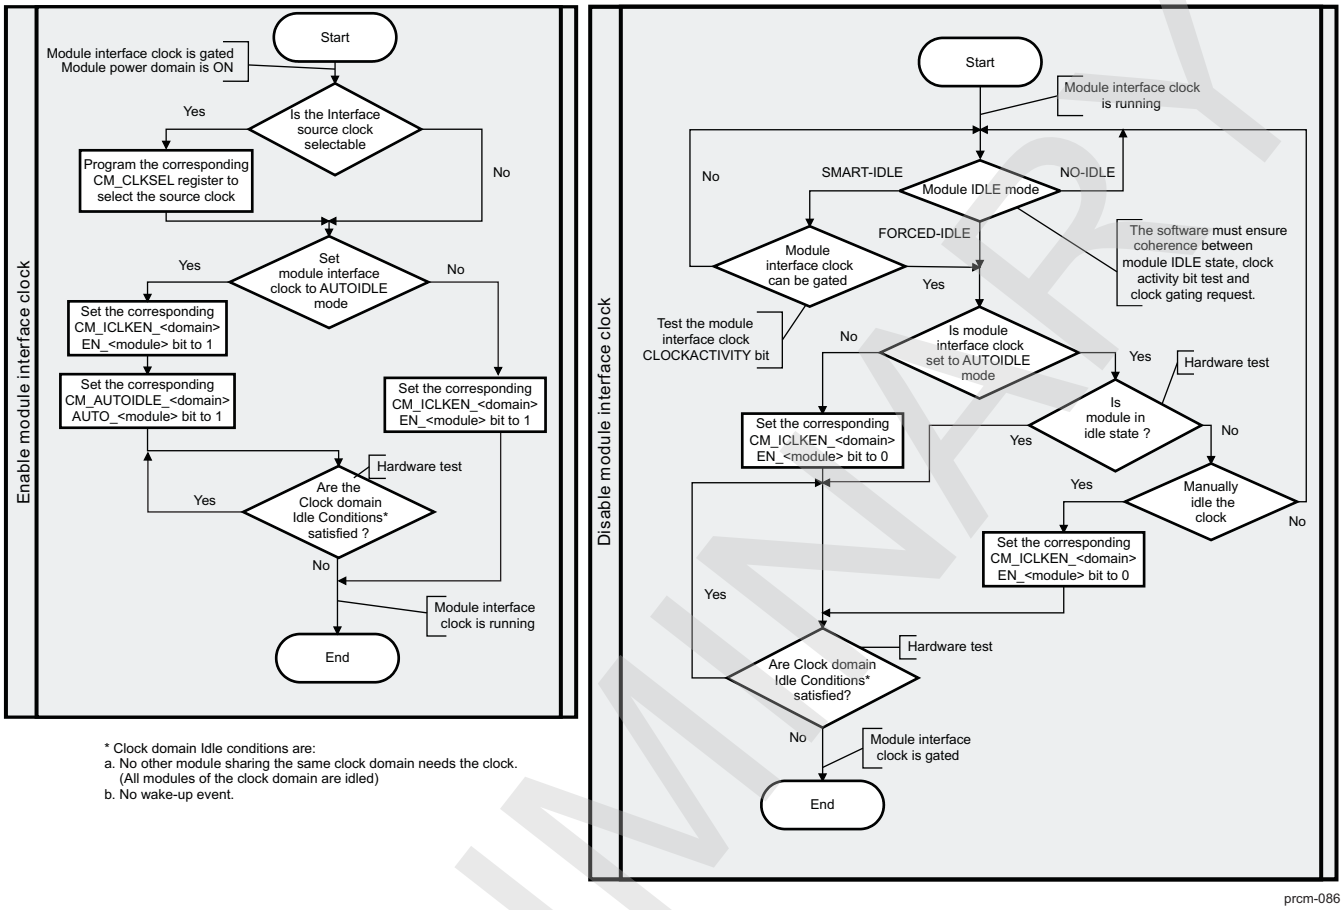
The interface clock can be automatically enabled or disabled by the PRCM module, based on hardware conditions. This automatic clock activity control mode is enabled by writing the corresponding bit in the CM_AUTOIDLE_<domain > register. It takes effect only if the interface clock is enabled (the corresponding bit in the CM_ICLKEN_<domain > is set to 1).

The hardware conditions for automatic gating (deactivation) of the clock are as follows:

- The module activity; that is, the module is inactive.
- The domain activity; that is, all modules in the domain are inactive.

The software can read the idle status register CM_IDLESTAT_<domain> at any time to know whether the module is accessible. A module is inaccessible if its idle status bit is set. Accessing an idle module generates an error (if the interface clock is still running) or a time-out (if the interface clock is cut).

Figure 3-92. Interface Clock Basic Programming Model



The frequency ratio between the CORE_CLK, the L3_ICLK, and the L4_ICLK is configured by setting the corresponding CM_CLKSEL_CORE register bit fields. This configuration must be done before switching DPLL3 to lock mode. In this way, the clock ratio is switched while DPLL3 is operating at system clock frequency, and then only DPLL3 is switched to high-frequency locked mode.

If the configuration of the interface clock needs to be changed, first put DPLL3 in bypass mode, select the new configuration, and then relock DPLL3.

NOTE: When performing frequency scaling, the clock division can be done directly by programming the DPLL output divider. In this case, there is no need to change the configuration of the interface clock.

3.6.6.1.3 Enabling and Disabling the Inactive State

The flow chart in Figure 3-93 shows how to put a domain into inactive state. This state is required before any power transition from on state to retention or off state.

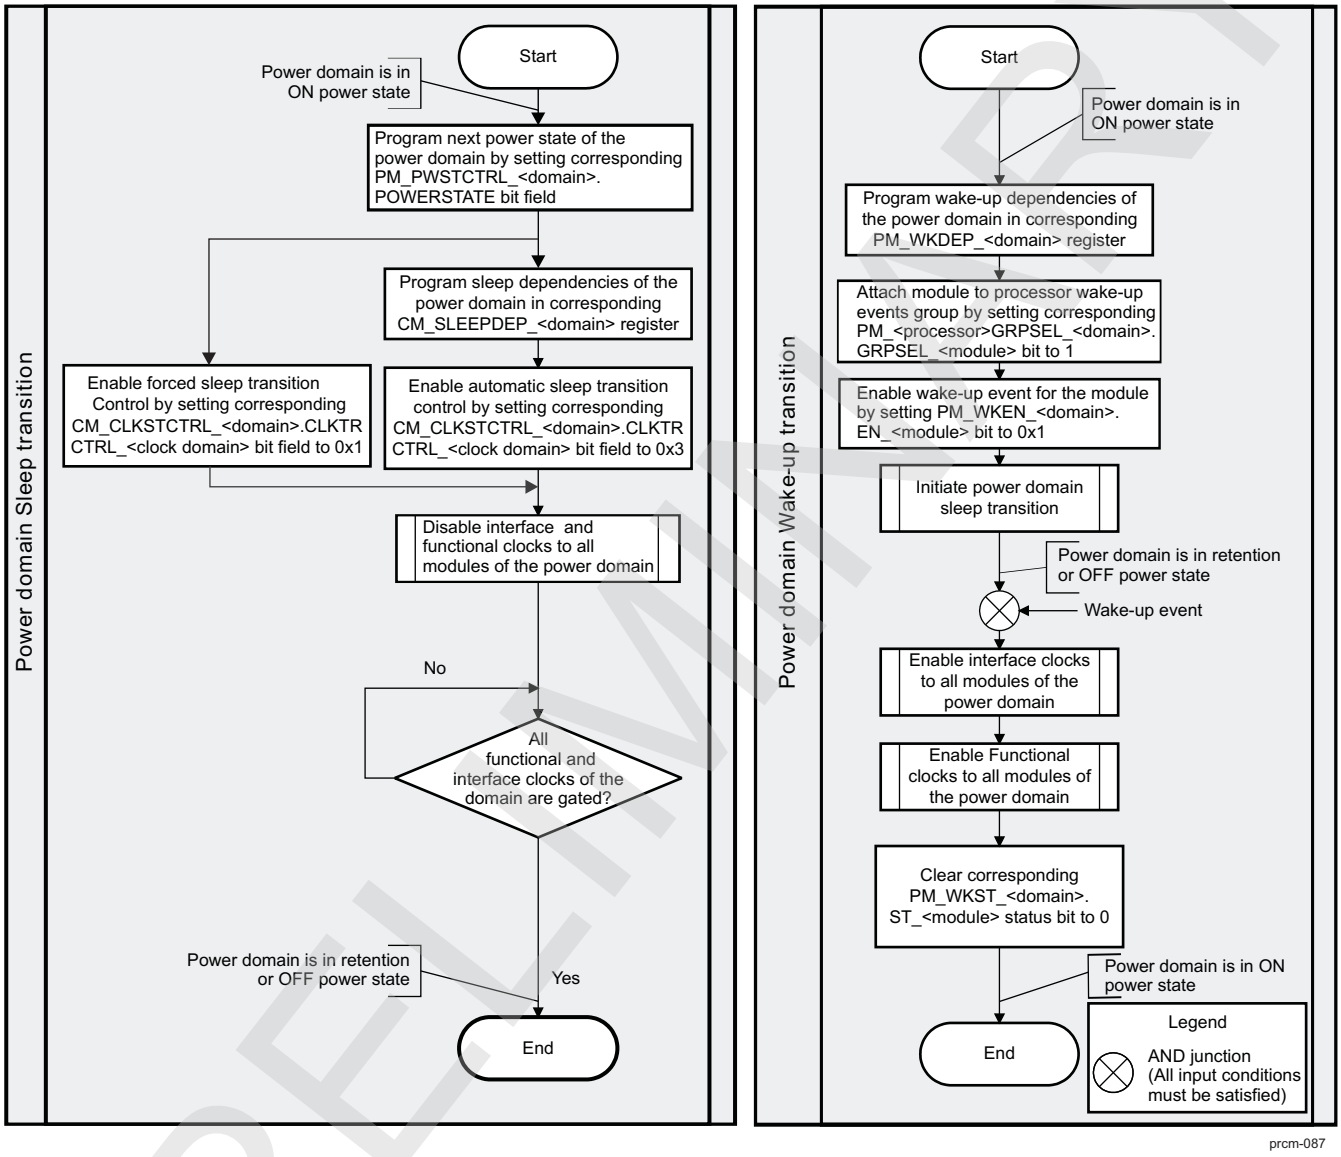
A domain is said to be in inactive state if:

- All the functional and interface clocks of the domain are gated (deactivated).
- All the initiator modules are in standby mode.
- All the dependent domains have reached their mute state. The sleep dependency between the power domains is configured by programming the CM_SLEEPDEP_<domain> register.

The domain transition from active state to inactive state is effective only if the CM_CLKSTCTRL_<domain> register is programmed for hardware-supervised state transition.

The CM_CLKSTST_<domain> register identifies whether a power domain or a clock domain within the power domain is accessible. A domain is inaccessible if its corresponding bit in the CM_CLKSTST_<domain > register is set to 1.

Figure 3-93. Domain Inactive STATE Basic Programming Model



3.6.6.1.4 Processor Clock Control

The flow chart in Figure 3-94 shows the control sequence of the processor clock.

The processor source clock is generated by the dedicated processor DPLL (DPLL1 and DPLL2). After power up, the processor DPLL is in bypass or stop mode. This means the processor clock is either the system clock or is shut off.

The first step is to program the multiplier and divider ratios of the processor DPLL. Those two values are written in the CM_CLKSEL1_PLL_<processor> register.

For frequency scaling, the processor DPLL integrates an additional divider to scale down the synthesized clock. The value of this second divider is written in the CM_CLKSEL2_PLL_<processor> register. This divider can be configured dynamically (while the processor executes instructions), and the DPLL output clock is scaled without any glitches.

The processor DPLL must be locked at a desired frequency, provided the clock frequency is higher than the system clock. It can then be set to low-power bypass mode when the high-frequency clock is not required. The DPLL operating mode (locked or bypassed) is controlled by programming the CM_CLKEN_PLL_<processor> register.

The processor clock can be switched automatically, based on hardware conditions, between the processor DPLL synthesized clock and a bypass clock. This mode is enabled by programming the corresponding mode in the CM_AUTOIDLE_PLL_<processor> register. It takes effect only if the processor DPLL is locked (the CM_CLKEN_PLL_<processor> register is set in lock mode).

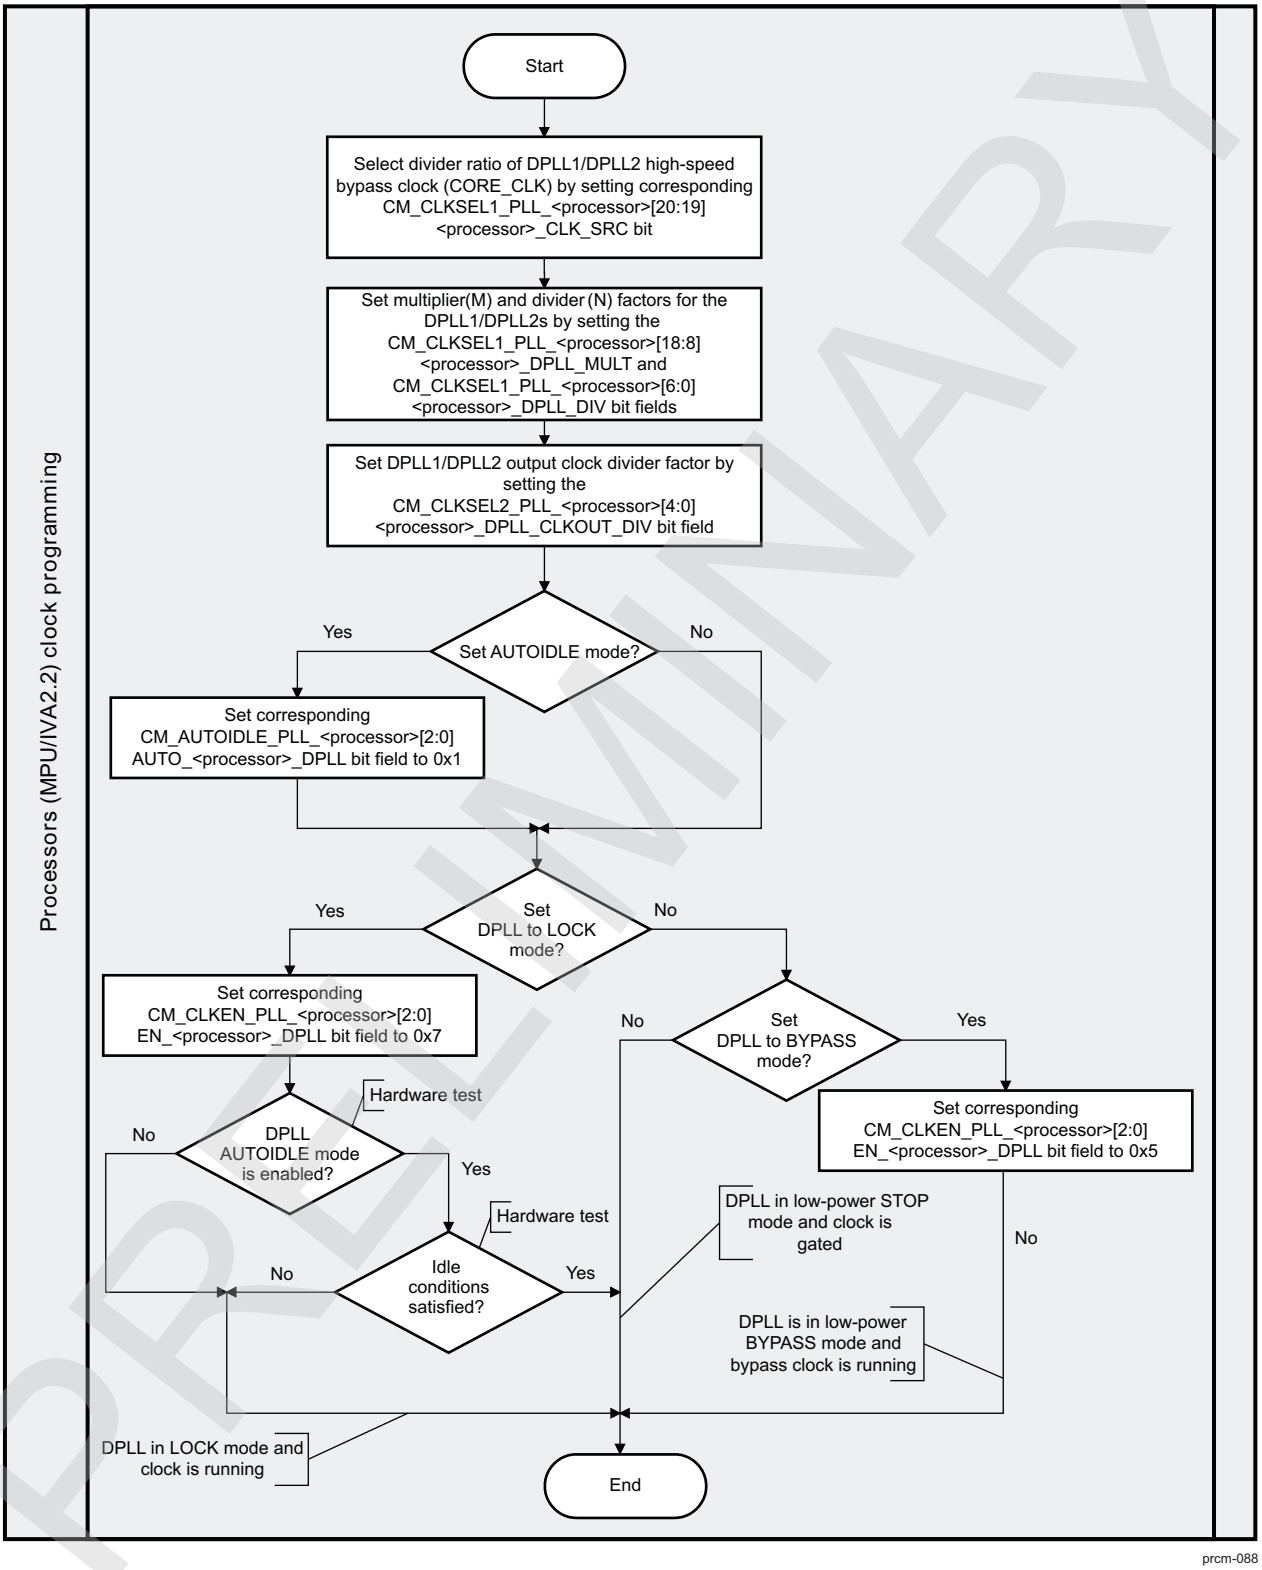
The HS bypass clock for the processor DPLL can be:

- The DPLL3 output clock (CORE_CLK)
- The DPLL3 output clock (CORE_CLK) divided by 2

The HS bypass clock is selected by programming the CM_CLKSEL1_PLL_<processor > register.

The software can read the CM_IDLEST_PLL_<processor > register at any time to determine whether the DPLL is in lock mode (DPLL output is a high-frequency synthesized clock) or bypass mode (DPLL output is not the synthesized clock; the DPLL output is the bypass clock, or the DPLL is in transitioning state).

Figure 3-94. Processor Clock Basic Programming Model



3.6.6.2 Reset Management

The reset sequence is hardware-driven. On power on, once all the reset sources have been released, the PRM holds the entire device under reset long enough to ensure the stabilization of the power IC voltages and the oscillator system clock frequency. This reset delay is programmed in the PRM_RSTTIME register.

The IVA2.2 and the modem domain resets are held active after power up. They are released by writing to the corresponding bits in the RM_RSTCTRL_<domain> register.

A domain reset status register (PRM_RSTST_domain>) identifies the source of the current reset applied to the domain. The software must clear this status bit after reset.

A global reset status register (PRM_RSTST) provides information about the global source of resets. All sources of warm reset are logged separately in this register, and all sources of cold reset are logged in a common status bit.

3.6.6.3 Wake-Up Control

The flow chart in Figure 3-95 shows the control sequence of the module wake-up event.

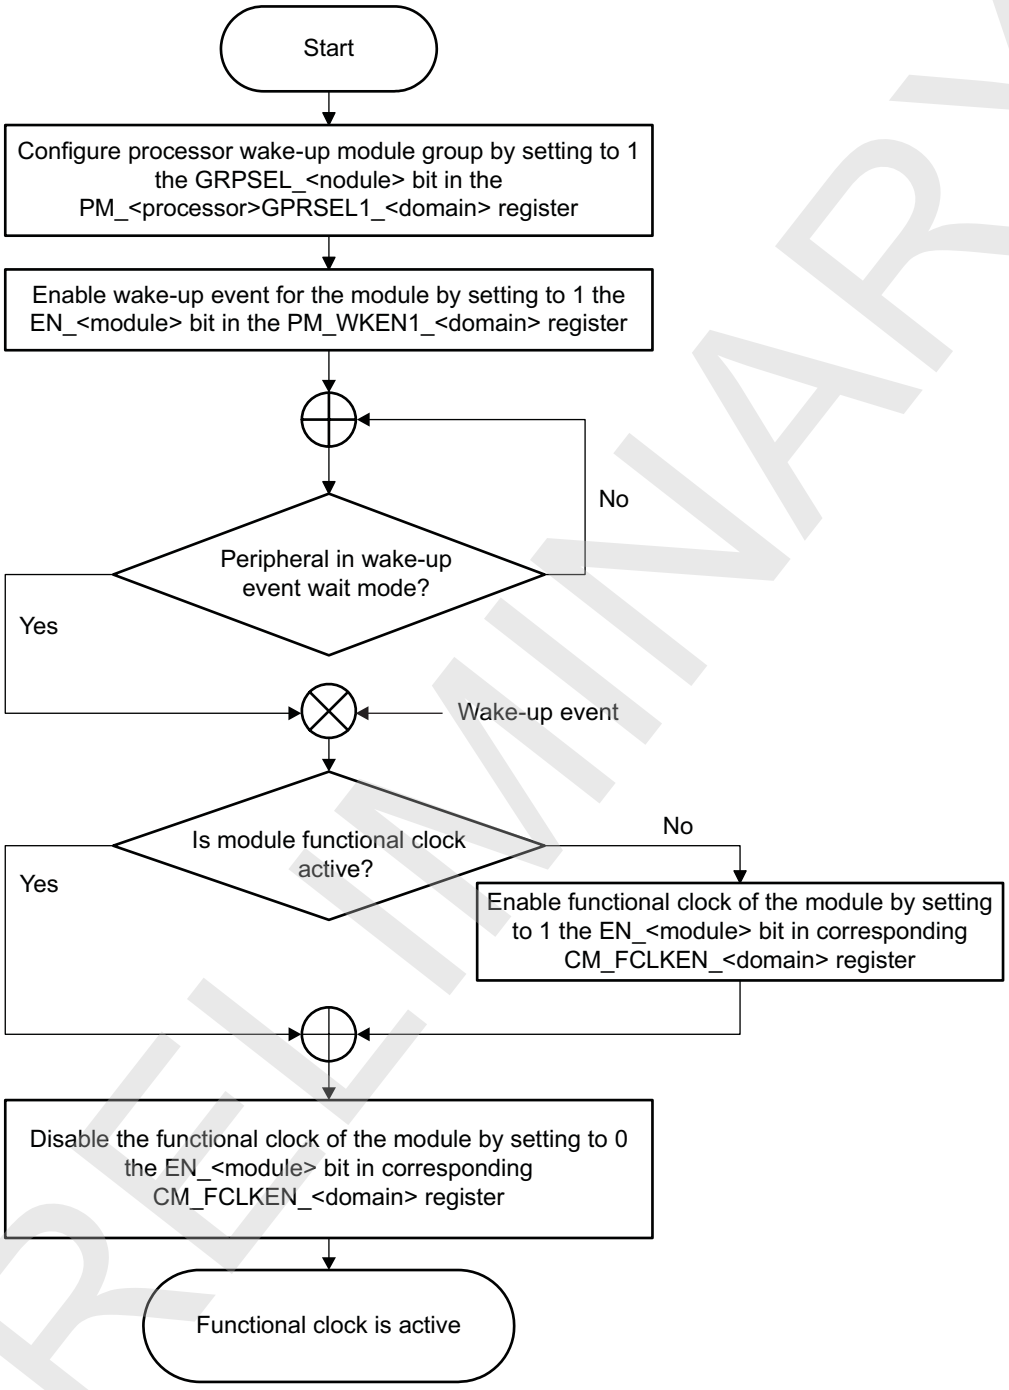
This procedure consists of the following steps:

1. Program the PRCM module to consider the wake-up event.
2. Switch to idle mode and wait for the wake-up event.
3. Wake up on the wake-up event and activate the module functional clock.
4. Acknowledge the wake-up event.

The peripheral that can generate a wake-up event must be attached to a group of wake-up event generating modules for one or both processors by programming the PM_<processor>GRPSEL register. Writing 1 to this register allows the corresponding processor to be wakened on a peripheral wake-up event, assuming that the peripheral wake-up capability has been enabled by programming the register PM_WKEN_<domain>.

After this is configured, the PRCM module initiates a wake-up procedure on receiving the peripheral wake-up event. The peripheral functional clock must be reenabled by programming the CM_FCLKEN_<domain > register, and then the wake-up event can be acknowledged by clearing the PM_WKST_<domain > register.

Figure 3-95. Wake-up Basic Programming Model

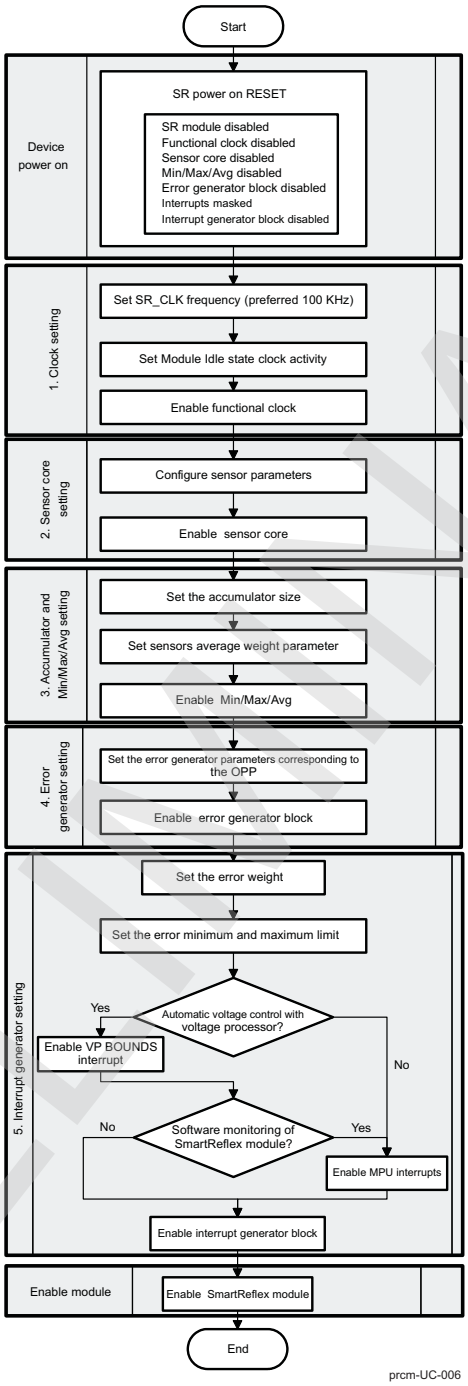


A power domain A can have a functional dependency on a power domain B. Thus, when power domain A wakes up, it may be necessary to wake up power domain B. This wake-up dependency is hardcoded for the CORE power domain, but is programmable for the other power domains through the PM_WKDEP_<domain> register.

3.6.6.4 SmartReflex Module Initialization Basic Programming Model

Figure 3-96 is a flow chart of the SmartReflex initialization.

Figure 3-96. SmartReflex Initialization Flow Chart



After the device power-on reset is complete, the SmartReflex module is disabled and its functional clock is gated.

1. Clock setting

   Setting the clock consists of configuring the internal clock frequency of the SmartReflex module and the state of the functional clock when the module switches to inactive state, and then enabling the functional clock from the PRCM module of the device.

   The internal clock frequency configuration depends on the frequency of SR_ALWON_FCLK and can be calculated from Equation 2. For example, if SR_ALWON_FCLK has a frequency of 38.4 MHz, and the target SR_CLK frequency is 100 kHz, SRCLKLENGTH is set to 192 (0x0C0).

SRn.SRCONFIG[21:12] SRCLKLENGTH		Calculated from Equation 1
PRCM.CM_FCLKEN_WKUP[6] EN_SR1	0x1	SR1 functional clock enable
PRCM.CM_FCLKEN_WKUP[7] EN_SR2	0x1	SR2 functional clock enable

2. Sensor core setting

   Setting the sensor core consists of configuring the sensor core parameters and enabling the sensor core. The sensor core parameters are obtained by reading the CONTROL.CONTROL_FUSE_OPP_4[23:16] and CONTROL.CONTROL_FUSE_OPP_4[31:24] bit fields.

SRn.SRCONFIG[1] SENNENABLE		Configured according to the values read for the SCM register.
SRn.SRCONFIG[4:3] SENPENABLE		See Section 3.5.6.5.4.5, *Parameter Configuration*.
SRn.SRCONFIG[10] SENENABLE	0x1	Enable the sensor module.

3. Accumulator and minimum/maximum/average setting

   The accumulator setting consists of setting the size of the accumulator. The minimum/maximum/average setting consists of setting the average weight parameter for the A and B sensors, and then enabling the minimum/maximum/average block. The accumulator size is calculated using Equation 1.

   For example, if the SR_CLK has a frequency of 100 kHz, and the accumulator time window is 5 ms, ACCUMDATA is set to 500 (0x1F4).

SRn.SRCONFIG[31:22] ACCUMDATA		Calculated from Equation 2
SRn.AVGWEIGHT[1:0] SENNAVGWEIGHT		Provided after silicon characterization
SRn.AVGWEIGHT[3:2] SENPAVGWEIGHT		
SRn.SRCONFIG[8] MINMAXAVGENABLE	0x1	Enable minimum/maximum/average.

4. Error generator setting

   The error generator setting consists of setting the four reference value parameters according the current OPP, and then enabling the error generator.

SRn.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the values read for the current operating voltage level from the SCM register
SRn.NVALUERECIPROCAL[19:16] SENNGAIN		See Section 3.5.6.5.4.5, *Parameter Configuration*.
SRn.NVALUERECIPROCAL[15:8] RNSENP		
SRn.NVALUERECIPROCAL[7:0] RNSENN		
SRn.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

5. Interrupt generator setting

   The interrupt generator setting consists of setting the error weight and the minimum/maximum error limits. Then, depending on operational requirements for hardware and software voltage control, the voltage processor interrupts are configured.

   With software voltage control, the voltage processor interrupt remains disabled and only the MPU interrupts are enabled.

   With automatic hardware voltage control, the voltage processor interrupt is enabled. The MPU interrupts can also be enabled to monitor the SmartReflex module behavior.

   For details about the interrupts, see Table 3-85.

SRn.ERRCONFIG[18:16] ERRWEIGHT		Provided after silicon characterization
SRn.ERRCONFIG[15:8] ERRMAXLIMIT		
SRn.ERRCONFIG[7:0] ERRMINLIMIT		
SRn.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the VP bounds interrupt.
SRn.IRQENABLE_SET[3] MCUACCUMINTENASET	0x1	Enable the MCU accumulator interrupt.
SRn.IRQENABLE_SET[2] MCUVALIDINTENASET	0x1	Enable the MCU valid interrupt.

SRn.IRQENABLE_SET[1] MCUBOUNDSINTSTATENA	0x1	Enable the MCU bounds interrupt.

6. Enable the module

   In the final phase of configuration, the SmartReflex module is enabled. When the module is enabled, the sensors generate values and the error generator is active. The module can generate the interrupt when the enabled interrupt conditions occur.

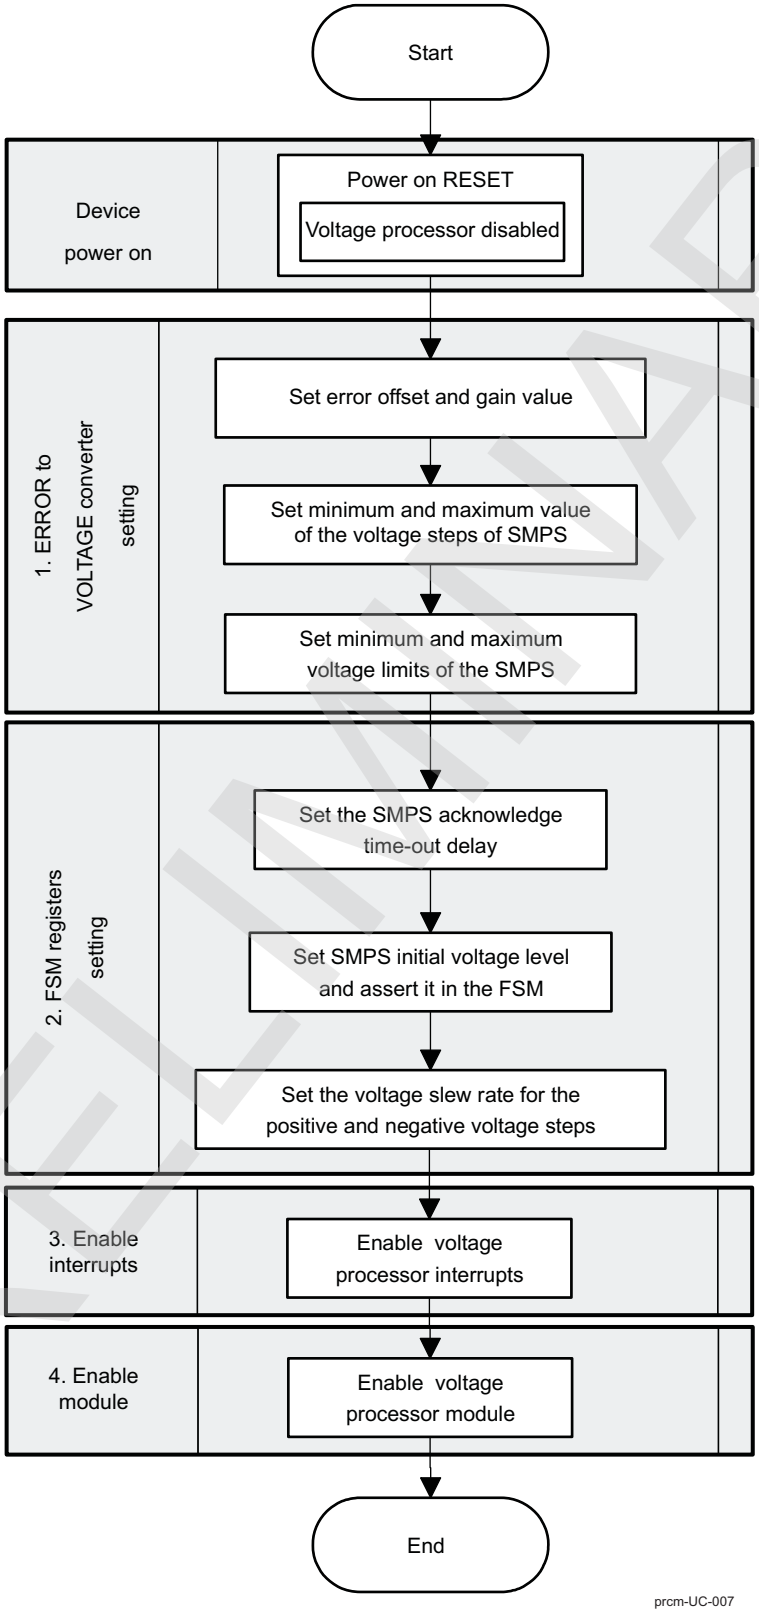
SRn.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex module.

NOTE: Each time the device configuration is changed (for instance, the OPP is switched) after this initial configuration phase completes, the module must be disabled.

3.6.6.5 Voltage Processor Initialization Basic Programming Model

Figure 3-97 is a flow chart of the voltage processor initialization.

Figure 3-97. Voltage Processor Initialization Flow Chart



1. Error-to-voltage converter setting
   The error-to-voltage converter setting consists of configuring the error offset, error gain, minimum and

maximum step size, and the minimum and maximum voltage limits, depending on the characteristics of the SMPS. The default voltage level of the SMPS, after boot up, must also be configured.

NOTE: For the characteristics of the SMPS, see the power IC device performance addendum.

PRCM.PRM_VPn_CONFIG[31:24] ERROROFFSET		Depend on the characteristics of the SMPS.
PRCM.PRM_VPn_CONFIG[13:16] ERRORGAIN		
PRCM.PRM_VPn_VSTEPMIN[7:0] VSTEPMIN		
PRCM.PRM_VPn_VSTEPMAX[7:0] VSTEPMAX		

2. FSM register setting

   The FSM register settings consist of setting the time-out delay for the acknowledge return from SMPS, the initial voltage level of the SMPS and asserting it in the FSM, and setting the slew rate for the positive and negative voltage steps of the SMPS.

   The time-out delay ensures that the voltage processor is not blocked if there is no command acknowledge by the SMPS.

   NOTE:

   - When an initial voltage is configured and asserted to the FSM, it is added to the SMPS voltage register in the voltage processor, but it is not sent as a command to the SMPS.
   - The slew rates programmed into the voltage processor depend on the characteristics of the SMPS.

PRCM.PRM_VPn_VLIMITTO[15:0] TIMEOUT		Maximum amount of time to wait for the command acknowledge from the SMPS
PRCM.PRM_VPn_CONFIG[15:8] INITVOLTAGE		Initial voltage level of the SMPS
PRCM.PRM_VPn_CONFIG[2] INITVDD	0x1	Assert the initial voltage into the voltage processor FSM.
PRCM.PRM_VPn_VSTEPMIN[23:8] SMPSWAITTIMEMIN		Slew rate of the negative voltage step of the SMPS
PRCM.PRM_VPn_VSTEPMAX[23:8] SMPSWAITTIMEMAX		Slew rate of the positive voltage step of the SMPS

3. Enable interrupts

   The interrupt generator setting consists of setting the error weight and the minimum/maximum error limits. Then depending on operational requirements for hardware or software voltage control, the voltage processor interrupts are configured.

   With software voltage control, the voltage processor interrupt remains disabled and only the MPU interrupts are enabled.

   With automatic hardware voltage control, the voltage processor interrupt is enabled. The MPU interrupts can also be enabled to monitor the SmartReflex module behavior.

   For details about the interrupts, see Table 3-85.

PRCM.PRM_IRQENABLE_MPU[21] VP2_TRANXDONE_EN	-	0x0: Mask the VP2 transaction-done interrupt. (Default)
		0x1: Unmask the VP2 transaction-done interrupt.
PRCM.PRM_IRQENABLE_MPU[15] VP1_TRANXDONE_EN	-	0x0: Mask the VP1 transaction-done interrupt. (Default)
		0x1: Unmask the VP1 transaction-done interrupt.
PRCM.PRM_IRQENABLE_MPU[20] VP2_EQVALUE_EN	-	0x0: Mask the VP2 equal-value interrupt. (Default)
		0x1: Unmask the VP2 equal-value interrupt.
PRCM.PRM_IRQENABLE_MPU[14] VP1_ EQVALUE_EN	-	0x0: Mask the VP1 equal-value interrupt. (Default)
		0x1: Unmask the VP1 equal-value interrupt.
PRCM.PRM_IRQENABLE_MPU[19] VP2_NOSMPSACK_EN	-	0x0: Mask the VP2 no-SMPS acknowledge. (Default)

		0x1: Unmask the VP2 no-SMPS acknowledge.
PRCM.PRM_IRQENABLE_MPU[13] VP1_ NOSMPSACK_EN	-	0x0: Mask the VP1 no-SMPS acknowledge interrupt. (Default)
		0x1: Unmask the VP1 no-SMPS acknowledge interrupt.
PRCM.PRM_IRQENABLE_MPU[18] VP2_MAXVDD_EN	-	0x0: Mask the VP2 maximum-VDD interrupt. (Default)
		0x1: Unmask the VP2 maximum-VDD interrupt.
PRCM.PRM_IRQENABLE_MPU[12] VP1_ MAXVDD_EN	-	0x0: Mask the VP1 maximum-VDD interrupt. (Default)
		0x1: Unmask the VP1 maximum-VDD interrupt.
PRCM.PRM_IRQENABLE_MPU[17] VP2_MINVDD_EN	-	0x0: Mask the VP2 minimum-VDD interrupt. (Default)
		0x1: Unmask the VP2 minimum-VDD interrupt.
PRCM.PRM_IRQENABLE_MPU[11] VP1_ MINVDD_EN	-	0x0: Mask the VP1 minimum-VDD interrupt. (Default)
		0x1: Unmask the VP1 minimum-VDD interrupt.
PRCM.PRM_IRQENABLE_MPU[16] VP2_OPPCHANGEDONE_EN	-	0x0: Mask the VP2 OPP change-done interrupt. (Default)
		0x1: Unmask the VP2 OPP change-done interrupt.
PRCM.PRM_IRQENABLE_MPU[10] VP1_ OPPCHANGEDONE_EN	-	0x0: Mask the VP1 OPP change-done interrupt. (Default)
		0x1: Unmask the VP1 OPP change-done interrupt.

4. Enable the module

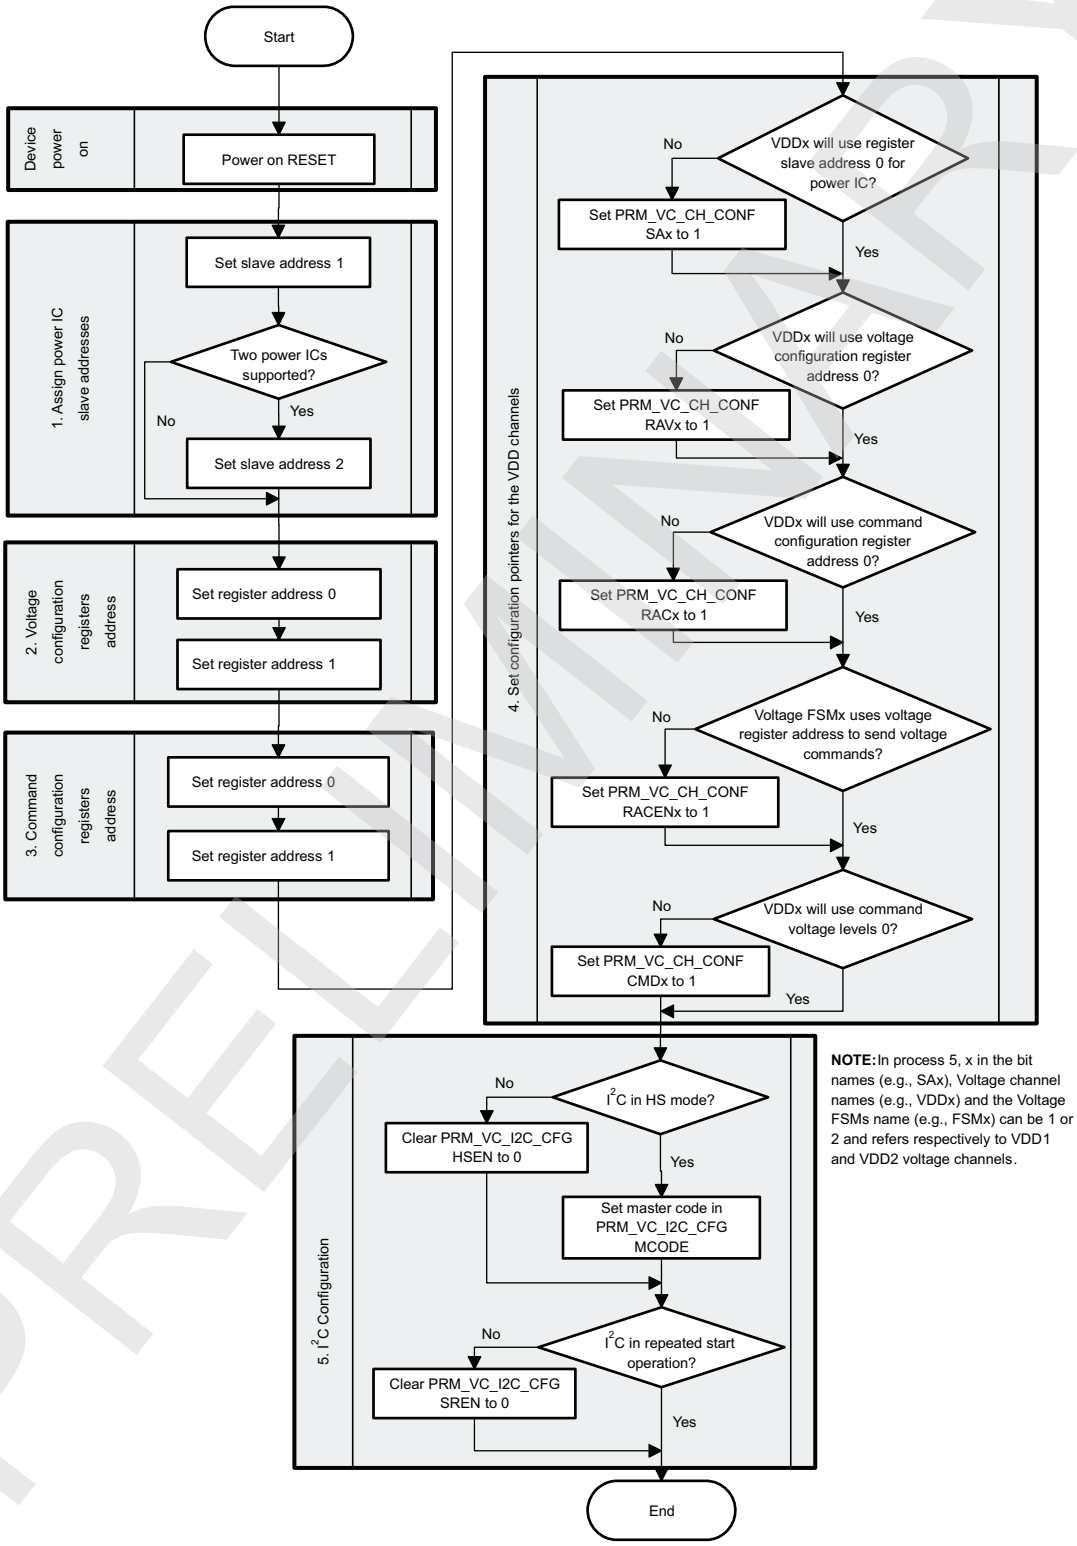
   In the final phase of configuration, the voltage-processor module is enabled. Once the module is enabled, any interrupt from the SmartReflex module triggers the module FSM. The voltage processor reads the frequency error and converts it to the corresponding voltage command for the SMPS. It then waits for a command acknowledge from the SMPS before clearing the SmartReflex interrupt.

PRCM.PRM_VPn_CONFIG[0] VPENABLE	0x1	Enable the voltage processor module.

3.6.6.6 Voltage Controller Initialization Basic Programming Model

Figure 3-98 is the flow chart for voltage controller initialization.

Figure 3-98. Voltage Controller Initialization Flow Chart



1. Assign power IC slave addresses.

To support the I²C communication with external power ICs, the slave address of the power ICs must be configured in the voltage controller registers. The voltage controller can support two slave addresses to control VDD1 and VDD2 independently, from two different power ICs. At least one valid slave address is required to communicate with a power IC.

NOTE: The slave address for the following depends on the configured slave address of the power IC:

- PRCM.PRM_VC_SMPS_SA[6:0] SA0
- PRCM.PRM_VC_SMPS_SA[22:16] SA1

2. Set voltage configuration register addresses.

   The addresses of the voltage configuration registers of the power ICs are set in the corresponding bit fields. The voltage controller can support addresses of two different voltage configuration registers (belonging to same or different power ICs).

PRCM.PRM_VC_SMPS_VOL_RA[7:0] VOLRA0		Depend on the characteristics of the connected power ICs.
PRCM.PRM_VC_SMPS_VOL_RA[23:16] VOLRA1		

3. Set command configuration register addresses.

   The addresses of the command configuration registers of the power ICs are set in the corresponding bit fields. The voltage controller can support addresses of two different command configuration registers (belonging to same or different power ICs).

PRCM.PRM_VC_SMPS_CMD_RA[7:0] CMDRA0		Depend on the characteristics of the connected power ICs.
PRCM.PRM_VC_SMPS_CMD_RA[23:16] CMDRA1		

4. Set configuration pointers for the VDD channels.

   The configuration pointers allow the selection of one of four configurations for each voltage channel (VDD1 and VDD2):

   - Two slave I²C interfaces (slave address)
   - Two voltage configuration registers
   - Two command configuration registers
   - Two power-mode voltage levels

PRCM.PRM_VC_CH_CONF[16] SA1		Slave address pointer (SA1 for VDD2, and SA0 for VDD1)
PRCM.PRM_VC_CH_CONF[0] SA0		
PRCM.PRM_VC_CH_CONF[17] RAV1		Voltage configuration register address pointer (RAV1 for VDD2, and RAV0 for VDD1)
PRCM.PRM_VC_CH_CONF[1] RAV0		
PRCM.PRM_VC_CH_CONF[18] RAC1		Command configuration register address pointer (RAC1 for VDD2, and RAC0 for VDD1)
PRCM.PRM_VC_CH_CONF[2] RAC0		
PRCM.PRM_VC_CH_CONF[19] RACEN1		Select voltage or command configuration register for FSM commands (RACEN1 for VDD2, and RACEN0 for VDD1)
PRCM.PRM_VC_CH_CONF[3] RACEN0		
PRCM.PRM_VC_CH_CONF[20] CMD1		Command voltage level selection pointer (CMD1 for VDD2, and CMD0 for VDD1)
PRCM.PRM_VC_CH_CONF[4] CMD0		

5. Configure I²C.

   At power-on reset, the I2C4 is in HS mode. In HS mode, a master code value must be configured for the preamble I²C HS transmission. If the external power ICs do not support I²C HS mode, the interface can be switched to fast/standard (F/S) mode. By default, a repeated-start operation for communication is enabled. If necessary, it can be disabled.

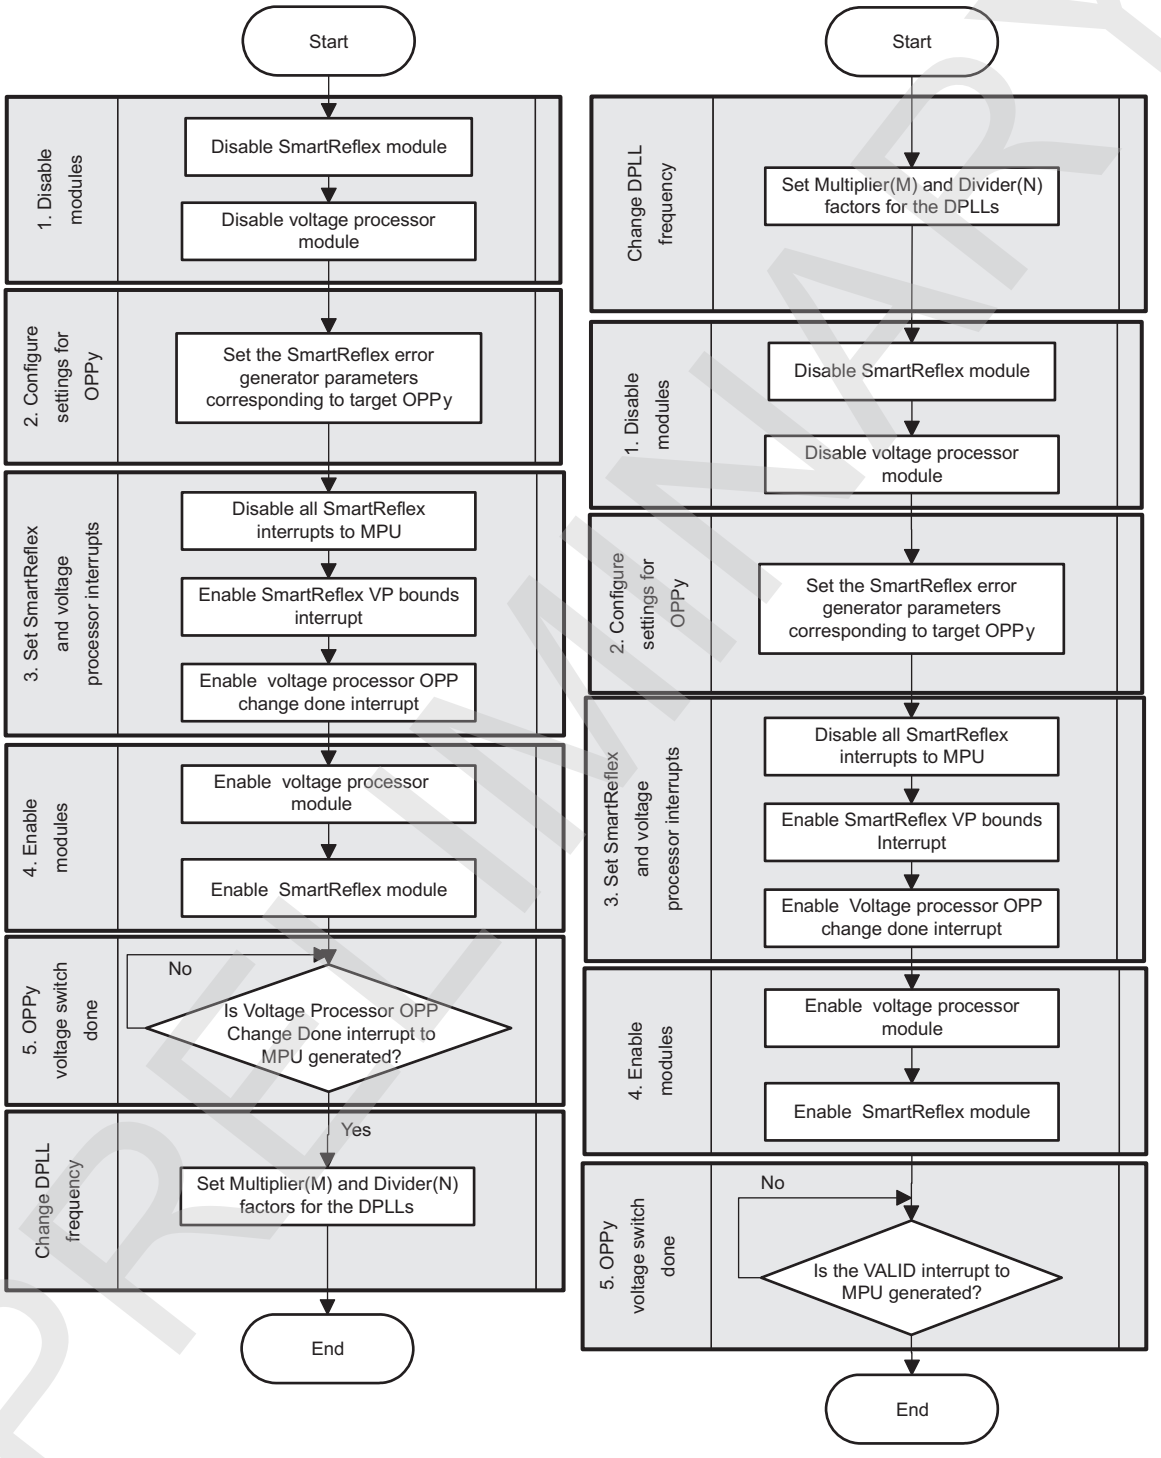
   For more information, see Chapter 17, *I²C*.

PRCM.PRM_VC_I2C_CFG[2:0] MCODE		Master code for I²C HS preamble
PRCM.PRM_VC_I2C_CFG[3] HSEN	0x0	Switch to F/S mode.
PRCM.PRM_VC_I2C_CFG[4] SREN	0x0	Disable repeated start operation.

3.6.6.7 Changing OPP Using the SmartReflex Module

Figure 3-99 is a flow chart of the OPP change.

Figure 3-99. SmartReflex - OPP Change Flow Chart



(a) Switching from VDDx(Vx,Fx) to VDDy(Vy,Fy) where Fy > Fx

(b) Switching from VDDx(Vx,Fx) to VDDy(Vy,Fy) where Fx > Fy

prcm-uc-009

When switching from OPPx to OPPy so the clock frequency at OPPx is higher than the clock frequency at OPPy, the DPLL is first switched to the lower frequency of OPPy and only voltage scaling is initiated (see Figure 3-99a). However, if the clock frequency of OPPx is less than the frequency of OPPy, voltage scaling is initiated before the frequency scaling (see Figure 3-99b).

OPP voltage switching complete is detected by the OPPCHANGEDONE interrupt from the voltage processor to the MPU. For this, the corresponding MPU interrupt must be unmasked.

NOTE: In the following steps, VPn refers to VP1 if VDD1 OPP is changed, and to VP2 if VDD2 OPP is changed.

1. Disable the modules.

   To configure the parameters of the SmartReflex module, both the SmartReflex and voltage processor modules are disabled. This ensures that no voltage command is passed to the SMPS while the OPP change is being configured.

SRn.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex module.
PRCM.PRM_VPn_CONFIG[0] VPENABLE	0x0	Disable the voltage processor module.

2. Configure settings for OPPy.

   Setting the error generator consists of setting its parameters according to the target OPP, and then enabling the error-generator block. These values are configured according to the target operating performance point of the device.

SRn.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the current OPP values read for the SCM register See Section 3.5.6.5.4.5, *Parameter Configuration*.
SRn.NVALUERECIPROCAL[19:16] SENNGAIN		
SRn.NVALUERECIPROCAL[15:8] RNSENP		
SRn.NVALUERECIPROCAL[7:0] RNSENN		
SRn.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

3. Set SmartReflex and voltage processor interrupts.

   To automatically adjust the voltage from OPPx level to OPPy level, the voltage processor interrupt from the SmartReflex module to the voltage processor module must be is unmasked. Similarly, to detect completion of the switch to OPPy, the OPP change-done interrupt from the voltage processor to the MPU must be unmasked.

   This is especially important when switching to a higher-frequency operating point, because the voltage must be stable before the frequency is switched.

   The remaining SmartReflex and voltage processor interrupts can be masked.

   SmartReflex interrupt setting:

SRn.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the VP bounds interrupt.

   Voltage processor interrupt setting:

PRCM.PRM_IRQENABLE_MPU VPn_OPPCHANGEDONE_EN	0x1	Enable the VPn OPP change-done interrupt.

NOTE: After reset, all interrupts are masked.

4. Enable the modules.

   The voltage processor is enabled first, and then the SmartReflex module is enabled. The SmartReflex module counters start counting the pulses, and the error-generator logic is active. The module generates the error to the voltage processor module to send the voltage command to SMPS. The voltage is thus adjusted according to OPPy.

PRCM.PRM_VPn_CONFIG[0] VPENABLE	0x1	Enable the voltage processor module.
SRn.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex module.

5. OPPy voltage switch is done.

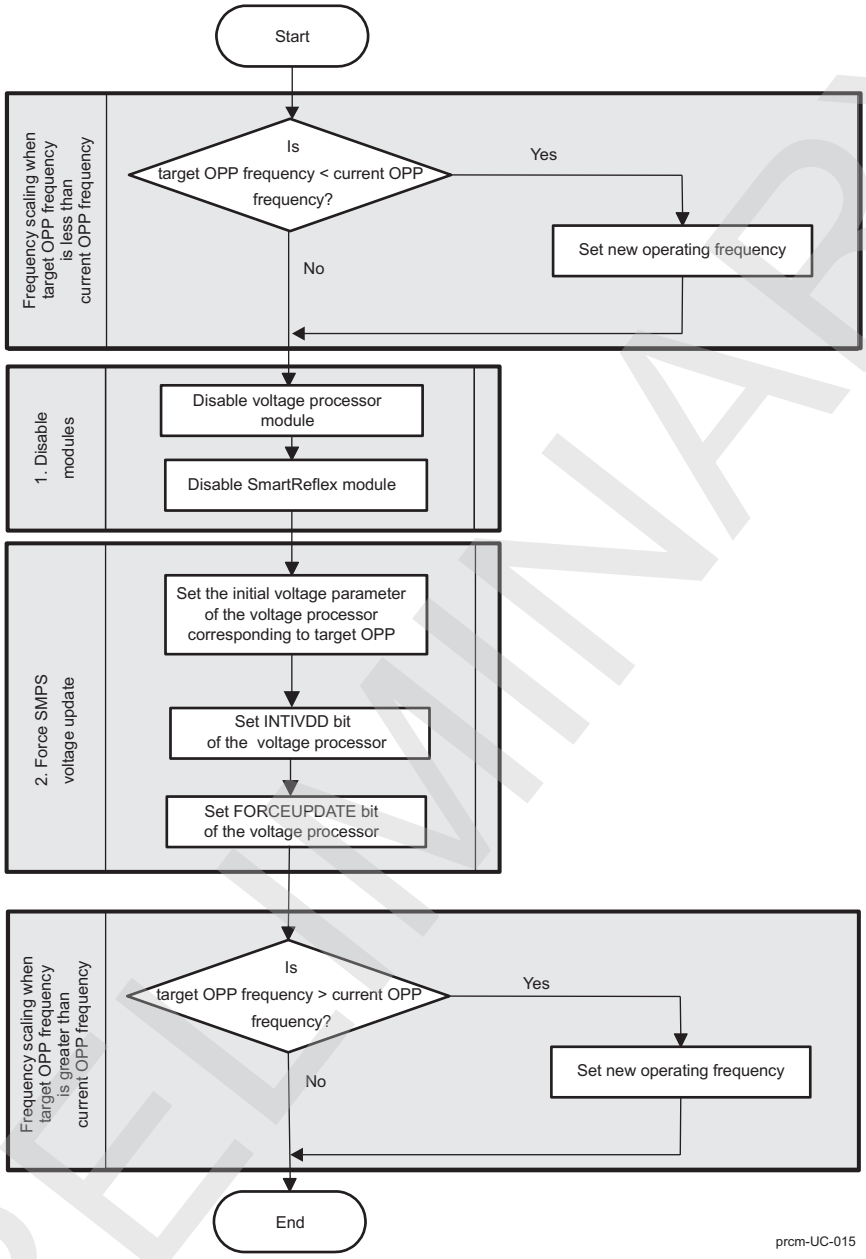
   The voltage processor sends an interrupt to the MPU when the interrupt condition is satisfied (the voltage change from OPPx to OPPy is complete). The interrupt status bit can be read to validate the interrupt, and then cleared by writing 0x1 to it.

PRCM.PRM_IRQSTATUS_MPU VPn_ OPPCHANGEDONE_ST	Read	On read, if this bit is 0x1, the OPP change is complete.
PRCM.PRM_IRQSTATUS_MPU VPn_ OPPCHANGEDONE_ST	0x1	Writing 0x1 clears the interrupt status bit.

3.6.6.8 Changing OPP Using Only the Voltage Processor Module

The device OPP change for the VDD1 or VDD2 voltage domains can also be handled through an alternate method of using only the voltage processor module. In this case, the SmartReflex module is disabled and the voltage processor is configured to initiate the OPP transition. Figure 3-100 is the flow chart of the OPP change.

Figure 3-100. Voltage Processor - OPP Change Flow Chart



When switching from the current OPP to a target OPP, if the clock frequency of the target OPP is less than that of current OPP, the DPLL is first switched to the lower frequency of target OPP, and only then the voltage scaling is initiated. However, if the clock frequency of the target OPP is greater than that of current OPP, voltage scaling is initiated before frequency scaling (see Figure 3-100).

OPP voltage-switching-complete is detected by the OPPCHANGEDONE interrupt from the voltage processor to the MPU. For this, the corresponding MPU interrupt must be unmasked.

NOTE: In the following steps, VPn refers to VP1 if VDD1 OPP is changed, and to VP2 if VDD2 OPP is changed.

1. Disable the modules.

To configure the parameters of the voltage processor module, both the SmartReflex and the voltage processor modules are disabled. This ensures that no voltage command is passed to the SMPS while the OPP change is being configured.

PRCM.PRM_VPn_CONFIG[0] VPENABLE	0x0	Disable the voltage processor module.
SRn.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex module.

2. Force SMPS voltage update.

   The voltage processor INITVDD bit is set so that the initial voltage in the voltage processor module is set according to the target OPP (OPPy). Before asserting the force update command, the voltage processor must be in idle mode. The SMPS is force-updated to switch from OPPx to OPPy by asserting the FORCEUPDATE bit of the voltage processor.

NOTE: The SmartReflex and voltage processor interrupts are masked.

PRCM.PRM_VPn_CONFIG[0] INITVOLTAGE		Configured according to the target OPP voltage value.
PRCM.PRM_VPn_CONFIG[15:8] INITVDD	0x1	Triggers a write of the value in the INITVOLTAGE bit field in the voltage processor
PRCM. PRM_VPn_CONFIG[1] FORCEUPDATE	0x1	Force update of the SMPS.

NOTE: To support OPP50, the DPLL2 and DPLL1 bypass clocks must be set properly. The DPLL1 bypass clock must always be set to CORE_CLK/2. The DPLL2 bypass clock must always be set to CORE_CLK/2. For more information, see Section 3.5.3.8.2, *Interface and Peripheral Functional Clock Configurations*

3.6.6.9 Event Generator Programming Examples

The event generator feature allows the MPU power domain to be switched between on and off (or placed in idled mode). This is intended to implement an efficient activity modulation of the MPU power state with minimum software support.

When the event generator is activated, the PRCM module ensures that the CORE power domain always follows the MPU power domain activity.

The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers of the event generator counter allow the configuration of the on and off durations (the number of system clock cycles) for the MPU power domain. The PRCM.PM_EVGENCTRL_MPU register allows the enabling/disabling of the event generator feature and control of the way on and off values are loaded in the counter.

There are three ways to load the counter with the next counting value:

- Load on update of the corresponding PRCM.PM_EVGENONTIM_MPU or PRCM.PM_EVGENOFFTIM_MPU register.
- Load the on-time value when the MPU power domain wakes up, and the off-time value when the MPU power domain starts the sleep transition (the MPU executes the WFI instruction).
- Automatically load the on-time value when the off-time value expires, and automatically load the off-time value when the on-time value expires.

When the counter times out at the end of the on/off time, it triggers the interrupt/wake-up transition, respectively. The software can use the on-time interrupt to trigger the WFI processor instruction to idle the processor clock. Similarly, the wake-up event at the end of the off time restarts the processor clock and interrupts the processor. To enable the corresponding interrupts, the MPU interrupts mask must be set in the PRCM.PRM_IRQENABLE_MPU register.

3.7 PRCM Use Cases and Tips

3.7.1 DVFS Using Device SmartReflex With TWL5030 Power IC

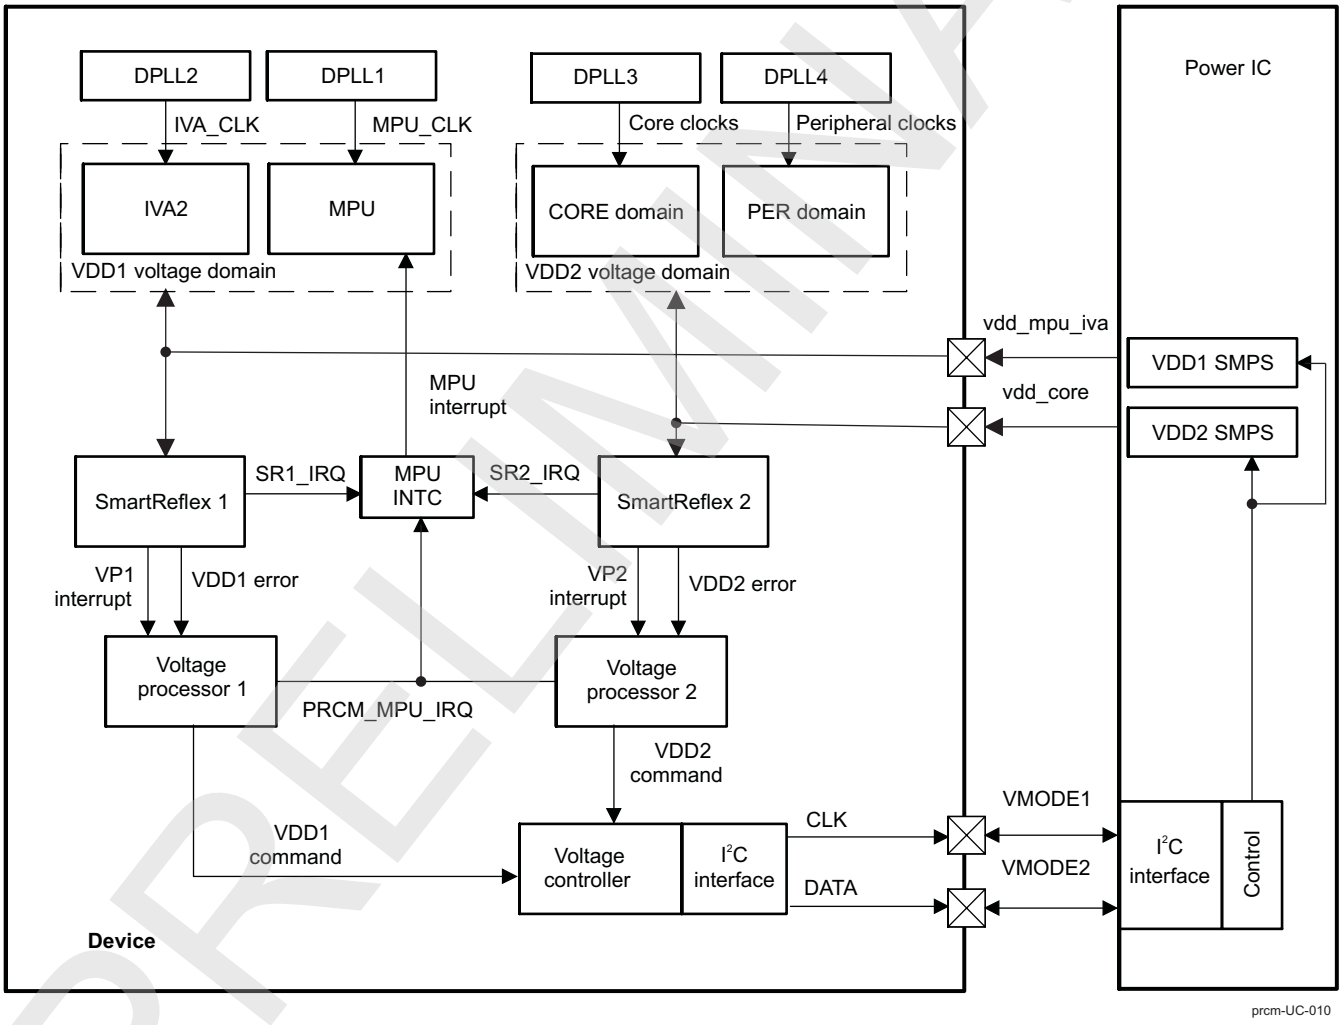
This use case describes SmartReflex-controlled DVFS in the device connected to the TWL5030 power IC. It describes the initial configuration sequence for the device modules and the TWL5030 modules to support DVFS. It also describes the DVFS case when changing from one OPP to another.

The DVFS power-management technique consists of running a module at the lowest operating point (frequency, voltage) that strictly meets the performance requirement at a given time.

In the device, DVFS consists of dynamically switching the voltages and operating frequencies of the device subsections/modules to ensure that power consumption is minimized.

Figure 3-101 is an overview of DVFS management in the device/TWL5030.

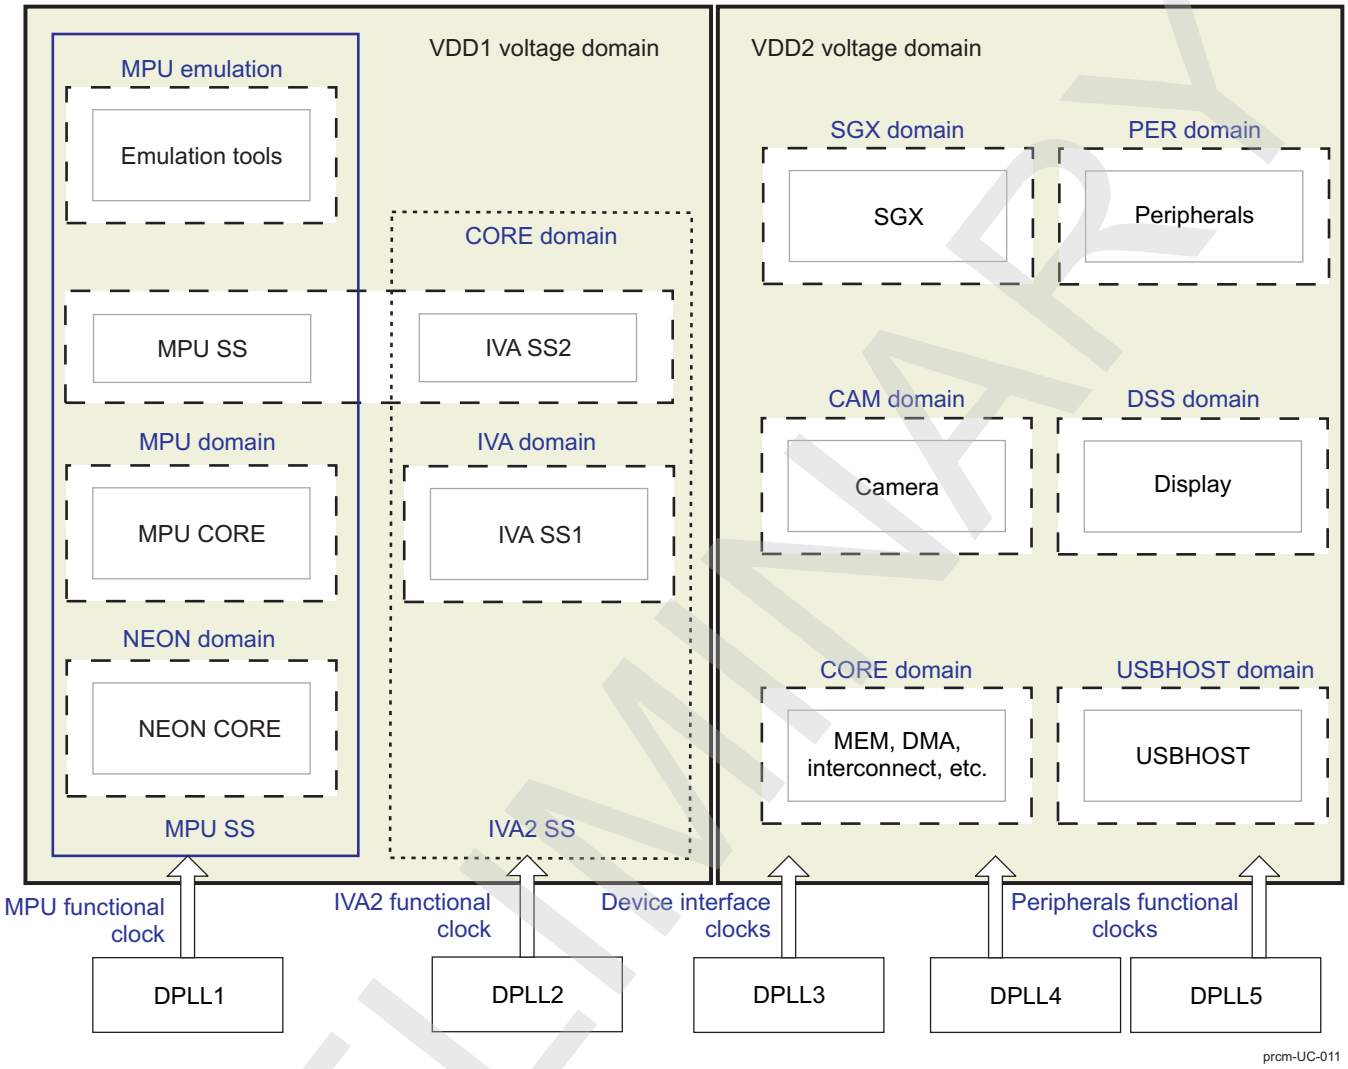
Figure 3-101. Overview of device/TWL5030 DVFS Management Architecture



3.7.1.1 Device DVFS Support Architecture

The device supports DVFS for two voltage domains, VDD1 and VDD2. The VDD1 voltage domain consists of the MPU and IVA2.2 subsystem sections with independent clocks generated by DPLL1 and DPLL2, respectively. The VDD2 voltage domain supports the CORE domain interconnects, memory, and DMA, and the camera, display, graphics, and peripheral power domain subsystems. DPLL3 and DPLL4 provide the clocks to the subsystems of VDD2 voltage domains (see Figure 3-102).

Figure 3-102. VDD1 and VDD2 Voltage Domain Modules and Clock Sources



Both VDD1 and VDD2 voltage domains support different operations and the clocks in these voltage domains can be scaled according to the operating performance points, as explained in Section 3.5.3.8.

3.7.1.2 TWL5030 DVFS Support Architecture

3.7.1.2.1 SMPS

The TWL5030 contains two SmartReflex-controllable SMPSs:

SMPS	Voltage Output	Voltage Step
VDD1	0.6 V to 1.45 V	12.5 mV
VDD2	0.6 V to 1.45 V	12.5 mV

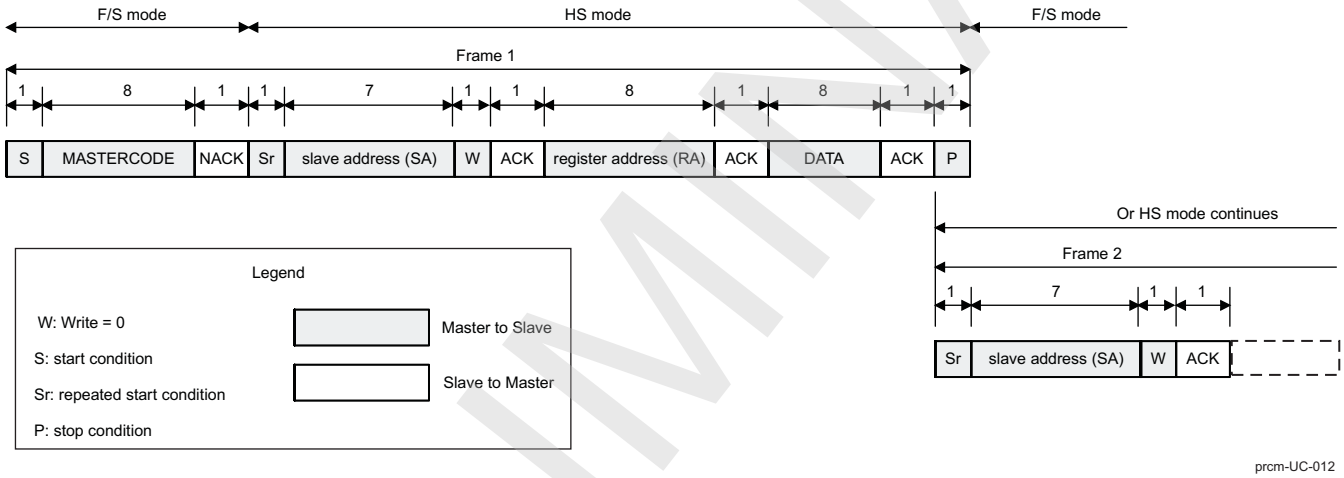
3.7.1.2.2 I²C Interface

To send data to a slave I²C, the I²C bus master sends a start condition and a master code to indicate its address as the master transmitter on the bus. This code is followed by a no-acknowledge from the receiver. The interface then switches from F/S mode to HS mode for HS transfer. The master then sends the repeated start-bit and I²C slave address of the device (the register group address in the case of TWL5030) for which the information is intended. In the 8-bit (1-byte) I²C address word, the least-significant bit (LSB) is used to indicate whether the I²C is a read or write process.

Following standard I²C protocol, the address byte is then followed by a data byte that the TWL5030 interprets as the address of a particular register within the register address group initially addressed by the I²C address byte. The I²C bus master then sends a second I²C data byte, which the TWL5030 loads into the register that is addressed. The command to the TWL5030 is executed when the particular internal register is loaded with the desired value (the TWL5030 acknowledges the byte immediately before loading the register).

Figure 3-103 shows the I²C communication protocol for the device and the TWL5030.

Figure 3-103. DeviceTWL5030 I²C Communication Protocol



SmartReflex I²C bus addressing in the TWL5030 uses one slave address that is hardcoded and dedicated to the SmartReflex registers:

I²C Address Group	Slave Address
ID5	12 hex

TWL5030 registers for SmartReflex control are clustered in the ID5 register address group. An individual register in the group is accessed by first selecting the register address group, and then the register address within the group.Table 3-92 lists the two registers in the ID5 register group.

Table 3-92. SmartReflex Voltage Control Registers in ID5 Register Group

Register	Register Address
VDD1_SR_CONTROL	0x0
VDD2_SR_CONTROL	0x1

The voltage control registers are configured by sending the 8-bit data to them. Table 3-93 lists the composition of the data.

Table 3-93. Data Composition for SmartReflex Voltage Control Registers

Bit	Function	Description	Reset Value
7	MODE	0x0: VDDx is in active mode. 0x1: VDDx is in sleep mode.	0x0

Table 3-93. Data Composition for SmartReflex Voltage Control Registers (continued)

Bit	Function	Description	Reset Value
6:0	VSEL	Output voltage Output voltage - VSEL * 12.5 mV + 0.6 V	0x30

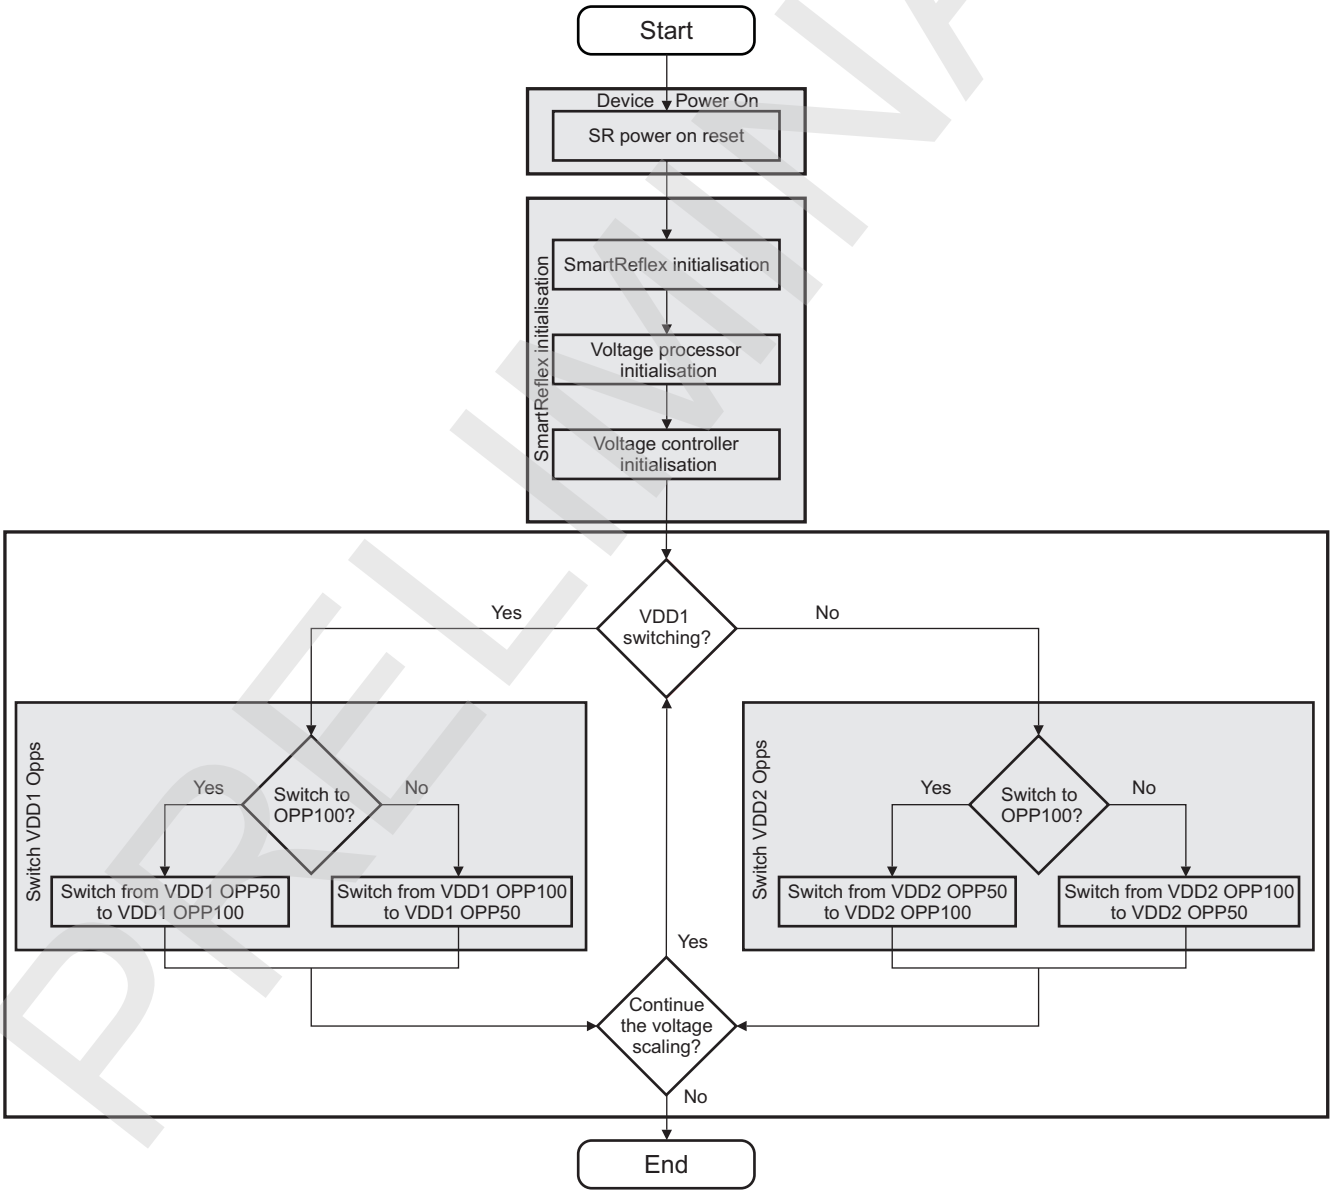
According to the reset value of the register, the VDDx is active and set to 1.2 V, where x can be 1 or 2.

For more information about the TWL5030, see the TWL5030 technical reference manual.

3.7.1.3 DVFS Using SmartReflex

This use case describes the initialization sequence of the SmartReflex voltage control part of the device and the TWL5030 power IC. It switches the OPP of the VDD1 and the VDD2 voltage channels (see Figure 3-104).

Figure 3-104. Device/TWL5030 SmartReflex DVFS Overview Flow Chart



3.7.1.3.1 Device SmartReflex Initialization

1. Initialize the SmartReflex module.

   Assuming that the SR_ALWON_FCLK has a frequency of 38.4 MHz, and the target SR_CLK frequency is 100 kHz (optimal frequency), the SRCLKLENGTH is set to 192 (0x0C0).

SRn.SRCONFIG[21:12] SRCLKLENGTH	0x0C0	Calculated from Equation 1
PRCM.CM_FCLKEN_WKUP[6] EN_SR1	0x1	SR1 functional clock enable
PRCM.CM_FCLKEN_WKUP[7] EN_SR2	0x1	SR2 functional clock enable

   Sensor core parameters are set and the sensor core is enabled.

SRn.SRCONFIG[1] SENNENABLE		Configured according to the settings in eFuse
SRn.SRCONFIG[4:3] SENPENABLE		See Section 3.5.6.5.4.5, *Parameter Configuration*.
SRn.SRCONFIG[10] SENENABLE	0x1	Enable the sensor module.

   Assuming that an accumulator time window of 5 ms is to be fixed and SR_CLK frequency is 100 kHz, the ACCUMDATA is 500 (0x1F4). The minimum/maximum/average block parameters are set and enabled.

SRn.SRCONFIG[31:22] ACCUMDATA	0x1F4	Calculated from Equation 2.
SRn.AVGWEIGHT[1:0] SENPAVGWEIGHT		Provided after silicon characterization
SRn.AVGWEIGHT[3:2] SENNAVGWEIGHT		
SRn.SRCONFIG[8] MINMAXAVGENABLE	0x1	Enable the minimum/maximum/average.

   Assuming that OPP130 is selected as the initial operating point for VDD1, and OPP100 is selected as the initial operating point for VDD2, the corresponding reciprocal reference value parameters are read from the corresponding eFuse data (see Section 3.5.6.5.4.5, *Parameter Configuration*).

SRn.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the settings in eFuse
SRn.NVALUERECIPROCAL[19:16] SENNGAIN		for the current operating voltage level
SRn.NVALUERECIPROCAL[15:8] RNSENP		See Section 3.5.6.5.4.5, *Parameter Configuration*.
SRn.NVALUERECIPROCAL[7:0] RNSENN		
SRn.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

   The interrupt generator parameters and interrupts are set. By default, all interrupts are masked. The voltage processor bounds interrupt is unmasked.

   For details about the interrupts, see Table 3-84.

SRn.ERRCONFIG[18:16] ERRWEIGHT		Provided after silicon characterization
SRn.ERRCONFIG[15:8] ERRMAXLIMIT		
SRn.ERRCONFIG[7:0] ERRMINLIMIT		
SRn.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the voltage processor bounds interrupt.
SRn.IRQENABLE_SET[1] MCUBOUNDSINTSTATENA	0x1	Enable the MCU valid interrupt.

2. Initialize the voltage processor.

   The error offset and gain values for the voltage converter are provided after system characterization.

PRCM.PRM_VPn_CONFIG[31:24] ERROROFFSET		Depends on the characteristics of the SMPS
PRCM.PRM_VPn_CONFIG[13:16] ERRORGAIN		

The step size of the SMPS for VDD1 and VDD2 is 12 mV. The minimum and maximum voltage steps are configured accordingly.

PRCM.PRM_VPn_VSTEPMIN[7:0] VSTEPMIN		Depends on the characteristics of the SMPS
PRCM.PRM_VPn_VSTEPMAX[7:0] VSTEPMAX		

Configure the acknowledge time-out delay, initial voltage values, and slew rates for the SMPS.

PRCM.PRM_VPn_VLIMITTO[15:0] TIMEOUT		Maximum amount of time to wait for the command acknowledge from the SMPS
PRCM.PRM_VP1_CONFIG[15:8] INITVOLTAGE	0x3C	1.26 V (VDD1 OPP130)
PRCM.PRM_VP2_CONFIG[15:8] INITVOLTAGE	0x2C	1.15 V (VDD2 OPP100)
PRCM.PRM_VPn_CONFIG[2] INITVDD	0x1	Asserts the initial voltage into the voltage processor FSM
PRCM.PRM_VPn_VSTEPMIN[23:8] SMPSWAITTIMEMIN		Depends on the characteristics of the SMPS
PRCM.PRM_VPn_VSTEPMAX[23:8] SMPSWAITTIMEMAX		

3. Initialize the voltage controller.

   Set the slave address (register group address) for the TWL5030 power IC SmartReflex register group (0x12). Because only one power IC is used, SA1 is not configured.

PRCM.PRM_VC_SMPS_SA[6:0] SA0	0x12	Register group ID5 of TWL5030

Set the voltage data configuration register address to that of the VDD1_SR_CONTROL and VDD2_SR_CONTROL registers of the TWL5030.

PRCM.PRM_VC_SMPS_VOL_RA[7:0] VOLRA0	0x0	VDD1_SR_CONTROL register address
PRCM.PRM_VC_SMPS_VOL_RA[23:16] VOLRA1	0x1	VDD2_SR_CONTROL register address

By default, the voltage controller pointers are configured to use the corresponding slave and register addresses assigned earlier.

By default, the I2C4 is configured in HS mode. Because the TWL5030 supports HS mode, there is no need to switch to F/S mode. Because the voltage processor transmits the individual voltage commands byte-by-byte, the repeated start operation is not necessary. Therefore, this mode is disabled.

PRCM.PRM_VC_I2C_CFG[2:0] MCODE	-	A master code for I^2C HS preamble
PRCM.PRM_VC_I2C_CFG[4] SREN	0x0	Disable the repeated start operation.

4. Enable the modules.

   Enable the voltage processor and SmartReflex modules.

PRCM.PRM_VPn_CONFIG[0] VPENABLE	0x1	Enable the voltage processor module.
SRn.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex module.

The valid interrupt of the MPU signals that the voltage has stabilized to within the limits.

3.7.1.3.2 Switch VDD1 OPPs

1. Switch from VDD1 OPP130 to VDD1 OPP100, assuming that
   - OPP130 (VDD1 = v2, (MPU_CLK = $f_{mpu}2$, IVA2_CLK = $f_{iva}2$))
   - OPP100 (VDD1 = v1, (MPU_CLK = $f_{mpu}1$, IVA2_CLK = $f_{iva}1$))

   and v2 > v1 , $f_{mpu}2 > f_{mpu}1$, $f_{iva}2 > f_{iva}1$.

   To switch from OPP130 to OPP100, the processor frequencies must be reduced before switching the voltage. The DPLL1 and DPLL2 frequencies are scaled by changing the multiplier and divider values. The DPLLs must relock, and they switch to bypass mode. DPLL frequency (F_{DPLL}) is calculated as:

   F_{DPLL} = (SYS_CLK*2*M)/(N+1)

   If SYS_CLK is 38.4 MHz, the values of M and N can be:

PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT	-	The multiplier and divider of DPLL1 are configured for OPP100 frequency.
PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV	-	
PRCM.CM_CLKSEL1_PLL_IVA2[18:8] IVA2_DPLL_MULT	-	The multiplier and divider of DPLL2 are configured for OPP50 frequency.
PRCM.CM_CLKSEL1_PLL_IVA2[6:0] IVA2_DPLL_DIV	-	

   The SmartReflex1 and voltage processor1 modules are disabled for voltage scaling.

SR1.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex1 module.
PRCM.PRM_VP1_CONFIG[0] VPENABLE	0x0	Disable the voltage processor1 module.

   The parameters of the error generator in the SmartReflex1 module are configured corresponding to OPP100.

SR1.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the settings in eFuse See Section 3.5.6.5.4.5, *Parameter Configuration*.
SR1.NVALUERECIPROCAL[19:16] SENNGAIN		
SR1.NVALUERECIPROCAL[15:8] RNSENP		
SR1.NVALUERECIPROCAL[7:0] RNSENN		
SR1.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

   The OPP change-done interrupt of voltage processor1 and the voltage processor bounds interrupt of the SmartReflex1 module are enabled. The remaining interrupts of the voltage processor and SmartReflex modules can be masked.

SR1.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the SmartReflex1 voltage processor interrupt.
PRCM.PRM_IRQENABLE_MPU VP1_OPPCHANGEDONE_EN	0x1	Enable the VP1 OPP change-done interrupt.

   The voltage processor1 and SmartReflex1 modules are enabled.

PRCM.PRM_VP1_CONFIG[0] VPENABLE	0x1	Enable the voltage processor1 module.
SR1.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex1 module.

   The SmartReflex1 module sends the OPP change-done interrupt when the OPP change is complete and the voltage is stable.

PRCM.PRM_IRQSTATUS_MPU[10] VP1_ OPPCHANGEDONE_ST	Read	On read, if this bit is 0x1, the OPP change is complete.
PRCM.PRM_IRQSTATUS_MPU[10] VP1_ OPPCHANGEDONE_ST	0x1	Writing 0x1 clears the interrupt status bit.

   Enable the voltage processor1 interrupt for automatic SmartReflex1 operation.

SR1.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the voltage processor bounds Interrupt.

2. Switch from VDD1 OPP100 to VDD1 OPP130, assuming that
   - OPP130 (VDD1 = v2, (MPU_CLK = $f_{mpu}2$, IVA2_CLK = $f_{iva}2$))
   - OPP100 (VDD1 = v1, (MPU_CLK = $f_{mpu}1$, IVA2_CLK = $f_{iva}1$))

   and v2 > v1, $f_{mpu}2 > f_{mpu}1$, $f_{iva}2 > f_{iva}1$.

   To switch from OPP100 to OPPTM, the domain voltage must be switched before the frequency

switching, because OPP130 has a higher frequency.

The SmartReflex1 and voltage processor1 modules are disabled for voltage scaling.

SR1.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex1 module.
PRCM.PRM_VP1_CONFIG[0] VPENABLE	0x0	Disable the voltage processor1 module.

The parameters of the SmartReflex1 error generator are configured corresponding to OPP130.

SR1.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the settings in eFuse See Section 3.5.6.5.4.5, *Parameter Configuration*.
SR1.NVALUERECIPROCAL[19:16] SENNGAIN		
SR1.NVALUERECIPROCAL[15:8] RNSENP		
SR1.NVALUERECIPROCAL[7:0] RNSENN		
SR1.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

The OPP change-done interrupt of the voltage processor1 and the voltage processor bounds interrupt of the SmartReflex1 module are enabled. The remaining interrupts of the voltage processor1 and SmartReflex1 modules can be masked.

SR1.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the SmartReflex1 voltage processor interrupt.
PRCM.PRM_IRQENABLE_MPU VP1_OPPCHANGEDONE_EN	0x1	Enable the VP1 OPP change-done interrupt.

The voltage processor1 and SmartReflex1 modules are enabled.

PRCM.PRM_VP1_CONFIG[0] VPENABLE	0x1	Enable the voltage processor1 module.
SR1.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex1 module.

The SmartReflex1 module sends the OPP change-done interrupt when the OPP change is complete and the voltage is stable.

PRCM.PRM_IRQSTATUS_MPU[10] VP1_ OPPCHANGEDONE_ST	Read	On read, if this bit is 0x1, the OPP change is complete.
PRCM.PRM_IRQSTATUS_MPU[10] VP1_ OPPCHANGEDONE_ST	0x1	Writing 0x1 clears the Interrupt status bit.

Enable the voltage processor1 interrupt for automatic SmartReflex1 operation.

SR1.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the voltage processor bounds interrupt.

After voltage switching is complete, the processor frequencies must be switched. The DPLL1 and DPLL2 frequencies are scaled by changing the multiplier and divider values. The DPLLs must relock and switch to bypass mode.

DPLL frequency (F_{DPLL}) is calculated as:

F_{DPLL} = (SYS_CLK*2*M)/(N+1)

If SYS_CLK is 38.4 MHz, the values of M and N can be set as:

PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT	-	The multiplier and divider of DPLL1 are configured for OPP130 frequency.
PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV	-	
PRCM.CM_CLKSEL1_PLL_IVA2[18:8] IVA2_DPLL_MULT	-	The multiplier and divider of DPLL2 are configured for OPP130 frequency.
PRCM.CM_CLKSEL1_PLL_IVA2[6:0] IVA2_DPLL_DIV	-	

3.7.1.3.3 Switch VDD2 OPPs

1. Switch from VDD2 OPP100 to VDD2 OPP50, assuming that
   - OPP100 (VDD2 = v3 , (DPLL3_CLKOUT = $f_{dpll3}3$, CORE_CLK = $f_{core}3$))
   - OPP50 (VDD2 = v2 , (DPLL3_CLKOUT = $f_{dpll3}2$, CORE_CLK = $f_{core}2$))

   and v3 > v2 , $f_{dpll3}3 > f_{dpll3}2$, $f_{core}3 > f_{core}2$.

   To switch from OPP100 to OPP50, the DPLL3 output divider must be configured to divide the output by 2. Frequency switching must be done before voltage switching.

PRCM. CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV	0x2	Configure the DPLL3 output divider for OPP50 CORE_CLK frequency.

The SmartReflex2 and voltage processor2 modules are disabled for voltage scaling.

SR2.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex2 module.
PRCM.PRM_VP2_CONFIG[0] VPENABLE	0x0	Disable the voltage processor2 module.

The reciprocal value and gain for the NAND and NOR counts are configured corresponding to OPP50.

SR2.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the settings in eFuse. See Section 3.5.6.5.4.5, *Parameter Configuration*.
SR2.NVALUERECIPROCAL[19:16] SENNGAIN		
SR2.NVALUERECIPROCAL[15:8] RNSENP		
SR2.NVALUERECIPROCAL[7:0] RNSENN		
SR2.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

The OPP change-done interrupt of the voltage processor and the voltage processor bounds interrupt of the SmartReflex module are enabled. The remaining interrupts of the voltage processor and SmartReflex modules can be masked.

SR2.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the SmartReflex2 voltage processor interrupt.
PRCM.PRM_IRQENABLE_MPU VP2_OPPCHANGEDONE_EN	0x1	Enable the VP2 OPP change-done interrupt.

The voltage processor2 and SmartReflex2 modules are enabled.

PRCM.PRM_VP2_CONFIG[0] VPENABLE	0x1	Enable the voltage processor2 module.
SR2.SRCONFIG[11] SR_EN	0x1	Enable the SmartReflex2 module.

The SmartReflex2 module sends the OPP change-done interrupt when the OPP change is complete and the voltage is stable.

PRCM.PRM_IRQSTATUS_MPU[16] VP2_ OPPCHANGEDONE_ST	Read	On read, if this bit is 0x,1 the OPP change is complete.
PRCM.PRM_IRQSTATUS_MPU[16] VP2_ OPPCHANGEDONE_ST	0x1	Writing 0x1 clears the interrupt status bit.

Enable the voltage processor2 bounds interrupt for automatic SmartReflex2 operation.

SR2.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the voltage processor bounds interrupt.

2. Switch from VDD2 OPP50 to VDD2 OPP100, assuming that
   - OPP100 (VDD2 = v3 , (DPLL3_CLKOUT = $f_{dpll3}3$, CORE_CLK = $f_{core}3$))
   - OPP50 (VDD2 = v2 , (DPLL3_CLKOUT = $f_{dpll3}2$, CORE_CLK = $f_{core}2$))

   and v3 > v2 , $f_{dpll3}3 > f_{dpll3}2$, $f_{core}3 > f_{core}2$.

   To switch from OPP50 to OPP100, the domain voltage must be switched before frequency switching, because OPP100 has a higher frequency.

   The SmartReflex2 and voltage processor2 modules are disabled for voltage scaling.

SR2.SRCONFIG[11] SR_EN	0x0	Disable the SmartReflex2 module.
PRCM.PRM_VP2_CONFIG[0] VPENABLE	0x0	Disable the voltage processor2 module.

The parameters of the error generator in the SmartReflex2 module are configured corresponding to OPP100.

SR2.NVALUERECIPROCAL[23:20] SENPGAIN		Configured according to the settings in eFuse. See Section 3.5.6.5.4.5, *Parameter Configuration*.
SR2.NVALUERECIPROCAL[19:16] SENNGAIN		
SR2.NVALUERECIPROCAL[15:8] RNSENP		
SR2.NVALUERECIPROCAL[7:0] RNSENN		
SR2.SRCONFIG[9] ERRORGENERATORENABLE	0x1	Enable the error generator.

The OPP change-done interrupt of the voltage processor2 and the voltage processor bounds interrupt of the SmartReflex2 module are enabled. The remaining interrupts of the voltage processor2 and SmartReflex2 modules can be masked.

SR2.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the SmartReflex2 voltage processor interrupt.
PRCM.PRM_IRQENABLE_MPU VP2_OPPCHANGEDONE_EN	0x1	Enable the VP2 OPP change-done interrupt.

The voltage processor2 and SmartReflex2 modules are enabled.

PRCM.PRM_VP2_CONFIG[0] VPENABLE	0x1	Enable the voltage processor module.
SR2.SRCONFIG [11] SR_EN	0x1	Enable the SmartReflex module.

The SmartReflex2 module sends the OPP change-done interrupt when the OPP change is complete and the voltage is stable.

PRCM.PRM_IRQSTATUS_MPU[10] VP2_ OPPCHANGEDONE_ST	Read	On read, if this bit is 0x1, the OPP change is complete.
PRCM.PRM_IRQSTATUS_MPU[10] VP2_ OPPCHANGEDONE_ST	0x1	Writing 0x1 clears the interrupt status bit.

Enable the voltage processor2 interrupt for automatic SmartReflex2 operation.

SR2.ERRCONFIG[22] VPBOUNDSINTENABLE	0x1	Enable the voltage processor bounds interrupt.

After voltage switching is complete, the core frequencies must be switched. Thus, the DPLL3 output divider is configured.

PRCM.CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV	0x1	Configure the DPLL3 output divider for OPP100 CORE_CLK frequency.

3.7.2 Voltage Control Using VMODE

3.7.2.1 Introduction

The PRCM module allows direct simple control of VDD1 and VDD2 through the dedicated signals sys_nvmode1 and sys_nvmode2. A single voltage value can be linked in the external power IC to a given state of sys_nvmode1 or sys_nvmode2. This allows direct voltage management (see Table 3-94).

Table 3-94. VDD1 and VDD2 Voltage Control Through VMODE

sys_nvmode Signals	Voltage Values	Comments
sys_nvmode1 is high.	VDD1 value 1	VDD1 value 1 depends on the power IC programming.
sys_nvmode1 is low.	VDD1 value 2	VDD1 value 2 depends on the power IC programming.
sys_nvmode2 is high.	VDD2 value 1	VDD2 value 1 depends on the power IC programming.
sys_nvmode2 is low.	VDD2 value 2	VDD2 value 2 depends on the power IC programming.

NOTE: The polarity of sys_nvmode1 and sys_nvmode2 is programmable. This means that the PRCM module sets them high or low, depending on the user settings. For this reason, the external power IC must be configured to provide a given voltage level depending on the states of the sys_nvmode*x* signals.

Assertion of sys_nvmode1 and sys_nvmode2 (low or high, depending on the chosen polarity) occurs immediately after a device sleep or wake-up transition. When the PRCM module triggers a sleep transition (ON to OFF, or ON to retention), it deasserts sys_nvmode1 and sys_nvmode2. When the PRCM module detects a device wake-up transition (retention to on, or off to on), it asserts sys_nvmode1 and sys_nvmode2.

NOTE: sys_nvmode1 and sys_nvmode2 are managed as one signal from the PRCM standpoint. In other words, their settings and assertion conditions are managed globally, without any granularity. The power IC software sets different values for VDD1 and VDD2, if necessary.

From the PRCM standpoint, using the VMODE signals is mutually exclusive with using the dedicated I2C4 interface to the external power IC; sys_nvmode*x* signals share the same physical interface as I2C4 at device boundary.

Using VMODE voltage control is an easy way to switch VDD1 and VDD2 voltage values upon device power state transitions. The following section gives the programming steps to achieve voltage management through VMODE signals.

3.7.2.2 Programming Sequence

3.7.2.2.1 Initialization Procedure

1. Configure sys_nvmode1 and sys_nvmode2 at the device level.

CONTROL.CONTROL_PADCONF_I2C4_SCL[15:0]	Mux mode1
CONTROL.CONTROL_PADCONF_I2C4_SCL[31:16]	Mux mode1

   The correct multiplexing mode is selected at the device level to select sys_nvmode1 and sys_nvmode2 on the balls. This is done in the SCM registers, as indicated. For further details, see Chapter 13, *System Control Module*.

2. Activate VMODE control.

PRM_VOLTCTRL[4] SEL_VMODE	0x1

   VMODE control is selected in the PRCM module. This also ensures the other interfaces to the power IC are correctly deactivated and managed.

3. Set the polarity of sys_nvmode1 and sys_nvmode2.

PRM_POLCTRL[0] EXTVOL_POL	0x1 => sys_nvmodex signals are active high

   Depending on the polarity set, the VMODE signals remain high or low until a transition is initiated. Their states then automatically toggle to the opposite state and return when the reverse transition is initiated.

4. Set the voltage stabilization delays.

PRM_VOLTSETUP1[31:16] SETUP_TIME2	VDD2 voltage stabilization time
PRM_VOLTSETUP1[15:0] SETUP_TIME1	VDD1 voltage stabilization time

   SETUP_TIME1 and SETUP_TIME2 are power IC-dependent parameters for voltage stabilization time for VDD1 and VDD2, respectively. For further details, see the power IC documentation.

5. Configure the power IC.

   This step relies entirely on power IC software settings. The purpose here is to link a voltage value to both VDD1 and VDD2 depending on the state of the sys_nvmode*x* signals. For further details, see the power IC documentation.

3.7.2.2.2 VMODE Signals Toggling

1. Has a sleep/wake-up transition been initiated?

   As stated previously, when VMODE voltage control is selected, the PRCM module automatically toggles sys_nvmode*x* signals and device sleep and wake-up transitions. This means the user has nothing more to control except the device transitions, as explained in this document. When a transition is initiated, sys_nvmode1 and sys_nvmode2 toggle according to their programmed polarity and alert the power IC to switch VDD1 and VDD2 to the programmed values.

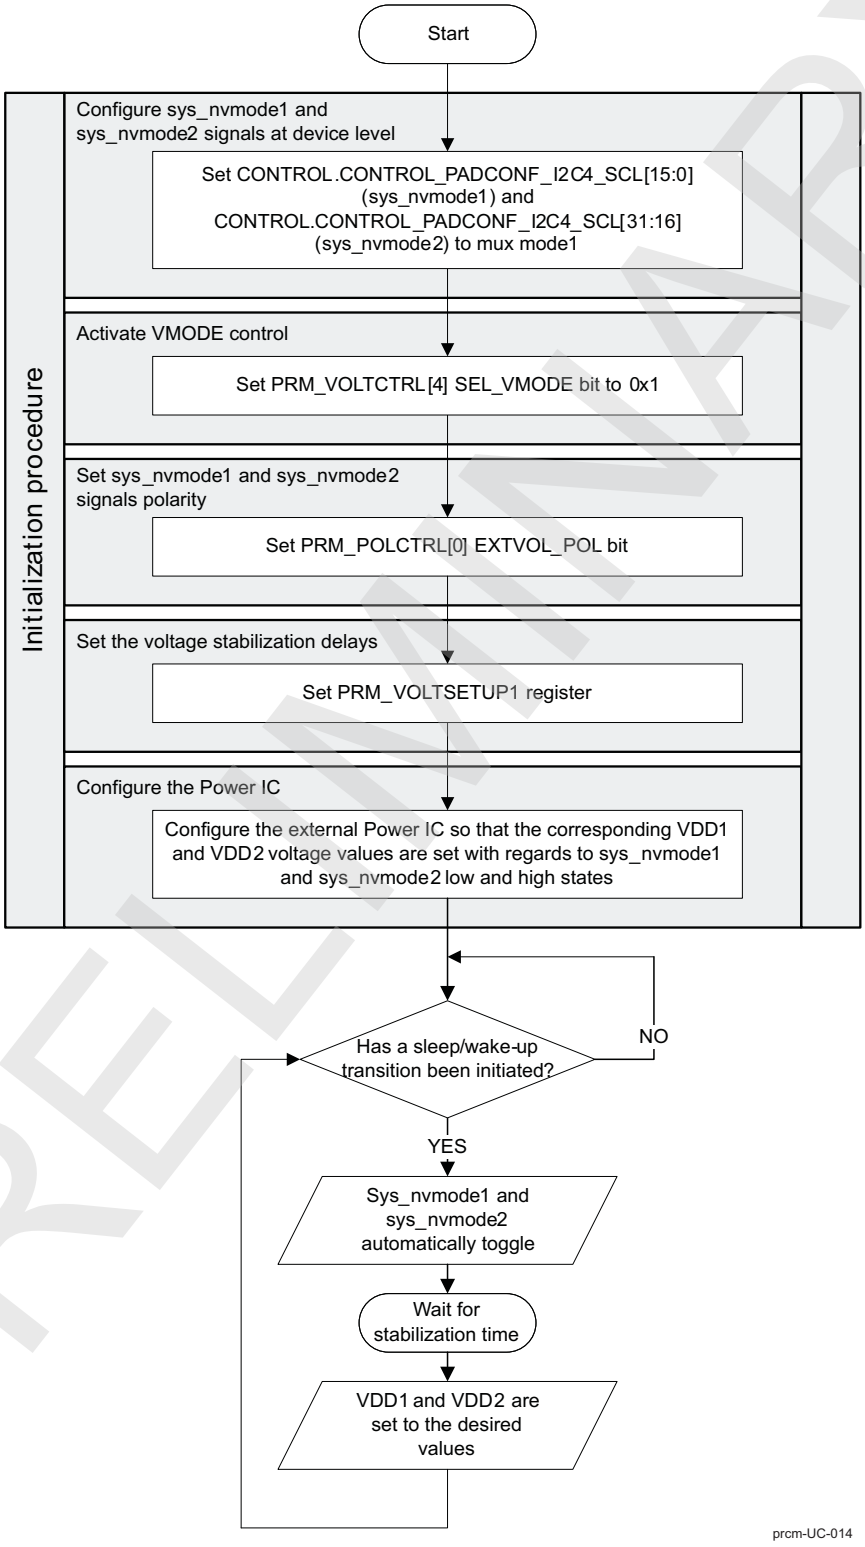
2. Wait for stabilization time.

   Depending on the SETUP_TIME1 and SETUP_TIME2 settings, the PRCM module starts a countdown immediately after the VMODE signal state changes. This ensures that the voltages provided by the power IC are stable before switching the device to the desired power state.

3.7.2.2.3 Summary Flow Chart

Figure 3-105 is a flow chart of VMODE voltage control.

Figure 3-105. Voltage Control Through VMODE Flow Chart



3.8 PRCM Register Manual

This section gives information about all modules and features in the high-tier device. For power-management saving consideration, ensure that power domains of unavailable features and modules are switched off and clocks are cut off.

Table 3-95 lists the Instance Summary of the CM modules. Table 3-96 through Table 3-294 provide register mapping summaries of the CM registers and describe the bits in the individual registers.

Table 3-296 lists the Instance Summary of the PRM modules. Table 3-297 through Table 3-535 provide register mapping summaries of the PRM registers and describe the bits in the individual registers.

3.8.1 CM Module Registers

3.8.1.1 CM Instance Summary

Table 3-95. CM Instance Summary

Module Name	Base Address (hex)	Size
IVA2_CM	0x4800 4000	8192 bytes

Bits	Field Name	Description	Type	Reset
31	PWRDN_EMU_PERIPH	This bit allows to power-down or not the DPLL4_M6_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M6_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M6_CLK HSDIVIDER path. Writting this bit to 1 will take effect immediatly.	RW	0x0
30	PWRDN_CAM	This bit allows to power-down or not the DPLL4_M5_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M5_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M5_CLK HSDIVIDER path. Writting this bit to 1 will take effect immediatly.	RW	0x0
29	PWRDN_DSS1	This bit allows to power-down or not the DPLL4_M4_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M4_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M4_CLK HSDIVIDER path. Writting this bit to 1 will take effect immediatly.	RW	0x0
28	PWRDN_TV	This bit allows to power-down or not the DPLL4_M3_CLK HSDIVIDER path. 0x0: Power-up the DPLL4_M3_CLK HSDIVIDER path. 0x1: Power-down the DPLL4_M3_CLK HSDIVIDER path. Writting this bit to 1 will take effect immediatly.	RW	0x0
27	PWRDN_96M	This bit allows to power-down or not the DPLL4_M2_CLK path. 0x0: Power-up the DPLL4_M2_CLK path. 0x1: Power-down the DPLL4_M2_CLK path. Writting this bit to 1 will take effect immediatly.	RW	0x0

Bits	Field Name	Description	Type	Reset
26	EN_PERIPH_DPLL_LPMODE	This bit allows to enable or disable the LP mode of the DPLL4. Writting this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL. 0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence. 0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.	RW	0x0
25:24	RESERVED		RW	0x0
23:20	RESERVED		RW	0x1
19	EN_PERIPH_DPLL_DRIFTGUARD	This bit allows to enable or disable the automatic recalibration feature of the DPLL4. The DPLL4 will automatically start a recalibration process upon assertion of the recal flag if this bit is set. 0x0: Disables the DPLL4 automatic recalibration mode 0x1: Enables the DPLL4 automatic recalibration mode	RW	0x0
18:16	EN_PERIPH_DPLL	DPLL4 control; Other enums: Reserved 0x1: Put the DPLL4 in low power stop mode 0x7: Enables the DPLL4 in lock mode	RW	0x1
15:13	RESERVED		R	0x0
12	PWRDN_EMU_CORE	This bit allows to power-down or not the DPLL3_M3X2 HSDIVIDER path. 0x0: Power-up the DPLL3_M3X2 HSDIVIDER path. 0x1: Power-down the DPLL3_M3X2 HSDIVIDER path. Writting this bit to 1 will take effect immediatly.	RW	0x0
11	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
10	EN_CORE_DPLL_LPMODE	This bit allows to enable or disable the LP mode of the DPLL3. Writting this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL. 0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence. 0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.	RW	0x0
9:8	RESERVED		RW	0x0
7:4	RESERVED	Reserved	RW	0x1
3	EN_CORE_DPLL_DRIFTGUARD	This bit allows to enable or disable the automatic recalibration feature of the DPLL3. The DPLL3 will automatically start a recalibration process upon assertion of the recal flag if this bit is set. 0x0: Disables the DPLL3 automatic recalibration mode 0x1: Enables the DPLL3 automatic recalibration mode	RW	0x0
2:0	EN_CORE_DPLL	DPLL3 control; Other enums: Reserved 0x5: Put the DPLL3 in low power bypass 0x6: Put the DPLL3 in fast relock bypass 0x7: Enables the DPLL3 in lock mode	RW	0x5

Description	This register controls the selection of the master clock frequencies.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SD_DIV								DCO_SEL			RESERVED	PERIPH_DPLL_MULT												RESERVED	PERIPH_DPLL_DIV							

Bits	Field Name	Description	Type	Reset
31:24	SD_DIV	This register bits field allows setting the sigma-delta divider factor of the PERIPHERAL DPLL. It must be comprise between 2 and 255. The values 0 and 1 are reserved.	RW	0x02
23:21	DCO_SEL	This register bits field allows selecting the DCO used by the PERIPHERAL DPLL to synthesize its output clock; Other enums: Reserved 0x2: The lock frequency is comprised between 500 MHz and 1000 MHz. 0x4: The lock frequency is comprised between 1000 MHz and 2000 MHz.	RW	0x2
20	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0000
19:8	PERIPH_DPLL_MULT	DPLL4 multiplier factor (0 to 4095)	RW	0x000
7	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
6:0	PERIPH_DPLL_DIV	DPLL4 divider factor (0 to 127)	RW	0x00

Table 3-233. CM_IDLEST_CAM

Address Offset	0x0000 0020		
Physical Address	0x4800 4F20	**Instance**	CAM_CM
Description	Modules access availability monitoring. This register is read only and automatically updated.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															ST_CAM

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Read returns 0.	R	0x00000000
0	ST_CAM	Camera standby status. 0x0: Camera is active. 0x1: Camera is in standby mode.	R	0x1

Table 3-234. Register Call Summary for Register CM_IDLEST_CAM

PRCM Basic Programming Model • CM_IDLEST_ <domain_name> (Idle-Status Register): [0]
PRCM Register Manual • CAM_CM Register Summary: [1]

Table 3-235. CM_AUTOIDLE_CAM

Address Offset	0x0000 0030		
Physical Address	0x4800 4F30	**Instance**	CAM_CM
Description	This register controls the automatic control of the modules interface clock activity.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																															AUTO_CAM

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x00000000
0	AUTO_CAM	Camera auto clock control. 0x0: Camera clock is unrelated to the domain state transition. 0x1: Camera clock is automatically enabled or disabled along with the domain state transition.	RW	0x0

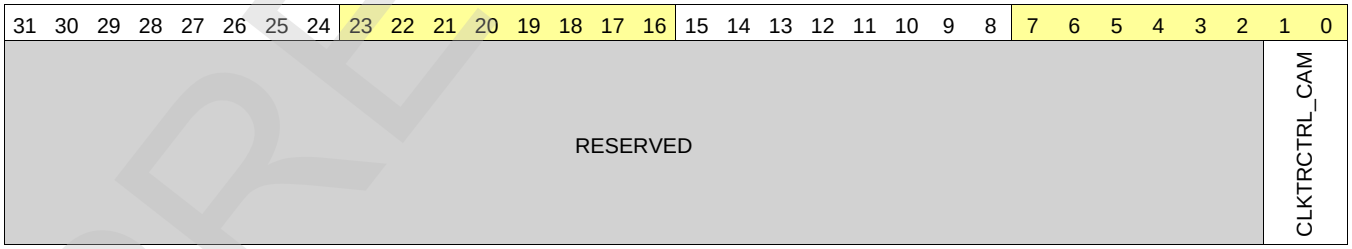
PRCM Basic Programming Model
- CM_SLEEPDEP_ <domain_name> (Sleep Dependency Control Register): [0]

PRCM Register Manual
- CAM_CM Register Summary: [1]

Table 3-241. CM_CLKSTCTRL_CAM

Address Offset	0x0000 0048		
Physical Address	0x4800 4F48	**Instance**	CAM_CM
Description	This register allows to enable or disable SW and HW supervised transition between ACTIVE and INACTIVE states.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x00000000
1:0	CLKTRCTRL_CAM	Controls the clock state transition of the CAMERA clock domain. 0x0: Automatic transition is disabled 0x1: Start a software supervised sleep transition on the domain 0x2: Start a software supervised wake-up transition on the domain 0x3: Automatic transition is enabled. Transition is supervised by the hardware.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x00
28	VC_BYPASS_ACK_ST	Voltage controller's acknowledge to the bypass interface status. It is cleared by software. Read 0x0: Voltage controller's acknowledge to the bypass interface event is false. Write 0x0: Status bit unchanged. Read 0x1: Voltage controller's acknowledge to the bypass interface event is true (pending). Write 0x1: Status bit is cleared to 0.	RW dual	0
27	VC_VP1_ACK_ST	Voltage controller's acknowledge to the VDD1 voltage processor status. It is cleared by software. Read 0x0: Voltage controller's acknowledge to the VDD1 voltage processor event is false. Write 0x0: Status bit unchanged. Read 0x1: Voltage controller's acknowledge to the VDD1 voltage processor event is true (pending). Write 0x1: Status bit is cleared to 0.	RW dual	0
26	ABB_LDO_TRANXDONE_ST	ABB LDO transaction completion status. This status is set when a software-initiated transaction is completed in ABB LDO (active mode transition only). It is cleared by software. Read 0x0: ABB LDO transaction done event is false. Write 0x0: Status bit unchanged. Read 0x1: ABB LDO transaction done event is true (pending). Write 0x1: Status bit is cleared to 0.	RW dual	0
25	SND_PERIPH_DPLL_ST	DPLL5 recalibration event status Read 0x0: DPLL5 recalibration event is false Write 0x0: Status bit unchanged Read 0x1: DPLL5 recalibration event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
24	VC_TIMEOUTERR_ST	Voltage Controller timeout error event status Read 0x0: Voltage Controller timeout error event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Controller timeout error event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
23	VC_RAERR_ST	Voltage Controller register address acknowledge error event status Read 0x0: Voltage Controller register address acknowledge error event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Controller register address acknowledge error event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
22	VC_SAERR_ST	Voltage Controller slave address acknowledge error event status Read 0x0: Voltage Controller slave address acknowledge error event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Controller slave address acknowledge error event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	VP2_TRANXDONE_ST	Voltage Processor 2 transaction completion status. This status is set when a transaction is completed in the voltage processor. It is cleared by software. Read 0x0: Voltage Processor 2 transaction done event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 transaction done event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
20	VP2_EQVALUE_ST	Voltage Processor 2 voltage value change event. This status is set when an update has been requested but the new voltage value is the same as the current SMPS voltage value. It is cleared by software. Read 0x0: Voltage Processor 2 no voltage value change event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 no voltage value change event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
19	VP2_NOSMPSACK_ST	Voltage Processor 2 timeout event status. This status is set when the timeout occured before the SMPS acknowledge. It is cleared by SW. Read 0x0: Voltage Processor 2 timeout event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 timeout event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
18	VP2_MAXVDD_ST	Voltage Processor 2 voltage higher limit event status. This status is set when the voltage higher limit is reached. It is cleared by SW. Read 0x0: Voltage Processor 2 voltage higher limit event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 voltage higher limit event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
17	VP2_MINVDD_ST	Voltage Processor 2 voltage lower limit event status. This status is set when the voltage lower limit is reached. It is cleared by SW. Read 0x0: Voltage Processor 2 voltage lower limit event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 voltage lower limit event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
16	VP2_OPPCHANGEDONE_ST	Voltage Processor 2 OPP change done status. Read 0x0: Voltage Processor 2 OPP change done event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 2 OPP change done event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
15	VP1_TRANXDONE_ST	Voltage Processor 1 transaction completion status. This status is set when a transaction is completed in the voltage processor. It is cleared by SW. Read 0x0: Voltage Processor 1 transaction done event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 transaction done event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
14	VP1_EQVALUE_ST	Voltage Processor 1 voltage value change event. This status is set when an update has been requested but the new voltage value is the same as the current SMPS voltage value. It is cleared by SW. Read 0x0: Voltage Processor 1 no voltage value change event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 no voltage value change event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
13	VP1_NOSMPSACK_ST	Voltage Processor 1 timeout event status. This status is set when the timeout occured before the SMPS acknowledge. It is cleared by SW. Read 0x0: Voltage Processor 1 timeout event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 timeout event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
12	VP1_MAXVDD_ST	Voltage Processor 1 voltage higher limit event status. This status is set when the voltage higher limit is reached. It is cleared by SW. Read 0x0: Voltage Processor 1 voltage higher limit event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 voltage higher limit event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
11	VP1_MINVDD_ST	Voltage Processor 1 voltage lower limit event status. This status is set when the voltage lower limit is reached. It is cleared by SW. Read 0x0: Voltage Processor 1 voltage lower limit event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 voltage lower limit event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
10	VP1_OPPCHANGEDONE_ST	Voltage Processor 1 OPP change done status. Read 0x0: Voltage Processor 1 OPP change done event is false Write 0x0: Status bit unchanged Read 0x1: Voltage Processor 1 OPP change done event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
9	IO_ST	IO pad event status Read 0x0: IO pad event is false Write 0x0: Status bit unchanged Read 0x1: IO pad event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
8	IVA2_DPLL_ST	IVA2 DPLL recalibration event status Read 0x0: IVA2 DPLL recalibration event is false Write 0x0: Status bit unchanged Read 0x1: IVA2 DPLL recalibration event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
7	MPU_DPLL_ST	DPLL1 recalibration event status Read 0x0: DPLL1 recalibration event is false Write 0x0: Status bit unchanged Read 0x1: DPLL1 recalibration event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
6	PERIPH_DPLL_ST	DPLL4 recalibration event status Read 0x0: DPLL4 recalibration event is false Write 0x0: Status bit unchanged Read 0x1: DPLL4 recalibration event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
5	CORE_DPLL_ST	DPLL3 recalibration event status Read 0x0: DPLL3 recalibration event is false Write 0x0: Status bit unchanged Read 0x1: DPLL3 recalibration event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
4	TRANSITION_ST	Software supervised transition completed event status Read 0x0: Software supervised transition completed event is false Write 0x0: Status bit unchanged Read 0x1: Software supervised transition completed event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
3	EVGENOFF_ST	Event Generator endOFFtime status Read 0x0: End of OFF time event is false Write 0x0: Status bit unchanged Read 0x1: End of OFF time event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
2	EVGENON_ST	Event Generator endONtime status Read 0x0: End of ON time event is false Write 0x0: Status bit unchanged Read 0x1: End of ON time event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x0
0	WKUP_ST	MPU peripherals group wake-up event status Read 0x0: Wake-up event is false Write 0x0: Status bit unchanged Read 0x1: Wake-up event is true (pending) Write 0x1: Status bit is cleared to 0.	RW	0x0

Table 3-321. PRM_IRQENABLE_MPU

Address Offset	0x0000 001C		
Physical Address	0x4830 681C	**Instance**	OCP_System_Reg_PRM
Description	The interrupt enable register allows masking/unmasking the module internal sources of interrupt, on a event-by-event basis. This registers applies on the interrupt line 0 mapped to the MPU interrupt controller.		
Type	RW

PRCM Basic Programming Model
- PM_PWSTCTRL_ <domain_name> (Power State Control Register): [8]

PRCM Register Manual
- CORE_PRM Register Summary: [9]
- CORE_PRM Registers: [10] [11]

NOTE: Before initiating a domain sleep transition (ON to OFF) on the MPU and CORE power domains, the CORE memory banks must be configured to automatically switch to ON power state when the CORE power domain wakes up (OFF to ON). This is required for correct booting.

This is done by setting the PM_PWSTCTRL_CORE [19:18] MEM2ONSTATE bit field to 0x3 and the PM_PWSTCTRL_CORE [17:16] MEM1ONSTATE bit field to 0x3."

Table 3-355. PM_PWSTST_CORE

Table 3-461. PRM_VOLTCTRL

Address Offset	0x0000 0060		
Physical Address	0x4830 7260	**Instance**	Global_Reg_PRM
Description	This register allows a direct control on the external power IC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							PAD_OFF_MODE_OVR	RESERVED				SEL_VMODE	SEL_OFF	AUTO_OFF	AUTO_RET	AUTO_SLEEP

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000000
8	PAD_OFF_MODE_OVR	This bit selects the release condition of the signal PAD_OFF_MODE. 0x0: The release of the signal PAD_OFF_MODE occurs immediatly after completion of the HW restore. 0x1: The release of the signal PAD_OFF_MODE occurs when the software clears this bit. Writing this bit to 1 has no effect on the signal assertion.	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
4	SEL_VMODE	This bit allows to select the mode used to control the Power IC (I2C or VMODE). 0x0: The Power IC is controlled through the SR dedicated I2C interface. 0x1: The Power IC is controlled through the VMODE interface.	RW	0x0
3	SEL_OFF	This bit allows to select the mode used to send the OFF command. 0x0: The OFF command is send through the voltage controller I2C interface. 0x1: The signal SYS.OFF_MODE is asserted.	RW	0x0
2	AUTO_OFF	This bit allows to send an OFF command to the Power IC. 0x0: The OFF command is not send. 0x1: The OFF command is automatically send when the voltage domain is in the appropriate standby mode.	RW	0x0
1	AUTO_RET	This bit allows to send a RETENTION command to the Power IC through the voltage controller I2C interface. 0x0: The RETENTION command is not send. 0x1: The RETENTION command is automatically send when the voltage domain is in the appropriate standby mode.	RW	0x0
0	AUTO_SLEEP	This bit allows to send a SLEEP command to the Power IC through the voltage controller I2C interface. 0x0: The SLEEP command is not send. 0x1: The SLEEP command is automatically send when the voltage domain is in the appropriate standby mode.	RW	0x0

MPU Subsystem

This chapter describes the microprocessor unit (MPU) subsystem.

Topic **Page**

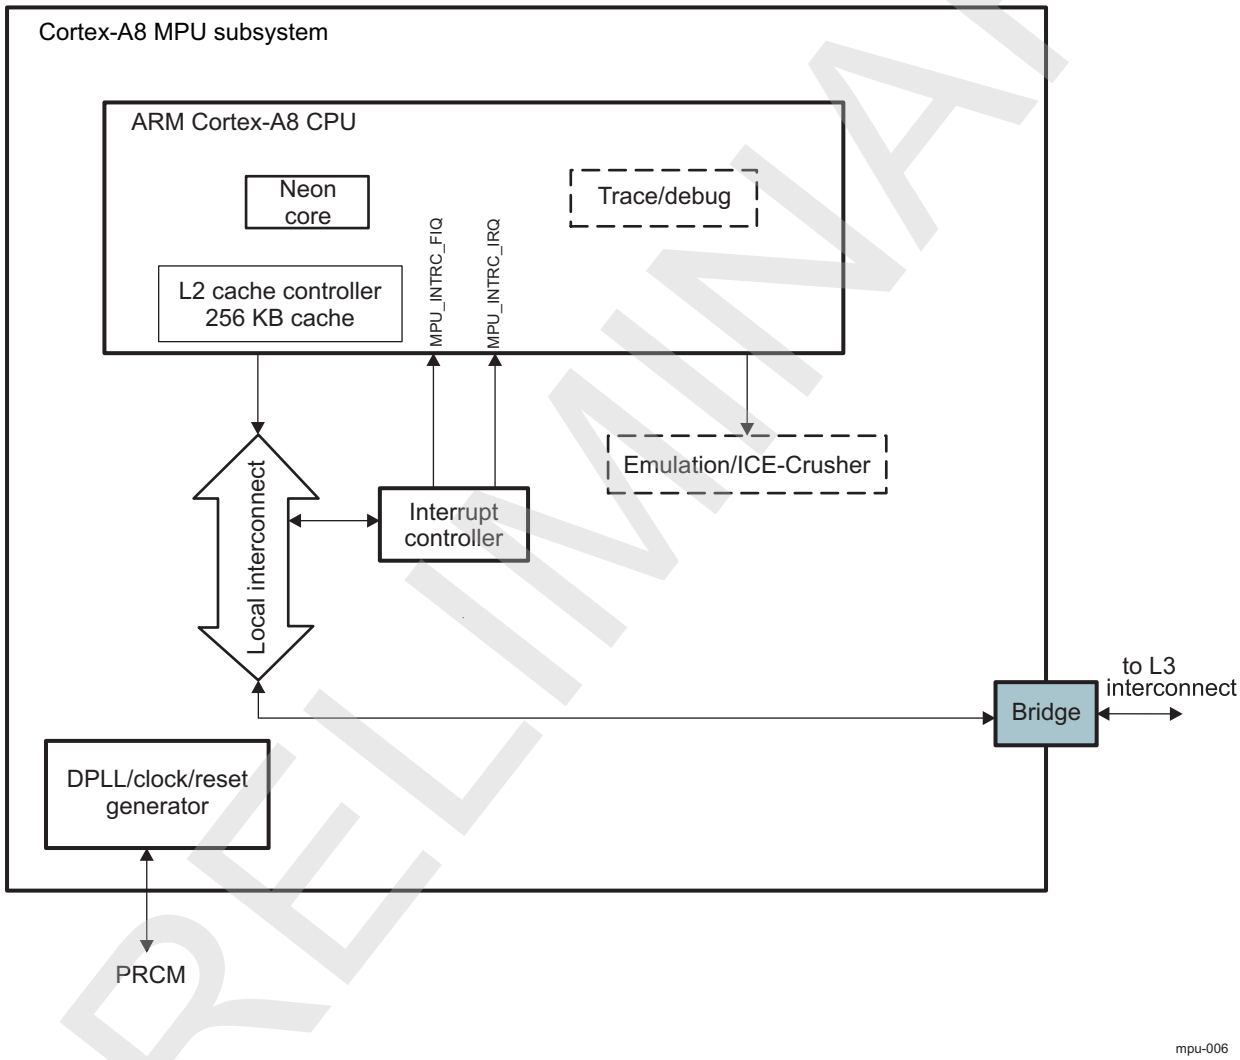
4.1 MPU Subsystem Overview

4.1.1 Introduction

The MPU subsystem of the device handles transactions among the ARM® core, the L3 interconnect, and the interrupt controller (INTC).

The MPU subsystem is hard-macro, thus integrating the ARM subchip with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements. Figure 4-1 shows the high-level block diagram of the MPU subsystem.

Figure 4-1. MPU Subsystem Overview



4.1.2 Features

The MPU subsystem integrates the following:

- ARM subchip
  - ARM Cortex™-A8 core revision r3p2. For more information, refer to the ARM Cortex-A8 TRM.
  - ARM Version 7 ISA™: Standard ARM instruction set + Thumb®-2, JazelleX™ Java™ accelerator, and media extensions
  - ARM NEON™ core - single instruction, multiple data (SIMD) coprocessor (VFP light + media streaming instructions)
  - Cache memories

    - Level 1: 32KB instruction and 32KB data caches - 4 ways associative, 64 bytes/line
    - Level 2: L2 cache and cache controller are embedded within the ARM Cortex-A8 CPU - 256KB, 8 ways associative, 64 bytes/line, parity and error-correction code (ECC) supported
  - Memory management unit (MMU) and translation look-aside buffers (TLBs) - separate instruction and data TLB, 32 entries each
  - integrated trace and debug features
- Interrupt controller (INTC) - allows up to 96 level-sensitive interrupt inputs (For details, see Chapter 12, *Interrupt Controller*.)
- Local interconnect between ARM Cortex-A8 CPU, Interrupt controller, and L3 interconnect
- Clock generation and control module - generates clocks, power modes, and idle and active acknowledge signals
- Emulation features: ICECrusher™, Embedded Trace Macrocell™ (ETM™). The Cortex-A8 MPU implements an APB (Advanced Peripheral Bus) slave interface that allows access to ETM, ICECrusherCS and debug registers.

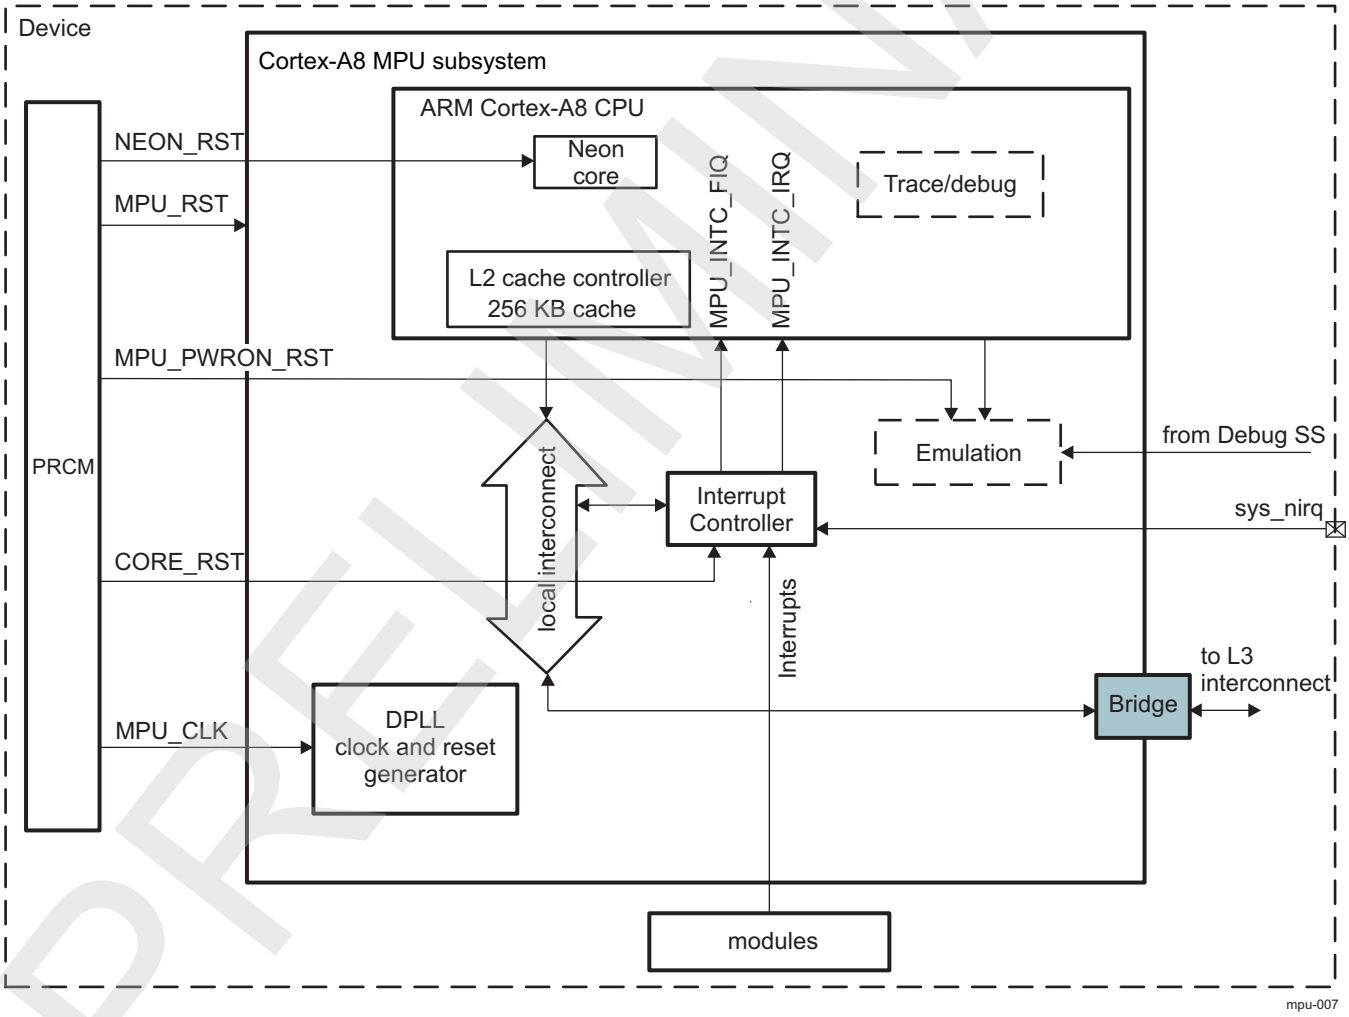
4.2 MPU Subsystem Integration

The MPU subsystem integrates a group of submodules:

- ARM Cortex-A8 CPU, which provides high-processing capability; this submodule includes the NEON technology for mobile multimedia acceleration. The ARM CPU receives interrupts from the MPU subsystem interrupt controller (MPU INTC).
- Interrupt controller that handles device module interrupts (For details, see Chapter 12, *Interrupt Controller*.)
- Local interconnect between ARM Cortex-A8 CPU, Interrupt controller, and L3 interconnect
- MPU clock generator: Provides clocks to internal modules of the MPU subsystem; fed by the MPU digital phase-locked loop (DPLL) of the power, reset, and clock management (PRCM) module of the device. The MPU DPLL generates clock for the ARM Cortex-A8 CPU and the Cortex-A8 MPU subsystem logic. All power, reset and the MPU DPLL source clock is generated from the device PRCM.

Figure 4-2 shows the signals that interface with the external modules.

Figure 4-2. MPU Subsystem Integration Overview



NOTE: Some debug, trace, and emulation features are implemented in the MPU subsystem. Only the clock/reset inputs and power management aspects of these features are listed in this chapter. For details, see the Emulation TRM.

4.2.1 MPU Subsystem Clock and Reset Distribution

4.2.1.1 Clock Distribution

The MPU subsystem includes a clock generator block that supplies clocks for the modules in the MPU subsystem. It is fed by the MPU_CLK clock from the PRCM module.

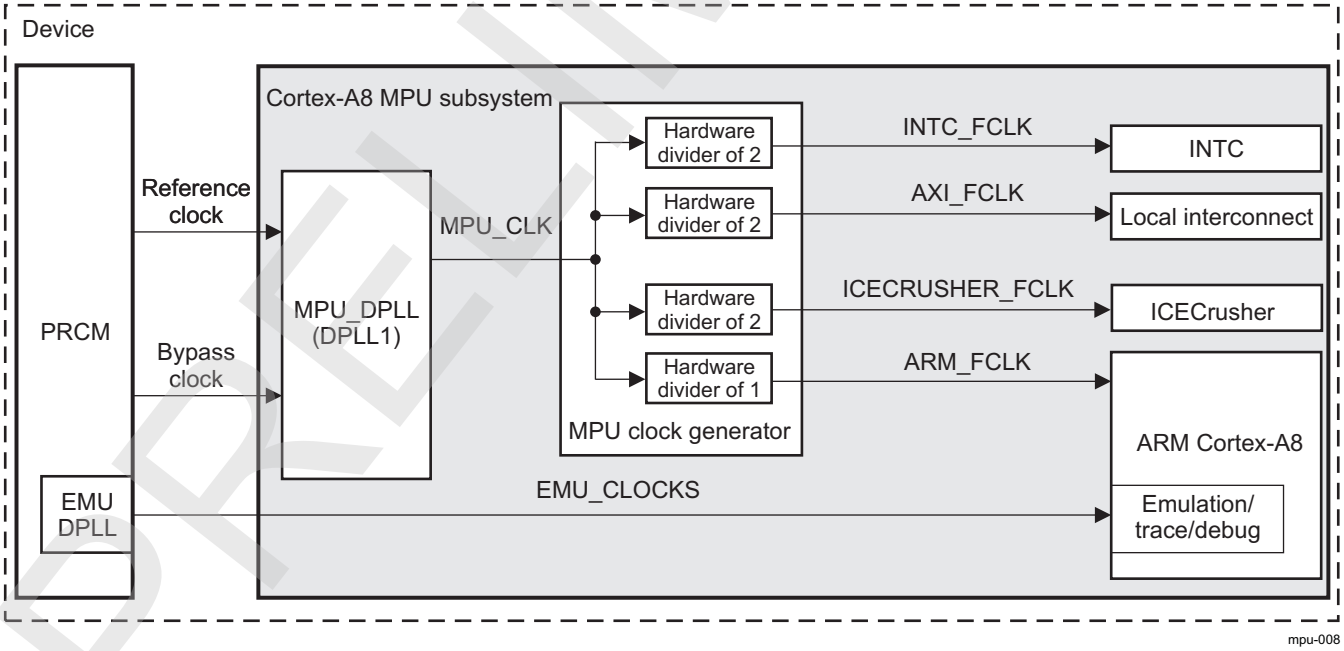
All major modules in the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV bit field; the frequency is relative to the ARM core. For details, see Chapter 3, *Power, Reset, and Clock Management*. The clock generator generates the following functional clocks:

- **ARM (ARM_FCLK):** This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including NEON, L2 cache, the ETM core (emulation), and the ARM core. It runs at the frequency of the MPU_CLK when DPLL1 is locked, and runs as the frequency of the bypass clock when DPLL1 is bypassed.
- **Local interconnect clock (AXI_FCLK):** This clock is half the frequency of the MPU clock (MPU_CLK). The L3 interconnect interface thus performs at one half the frequency of the MPU.
- **Interrupt Controller Functional Clock (MPU_INTC_FCLK):** This clock, which is part of the INTC module, is half the frequency of the MPU clock (MPU_CLK).
- **ICECrusher™ Functional Clock (ICECRUSHER_FCLK):** ICECrusher clocking operates on the APB interface, using the ARM core clocking. For details, see the Emulation TRM.

Emulation Clocking: Except for the ICECrusher functional clock, which is provided by the MPU DLL, the emulation modules inside the MPU subsystem are not generated by the MPU subsystem DPLL, but by an EMU DPLL. These clocks (EMU_CLOCKS) are distributed by the device PRCM module, are asynchronous to the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock. For details, see the Emulation TRM.

Figure 4-3 shows the MPU subsystem clocking scheme.

Figure 4-3. MPU Subsystem Clocking Scheme



For more information about MPU_DPLL, see Section 3.5.3.3.3, *DPLLs*, in Chapter 3, *Power, Reset, and Clock Managment*.

Table 4-1 summarizes the clocks generated in the MPU subsystem by the MPU DPLL and clock generator.

Table 4-1. MPU DPLL Clock Signals

Signal Name	I/O	Interface	Comments
MPU_CLK	I	PRCM	MPU DPLL clock
ARM_FCLK	O	ARM	ARM functional clock
MPU_INTC_FCLK	O	MPU INTC	MPU INTC functional clock
AXI_FCLK	O	Local interconnect	Local interconnect functional clock
ICECRUSHER_FCLK	O	ICECrusher	ICECrusher functional clock

4.2.1.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM and controlled by the clock generator module. There are as many reset signals as power domains. For details about power domains, see Section 4.3.2.1. Figure 4-4 shows the reset scheme of the MPU subsystem.

Figure 4-4. MPU Subsystem Reset Scheme

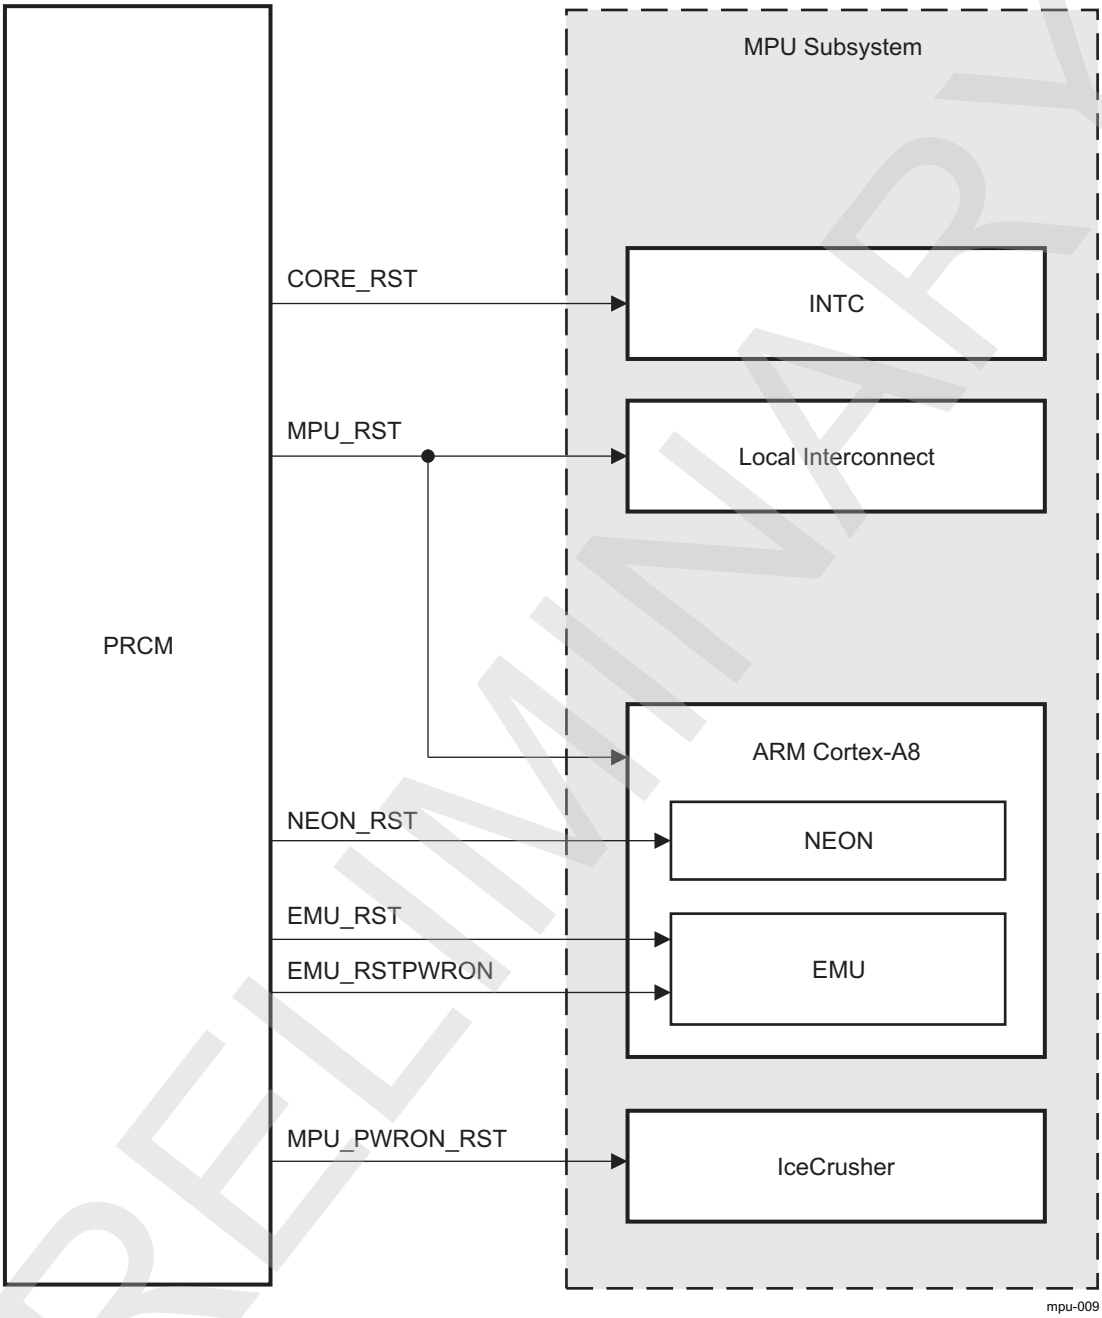


Table 4-2. MPU Subsystem Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
NEON_RST	I	PRCM	NEON power domain reset
CORE_RST	I	PRCM	CORE power domain reset
MPU_PWRON_RST	I	PRCM	ICECrusher reset. It is active upon a Cold reset only.
EMU_RST	I	PRCM	Emulation interconnect reset
EMU_RSTPWRON	I	PRCM	Emulation modules reset

For details about clocks, resets, and power domains, see Chapter 3, *Power, Reset, and Clock Management*.

4.2.2 ARM Subchip

4.2.2.1 ARM Overview

The ARM Cortex-A8 processor incorporates the technologies available in the ARMv7 architecture. These technologies include NEON for media and signal processing and Jazelle® Runtime Compilation Target (RCT) for acceleration of realtime compilers, Thumb-2 technology for code density and the VFPv3 floating point architecture. For details, see the ARM Cortex-A8 Technical Reference Manual.

4.2.2.2 ARM Description

4.2.2.2.1 ARM Cortex-A8 Instruction, Data, and Private Peripheral Port

The CPU bus interface to the local interconnect is the main interface to the ARM system bus. It performs L2 cache fills and non-cacheable accesses for both instructions and data. The bus interface supports 64-bit wide input and output data buses.

See the ARM Cortex-A8 Technical Reference Manual for a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address.

4.2.2.2.2 MPU Subsystem Features

Table 4-3 is a lists the main functionalities of the ARM core supported in the MPU subsystem of the device. The MPU subsystem implements the ARM Version 7 Instruction Set Architecture (ISA).

Table 4-3. ARM Core Key Features

Feature	Comment
ARM version 7 ISA	Standard ARM instruction set + Thumb-2, JazelleX Java accelerator, and Media extensions. Backward-compatible with previous ARM ISA versions.
L1 Icache and Dcache	32KB, 4-way, 64-byte cache line, 128 bit interface for Icache and 64 bit interface for Dcache. Note: L1 memories cannot be put into retention mode.
L2 cache	The L2 cache and cache controller are embedded in the ARM core. 256KB , 8-way, 64 bytes cache line size, 128 bit interface to L1 cache.
TLB	Fully associative and separate ITLB with 32 entries and DTLB with 32 entries
CoreSight™ ETM	The CoreSight ETM is embedded in the ARM core. The 4KB buffer (ETB) exists at the device level. For details, see the Emulation TRM.
Branch target address cache	512 entries
Enhanced Memory Management Unit (MMU)	Mapping sizes are 4KB, 64KB, 1MB, and 16MB. ARM MMU adds extended physical address ranges.
NEON	Enhances throughput for media workloads and VFP-Lite support
Low interrupt latency	Possible via a closely coupled INTC to the Cortex-A8 core
Vectored Interrupt Controller Port	Present
JTAG based debug	Supported through DAP
Trace support	Supported through TPIU
External coprocessor	Not supported

For more information, see the *ARM Cortex-A8 Technical Reference Manual*.

4.2.2.3 Clock, Reset, and Power Management

4.2.2.3.1 Clocks

Table 4-4 describes the ARM functional clock. For configuration, see Chapter 3, *Clock, Reset, and Power Management*.

Table 4-4. MPU Subsystem Clock Signal

Signal Name	I/O	Interface	Comments
ARM_FCLK	I	MPU clock generator	Functional clock

4.2.2.3.2 Reset

Table 4-5 lists the resets for the ARM. They include the power domains reset; NEON_RST, which resets the neon module of the ARM subchip only; and MPU_RST, which resets the rest of the ARM subchip and also the local interconnect.

Table 4-5. ARM Reset Signals

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset
NEON_RST	I	PRCM	Reset NEON only
EMU_RST	I	PRCM	Emulation interconnect reset
EMU_RSTPWRON	I	PRCM	Emulation modules reset

4.2.2.3.3 Power Management

For details, see Section 4.3.2.

4.2.3 Local Interconnect

4.2.3.1 Description

The local interconnect inside the MPU connects the ARM Cortex-A8 CPU, Interrupt controller, and L3 interconnect.

4.2.3.2 Clocks, Reset, and Power Management

4.2.3.2.1 Clocks

Table 4-6 lists the bridge functional clocks.

Table 4-6. Bridges Clock Signals

Signal Name	I/O	Interface	Comments
AXI_FCLK	I	MPU clock generator	functional clock

4.2.3.2.2 Reset

Table 4-7 lists the bridge reset. It is a power domain reset that also resets the ARM.

Table 4-7. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
MPU_RST	I	PRCM	MPU power domain reset

4.2.3.2.3 Power Management

For details, see Section 4.3.2.

4.2.4 Interrupt Controller

For information, see Chapter 12, *Interrupt Controllers*.

4.2.4.1 Clocks

Table 4-8 lists the INTC clocks.

Table 4-8. Bridge Clock Signals

Signal Name	I/O	Interface	Comments
MPU_INTC_FCLK	I	MPU clock generator	INTC functional clock

4.2.4.2 Reset

Table 4-9 lists the reset of the INTC. It is a power domain reset that also resets the whole core domain. For details, see Chapter 12, *Interrupt Controller* and Chapter 3, *Power, Reset, and Clock Management*.

Table 4-9. MPU Subsystem Reset Signal

Signal Name	I/O	Interface	Comments
CORE_RST	I	PRCM	CORE power domain reset

4.2.4.3 Power Management

See Chapter 12, *Interrupt Controller*, and Chapter 3, *Power, Reset, and Clock Management*.

4.3 MPU Subsystem Functional Description

4.3.1 Interrupts

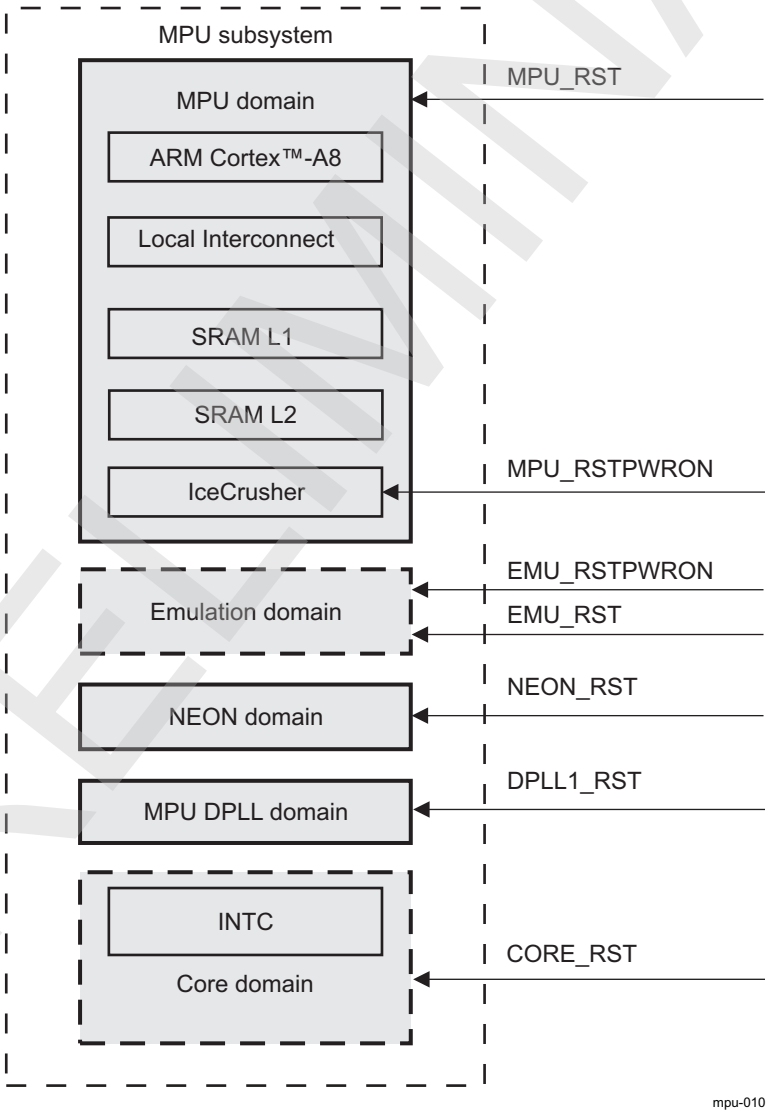
The MPU INTC is connected to the MPU through the local interconnect. It runs at half-processor speed. The INTC prioritizes all service requests from the system peripherals and generates either an IRQ or an FIQ to the MPU, depending on the INTC programming. The INTC handles only the interrupts directed to the MPU subsystem. A maximum of 96 requests can be steered/prioritized as MPU FIQ or IRQ interrupt requests. For details, see Chapter 12, *Interrupt Controller*.

4.3.2 Power Management

4.3.2.1 Power Domains

The MPU subsystem is divided into 5 power domains controlled by the PRCM, as shown in Figure 4-5. Note that the emulation domain and the core domain are not fully embedded in the MPU subsystem.

Figure 4-5. MPU Subsystem Power Domain Overview



Power management requirements at the device level govern power domains for the MPU subsystem.

The device-level power domains are directly aligned with voltage domains and, thus, can be represented as a cross reference to the different voltage domains. Table 4-10 shows the different power domains of the MPU subsystem and the modules inside.

Table 4-10. Overview of the MPU Subsystem Power Domain

Functional Power Domain	Physical Power Domain per System/Module
MPU subsystem domain	ARM, local interconnect, ARM L1 and L2 periphery logic and array, ICECrusher, ETM, APB modules
MPU NEON domain	ARM NEON accelerator
DPLL1 domain	MPU DPLL
CORE domain	MPU interrupt controller
EMU domain	EMU (ETB, DAP)

NOTE: The L1 and L2 array memories have separate control signals into the in MPU subsystem, thus, they are directly controlled by the PRCM.

For details on the physical power domains and the voltage domains, see Chapter 3, *Power, Reset, and Clock Management*.

4.3.2.2 Power States

Each power domain can be driven by the PRCM in four different states, depending on the functional mode required by the user. Table 4-11 lists the MPU power states.

Table 4-11. MPU Power States

Power State	Logic Power	Memory Power	Clocks	Memory State Retention
Active	On	On or Off	On (at least one clock)	All
Inactive	On	On or Off	Off	All
Retention	On or Off	On or Off	Off (all clocks)	All or part
Off	Off	Off	Off (all clocks)	None

The PRCM manages all transitions for each power domain by controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention. The MPU subsystem DPLL then internally synchronizes the internal clocks, resets, and switches.

4.3.2.3 Power Modes

MPU DPLL power modes:

The PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL register bit field allows putting the MPU DPLL in an autoidle mode when set to 0x1. In this mode, the MPU DPLL is automatically put into low-power stop mode when the MPU clock is no longer required. It is also restarted automatically. Table 4-12 describes the different modes that the MPU DPLL can be used in autoidle or manual mode. The manual modes (locked and low-power bypass) can be configured by the PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL register bit field. The status of the MPU DPLL clock activity can be checked with the PRCM.CM_IDLEST_PLL_MPU[0] ST_MPU_CLK bit.

Table 4-12. MPU DPLL Power Modes

Mode	System Input Clock	Clock Output	DPLL Power State	Condition
Locked	ON	ON	ON	Software request (manual) or MPU wakes up (auto)
Low power bypass	ON	ON	ON	Software request (manual) or upon global reset release (auto)
Stop low power	OFF	OFF	ON	MPU is RET or OFF (auto)
OFF	OFF	OFF	OFF	Device is OFF (auto)

The MPU DPLL power domain is switched off automatically by the PRCM only when the device enters the OFF mode.

MPU subsytem power modes:

The major part of the MPU subsystem belongs to the MPU power domain. The modules inside this power domain can be off at a time when the ARM processor is in an OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block, but initiated by the PRCM module. The MPU standby status can be checked with the PRCM.CM_IDLEST_MPU[0] ST_MPU bit.

For the MPU to be on, the core (referred here as the device core) power must be on.

The device power management does not allow INTC to go to OFF state when MPU domain is on (active or one of retention modes).

The NEON core has independent power off mode when not in use. Enabling and disabling of NEON can be controlled by software.

CAUTION

The MPU L1 cache memory does not support retention mode, and its array switch is controlled together with the MPU logic. For compliance, the L1 retention control signals exist at the PRCM boundary, but are not used. The ARM L2 can be put into retention independently of the other domains.

MPU retention modes are:

- Open switch retention (OSwR)
- Closed switch retention (CSwR)

These modes are described in Table 4-13.

Table 4-13. MPU Retention Modes

Name	Mode	ARM Logic	L1	L2
Dormant	OSwR	OFF	OFF	RET
RET	CSwR	ON	ON	RET

Table 4-14 outlines the supported operational power modes. All other combinations are illegal. The ARM L2, NEON, and ETM/Debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

Table 4-14. MPU Subsystem Operation Power Modes

Mode	MPU and ARM Core Logic	ARM L2 RAM	NEON	MPU INTC	APB/ATB Debug and ETM	Comments
1	Active	Active	Active	Active	Disabled or enabled	Functional active run mode (ETM enabled mode when emulation/debug required. Production devices should have ETM disabled).
2	Active	Active	OFF	Active	Disabled or enabled	Functional active run mode. NEON disabled via SW; NEON is internally clock gated.
3	Active	RET	Active	Active	Disabled or enabled	Do not use; see (1)
4	Active	RET	OFF	Active	Disabled or enabled	Do not use; see (1)

(1) The L2 can be put into retention mode regardless of other voltage domain states. The combination of Cortex Logic active and L2 in retention mode (modes 3 and 4) is legal, but would result in improper execution of instructions with referencing data from L2. This combination must not be used.

Table 4-14. MPU Subsystem Operation Power Modes (continued)

Mode	MPU and ARM Core Logic	ARM L2 RAM	NEON	MPU INTC	APB/ATB Debug and ETM	Comments
5	Active	OFF	Active	Active	Disabled or enabled	Active mode, L2 is off. Controlled via SW to PRCM. L2 context save and restore required or L2 flush.
6	Active	OFF	OFF	Active	Disabled or enabled	Active mode, L2 is off. Controlled via SW to PRCM. L2 context save and restore required or L2 flush.
7	OFF	RET	OFF	OFF	Disabled or enabled	Lowest power sleep mode (dormant mode), L2 is in retention. Controlled via SW to PRCM. ARM core and L1 context save and restore required or L1 flush.
8	Standby	Active	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt.
9	Standby	Active	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when NEON is off.
10	Standby	RET	Standby	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is in retention.
11	Standby	RET	OFF	Active	Disabled or enabled	Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is in retention and NEON is off.
12	Standby	OFF	Standby	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when L2 is off.
13	Standby	OFF	OFF	Active	Disabled or enabled	Standby mode. StandbyWFI controlled to put into standby and wakeup via interrupt when both L2 and NEON are off.
14	OFF	OFF	OFF	OFF	Disabled or enabled	Power-down mode

In any mode where the MPU or NEON power domains are active, the MPU DPLL clocks must be active (modes 1, 3, and 5 require active clocks from the DPLL, while Modes 7 and 8 do not).

Thus, the MPU DPLL must be in one of these states:

- Locked state
- Low power bypass state: inclk = on, clkout = on, power = on

When the MPU DPLL is not providing clocks, the MPU subsystem must be in a power mode where the MPU power domain, NEON power domain, debug power domain, and INTC power domain are in standby, retention, or off state. The states of the MPU DPLL can be:

- Locked
- STOP low power
- OFF

4.3.2.4 Transitions

Table 4-15 describes allowable transitions from power modes described in Table 4-14. For example, a transition from mode 13 to mode 4 is allowed, but the reverse is not true because the L2 RET to OFF is illegal.

Any mode change that requires state saving or flush must be serialized. For example, L2 RET does not require state saving, so it can happen at the same time as power-down NEON. L2 off and NEON off cannot happen at the same time, because L2 flush and NEON state saving must be serialized. Standby mode can enter from active mode only by executing the wait for interruption (WFI) instruction.

Table 4-15. Power Mode Allowable Transitions

	To Power Mode													
From	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**
1	Y	Y	Y	Y	Y			Y						Y
2	Y	Y	Y	Y		Y			Y		Y			Y
3	Y	Y	Y	Y			Y			Y				
4	Y	Y	Y	Y			Y				Y			
5	Y		Y	Y	Y	Y	Y			Y		Y		Y
6		Y	Y	Y	Y	Y	Y				Y		Y	Y
7	Y	Y	Y	Y			Y							
8	Y		Y					Y		Y				
9	Y	Y	Y	Y					Y		Y			
10	Y		Y					Y		Y				
11	Y	Y	Y	Y					Y		Y			
12	Y		Y		Y							Y		
13	Y	Y	Y	**Y**	Y	Y			Y		Y		Y	
14	Y	Y	Y	Y	Y	Y	Y							Y

For more information about clocks, reset, power management, and wake-up events for the MPU subsystem, see Chapter 3, *Power, Reset, and Clock Management*.

4.4 MPU Subsystem Basic Programming Model

For detailed descriptions of registers used for MPU configuration, see Chapter 3, *Power, Reset, and Clock Management*, and Chapter 12, *Interrupt Controller*.

4.4.1 MPU Subsystem Initialization Sequence

The MPU_RST signal must be asserted when the DPLL1_FCLK clock is actively toggling. This assumes that the DPLL has already been programmed and generating a clock inside the MPU subsystem. The MPU_RST signal starts the module clocks at a div/2 ratio as the DPLL1_FCLK clock and ARM at a div/1 ratio. The ARM_RST is asserted 18 ARM clock cycles after MPU_RST. The first request from ARM only emerges after this.

For more information, see Chapter 26, *Initialization*.

4.4.2 Clock Control

For clock configuration settings, see Chapter 3, *Power, Reset, and Clock Management*.

4.4.3 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for MPU power domain:

- Basic power on reset
- MPU into standby mode
- MPU out of standby mode
- MPU power on from a powered-off state

4.4.3.1 Basic Power-On Reset

The power on reset follows the following sequence of operation and applies to initial power-up and wakeup from device-off mode.

1. Reset DPLL, supply reference clock, program the MPU DPLL in applicable DPLL mode to generate clocks for MPU subsystem modules. This is controlled solely by the PRCM module.
2. Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during the MPU reset and CORE reset.

4.4.3.2 MPU Into Standby Mode

The MPU into standby mode uses the following sequence of operation and is applicable to initial power-up and wakeup from device-off mode.

1. The ARM core initiates entering into standby through software only (CP15 - WFI).
2. The MPU modules are requested internally by MPU subsystem to enter idle after ARM core standby is detected.
3. The MPU is in standby, its output asserted by PRCM (all outputs assured to be at reset values).
4. The PRCM can now request INTC to enter into idle mode. Acknowledgment from INTC goes to PRCM.
5. The PRCM can starts to shut down clocks through DPLL programming.

NOTE: The INTC SWAKEUP output is a pure hardware signal to PRCM for the status of its IDLE request and IDLE acknowledge handshake.

NOTE: In debug mode, the ICECrusher can prevent the MPU subsystem from entering into IDLE mode. See IceCrusher programming details in the emulation TRM.

4.4.3.3 MPU Out of Standby Mode

The MPU out of standby mode uses the following sequence of operation and applies to initial power-up and wakeup from device off mode.

1. The PRCM must start clocks through DPLL programming.
2. Detect active clocking through status output of DPLL
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

4.4.3.4 MPU Power-On From a Powered-Off State

1. DPLL Power On, MPU Power On, NEON Power On, Core Power On (INTC) should follow the ordered sequence per power switch daisy chain to minimize the peaking of current during power-up.

NOTE: The core domain must be on, and reset, with the clocks of the DPLL on, before the MPU can be reset.

2. Next, follow the reset sequence as described in Section 4.4.3.1, *Basic Power-On Reset*.

4.4.4 ARM Programming Model

For the complete programming model, see the *ARM Cortex-A8 Technical Reference Manual*.

IVA2.2 Subsystem

This chapter describes the image video and audio accelerator (IVA2.2) subsystem.

Topic **Page**

5.1 IVA2.2 Subsystem Overview

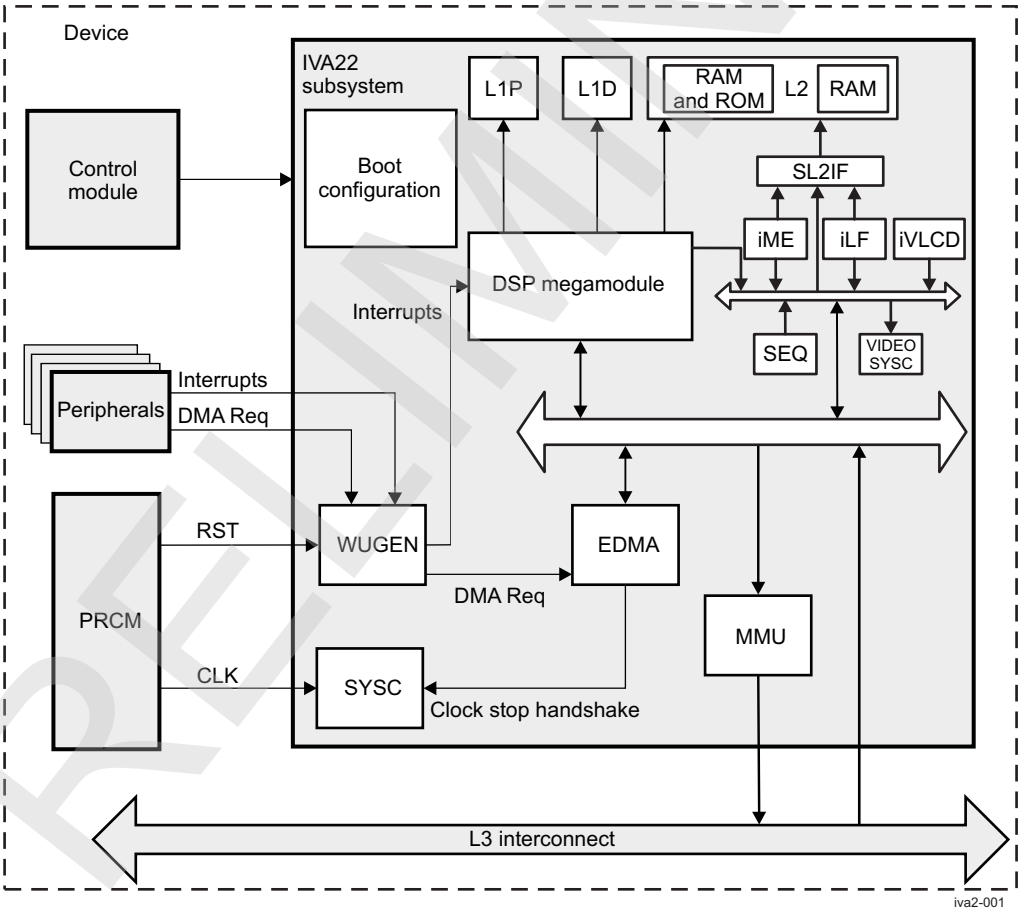
The device includes the high-performance Texas Instruments image video and audio accelerator (IVA2.2), based on the TMS320DMC64X+ VLIW digital signal processor (DSP) core.

The internal architecture is an assembly of the following components:

- High-performance TI DSP (TMS320DMC64X+) integrated in a megamodule, including local L1/L2 cache and memory controllers
- L1 RAM and L2 RAM and ROM
- Video hardware accelerator module, including local sequencer
- Dedicated enhanced data memory access (EDMA) engine to download/upload data from/to memories and peripherals external to the subchip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated modules SYSC and WUGEN in charge of power management, clock generation, and connection to the power, reset, and clock manager (PRCM) module

Figure 5-1 shows the IVA2.2 subsystem top-level architecture.

Figure 5-1. IVA2.2 Subsystem Highlight



5.1.1 IVA2.2 Subsystem Key Features

The IVA2.2 subsystem has the following main features:

- 32-bit fixed-point media processor
- VLIW architecture based on programmable enhanced version of C64x DSP core
- 8 instructions/cycle, 8 execution units:

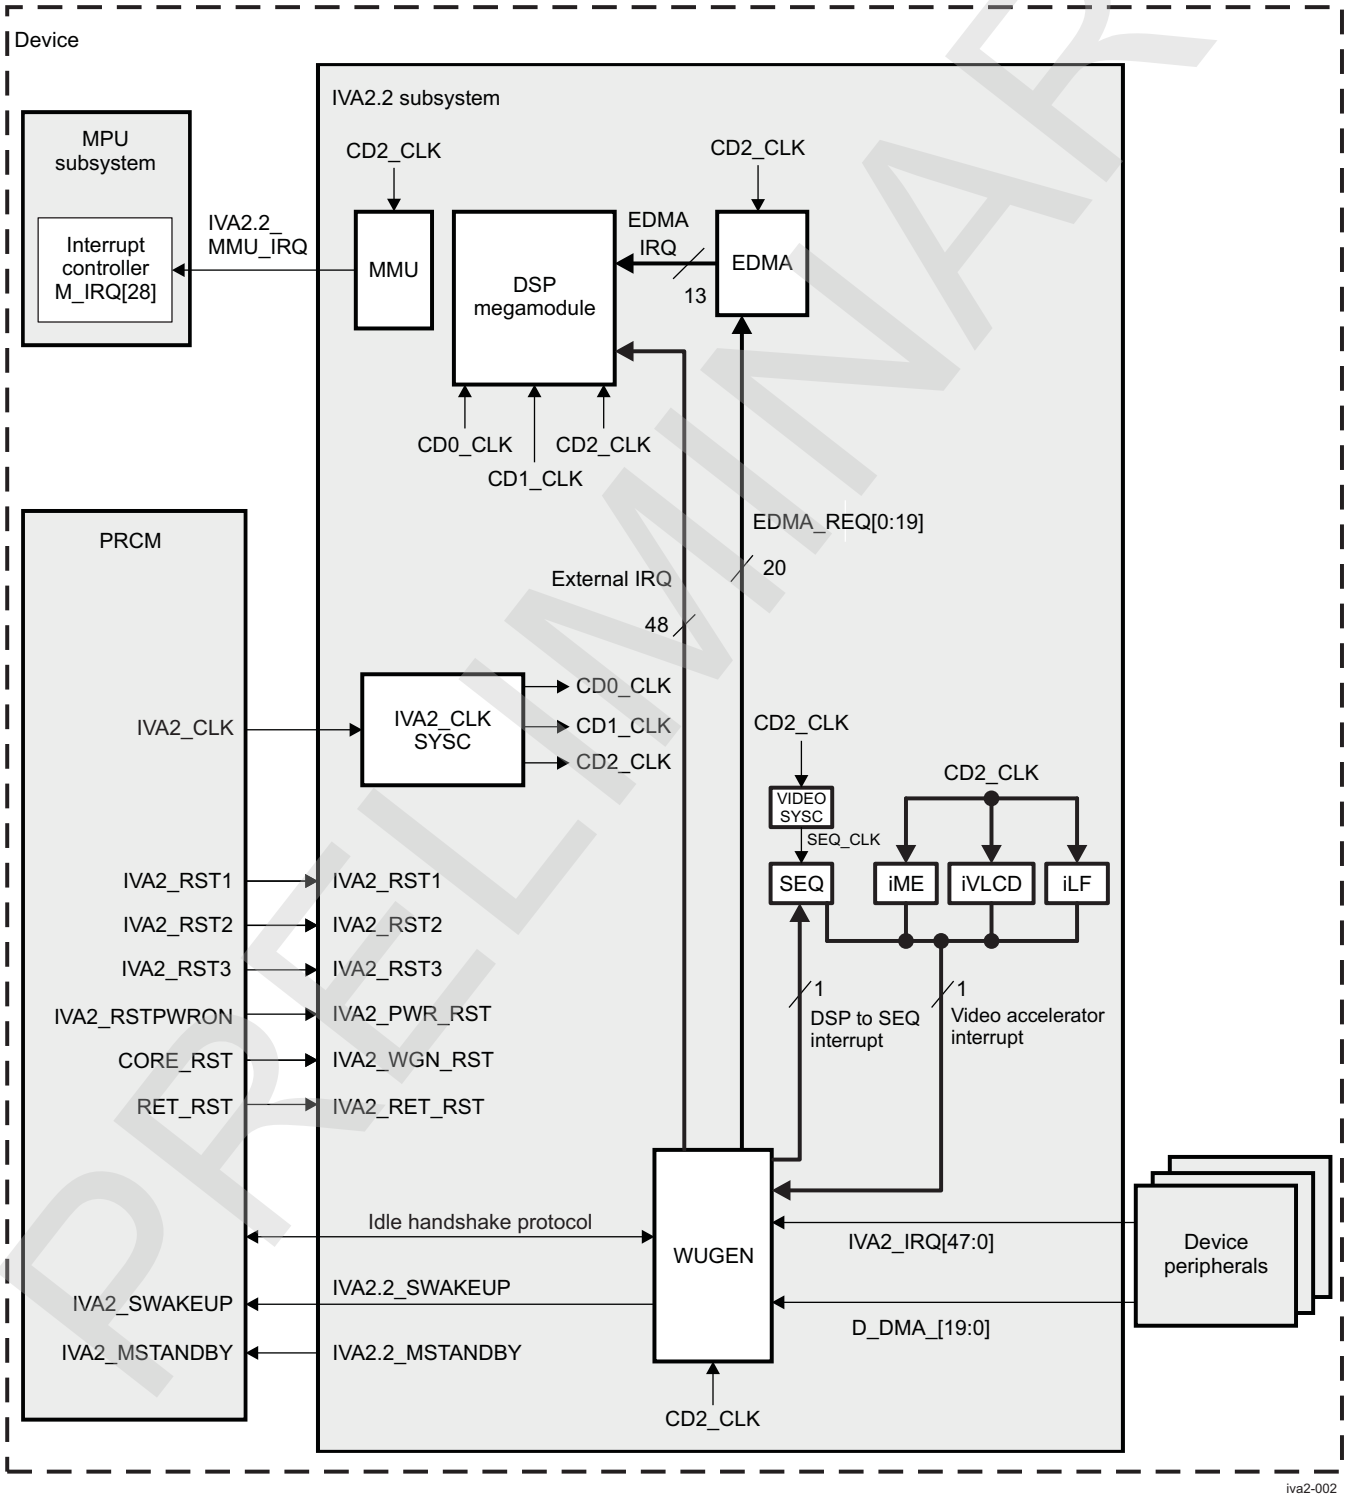
  - Optimized instruction set for video and image processing
  - Eight 8 x 8 or 16 x 16 MAC per cycle
  - Eight SAD per cycle
  - Eight interpolations (a + b + 1) >>1 per cycle
  - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megamodule:
  - Dynamically mixed 32-bit and 16-bit instruction sets
  - Software pipelined loop (SPLOOP) instruction buffer
  - Separate power domain
  - Supported multiple power-down states
- 2-level memory subsystem hierarchy:
  - L1P (program):
    - 32KB direct-mapped cache-32-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
  - L1D (data):
    - 32KB 2-way set associative cache-64-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/32KB memory, 4KB/28KB, 8KB/24KB, 16KB/16KB, or 32KB/0KB)
    - 48-KB memory-mapped SRAM
  - L2 (program and data):
    - 64KB 2-way set associative cache-128-byte cache line, configurable as cache or memory-mapped (possible values are: 0KB cache/64KB memory, 32KB/32KB, or 64KB/0KB)
    - 32-KB memory-mapped SRAM
    - 16-KB ROM
- Video hardware accelerator:
  - Improved motion estimation dedicated hardware
  - Improved loop-filtering dedicated hardware
  - Improved variable-length coder/decoder with quantizing-capabilities-dedicated hardware
  - Dedicated sequencer
  - Local interconnect
  - Shared level 2 (L2) memory interface/arbiter
- Private direct memory access (DMA) controller:
  - 128 logical channels
  - 1D/2D addressing
  - Chaining capability
  - Fully pipelined, two 64-bit read ports, two 64-bit write ports
  - Single-access 32-byte or 64-byte incrementing bursts
- Level 1 (L1) interrupt controller
- Local IVA digital phase-locked loop (DPLL) supplying IVA subsystem clocking
- 32-entry MMU for seamless integration in high-level operating system (OS) environment
- IVA2.2 system interfaces:
  - 64-bit L3 port shared for external memory accesses:
    - Multithreaded link shared by DSP core and DMA accesses
    - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between IVA2.2 and L3
    - Incrementing burst support
    - Critical line first, to reduce line-fetch latency to the processor
  - Host port interface (HPI) for MMU programming and access to IVA2.2 internal memories. Can be synchronous or asynchronous.
  - System interfaces: clocking, power management

- C-friendly environment (state-of-the-art C-compiler for VLIW architecture)
- Texas Instruments low-overhead DSP-BIOS operating system

5.2 IVA2.2 Subsystem Integration

Figure 5-2 shows IVA2.2 subsystem integration in the device.

Figure 5-2. IVA2.2 Subsystem Integration



5.2.1 Clocking, Reset, and Power-Management Scheme

5.2.1.1 Clocks

5.2.1.1.1 IVA2.2 Clocks

The IVA2.2 subsystem receives one single clock signal (IVA_CLK) from the PRCM.

NOTE: When the IVA2.2 subsystem does not require an internal clock, the internal clocks can be disabled at the PRCM level by setting the PRCM.CM_FCLKEN_IVA2 EN_IVA2 bit to 0.

From this clock (IVA_CLK), three internal clocks are generated by the IVA2.2 system control module (SYSC):

- CD0_CLK: Fastest IVA2.2 subsystem functional clock, dedicated to the DSP. Its frequency can be adjusted at the PRCM level by setting the PRCM.CM_CLKSEL1_PLL_IVA2 and PRCM.CM_CLKSEL2_PLL_IVA2 registers.
- CD1_CLK: Divide-by-two of the CD0_CLK clock
- CD2_CLK: Divide-by-two of the CD0_CLK clock

Generation of these three clocks is handled internally to the IVA2.2 subsystem by the SYSC module under direct control of the PRCM.

Table 5-1 lists the clock domains in the IVA2.2 subsystem and shows the roles of the clocks.

Table 5-1. IVA2.2 Internal Clock

CD0	CD0_CLK	DSP core + PMC + DMC
CD1	CD1_CLK	UMC + power-down + interrupt controller
CD2	CD2_CLK	EMC + IDMA + DSP megamodule external interfaces + local interconnect + EDMA + MMU + SYSC + iVLCD + iME + iLF

NOTE: The internal clocks can be shut down by the PRCM module after the handshake protocol is complete. To configure the PRCM so that internal clocks are hardware-supervised, set the PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL field to 0x1. For more information, see Chapter 3, *Power, Reset, and Clock Management*.

The video sequencer module receives SEQ_CLK from CD2_CLK. This divided clock is generated in the video accelerator/sequencer system configuration. For more information about the divided clock of the sequencer, see Section 5.4.10.1, *Clock Management*.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not apply to production.

5.2.1.2 Resets

5.2.1.2.1 Hardware Resets

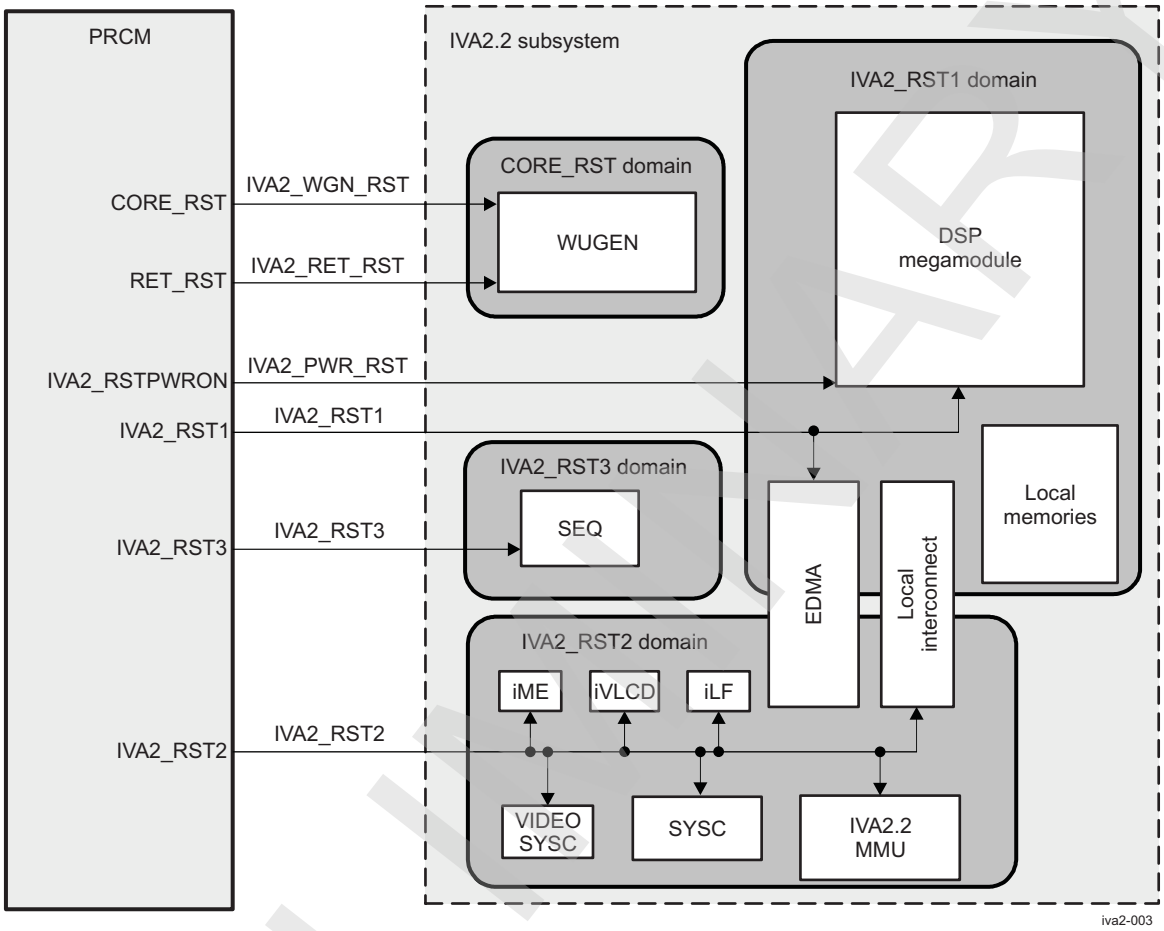
Figure 5-3 shows the seven hardware input reset signals at the boundary of the IVA2.2 subsystem:

- IVA2_RST1, connected to the DSP megamodule and EDMA modules
- IVA2_RST2, connected to the SYSC, MMU, improved variable-length coder/decoder (iVLCD), iME, iLF, and local interconnect
- IVA2_RST3, connected to the sequencer
- CORE_RST, connected to the IVA2.2 subsystem wake-up generator (WUGEN) module
- RET_RST, connected to the subsystem WUGEN retention logic to reset registers that keep their value

across a warm reset sequence

- IVA2_RSTPWRON, which performs a power-on initialization of IVA2.2 logic

Figure 5-3. IVA2.2 Subsystem Resets



After chip power on, the IVA2.2 subsystem is kept under reset and only the RET_RST is released from reset. Then, only the WUGEN is released from reset as part of the core domain. The IVA2.2 remains under reset until the microprocessor unit (MPU) clears the PRCM.RM_RSTCTRL_IVA2[1] RST2_IVA2 bit. On this action, the PRCM switches on the IVA2.2 power domain, sets the clocks back, and releases the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2_RST2 reset. At this stage, the DSP megamodule is kept under reset (unless the MPU also cleared the PRCM.RM_RSTCTRL_IVA2[0] RST1_IVA2 bit); the MPU can upload some code and data in the C64x+ memory. When the MPU has uploaded the code in the C64x+ memory, the MPU clears the RST1_IVA2 bit, releasing the DSP megamodule from reset. At this point, the sequencer is kept under reset (unless the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit was cleared); the DSP can upload some code and data in the sequencer memory. When the DSP has uploaded the coded in the sequencer memory, the DSP clears the RST3_IVA2 bit, releasing the sequencer from reset.

The MPU can apply a software reset to the IVA2.2. For a software reset to be safe, the IVA2.2 must be in clock-off mode (DSP in idle mode with clocks shut down by the PRCM; for information about the clock-off state transition, see Section 5.4.10.3 , *Power-Down and Wake-Up Management*.) For instance, the MPU can use a mailbox interrupt to ask the IVA2.2 to go to IDLE state. In that case, only IVA2_RST1 and/or IVA2_RST2 and/or IVA2_RST3 are applied, depending on which bits are set, and CORE_RST and IVA2_RSTPWRON are never applied.

The IVA2.2 can also program the PRCM to go to OFF state automatically when the IVA2.2 is idle. Then, in response to a wake-up event (for example, an interrupt), the PRCM can switch on the IVA2.2 power domain, set the clocks back, and release the power-on reset. When the IVA2.2 power-on sequence completes (hardware handshake), the PRCM releases the IVA2_RST3, IVA2_RST2, and IVA2_RST1 resets (RST1, RST2, and RST3 SW bits are assumed to be clear). However, for the IDLE instruction (to transition to OFF state) to be executed, the user must program the PRCM to prevent the sequencer (IVA2_RST3) from being released from reset after a wakeup of the IVA2 from POWER OFF state. CORE_RST can be applied only if the device is coming out of CHIP OFF state (CORE power domain also in OFF state). In this case, CORE_RST is released at the same time as the IVA power-on reset.

For some detected severe issues or if the user applies an external system reset, the IVA2.2 can receive a warm reset. IVA2_RST1, IVA2_RST2, IVA2_RST3, DPLL_RST, RET_RST, and CORE_RST are applied. When the warm reset source is released, IVA2_RST1, IVA2_RST2, IVA2_RST3, and CORE_RST are released. Power-on reset is not applied in this case.

5.2.1.2.2 Software Resets

IVA2.2 subsystem reset signals are sourced from the PRCM module. Some modules of the DSP subsystem can also be reset by software control.

The IVA2_RST1 signal maps to the PRCM.RM_RSTCTL_IVA2 RST1_IVA2 bit, the IVA2_RST2 signal maps to the PRCM.RM_RSTCTL_IVA2 RST2_IVA2 bit, and the IVA2_RST3 signal maps to the PRCM.RM_RSTCTL_IVA2 RST3_IVA2 bit in the PRCM register RM_RSTCTRL_IVA2. Writing these three bit fields lets the software reset the IVA2.2 subsystem.

NOTE: Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

The WUGEN reset signal (CORE_RST) is reset with the CORE power domain, which is reset at the occurrence of either global cold or global warm reset events. For more information about global reset sources, see Chapter 3, *Power, Reset, and Clock Management*.

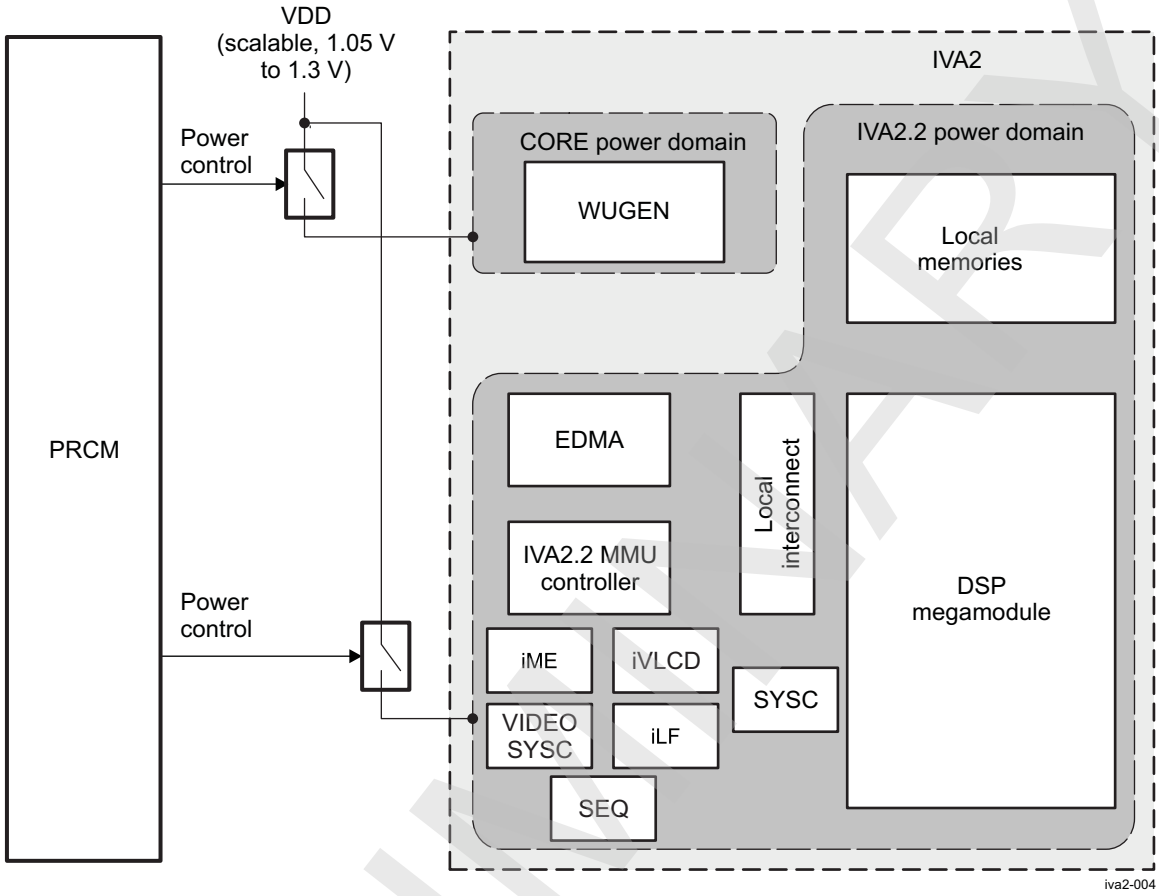
For more information about software resets, see Section 5.4.10.2, *Reset Management*.

5.2.1.3 Power Domain

The IVA2.2 subsystem comprises three power domains that can be shared with other subsystems at the chip level (see Figure 5-4):

- DSP power domain: Everything specified in the IVA2.2 subsystem, except the wake-up generator
- CORE power domain: Includes the WUGEN

Figure 5-4. IVA2.2 Power Domain



The DSP power domain can be powered off if the CORE power domain is powered on. The PRCM ensures that the DSP power domain is always powered off when the CORE power domain is powered off.

The CORE power domain includes several other system-level components of the device. The WUGEN module is included in the CORE power domain to enable the powered-off DSP subsystem to be awakened after receiving an interrupt, a DMA request, or an L3 slave port access.

Memory voltage can be reduced locally when memory is not being used, to reduce memory leakage:

- If IVA2.2 is not active, this is controlled by the PRCM.PM_PWSTCTRL_IVA2 register by setting the MEMONSTATE and/or MEMRETSTATE bit fields.

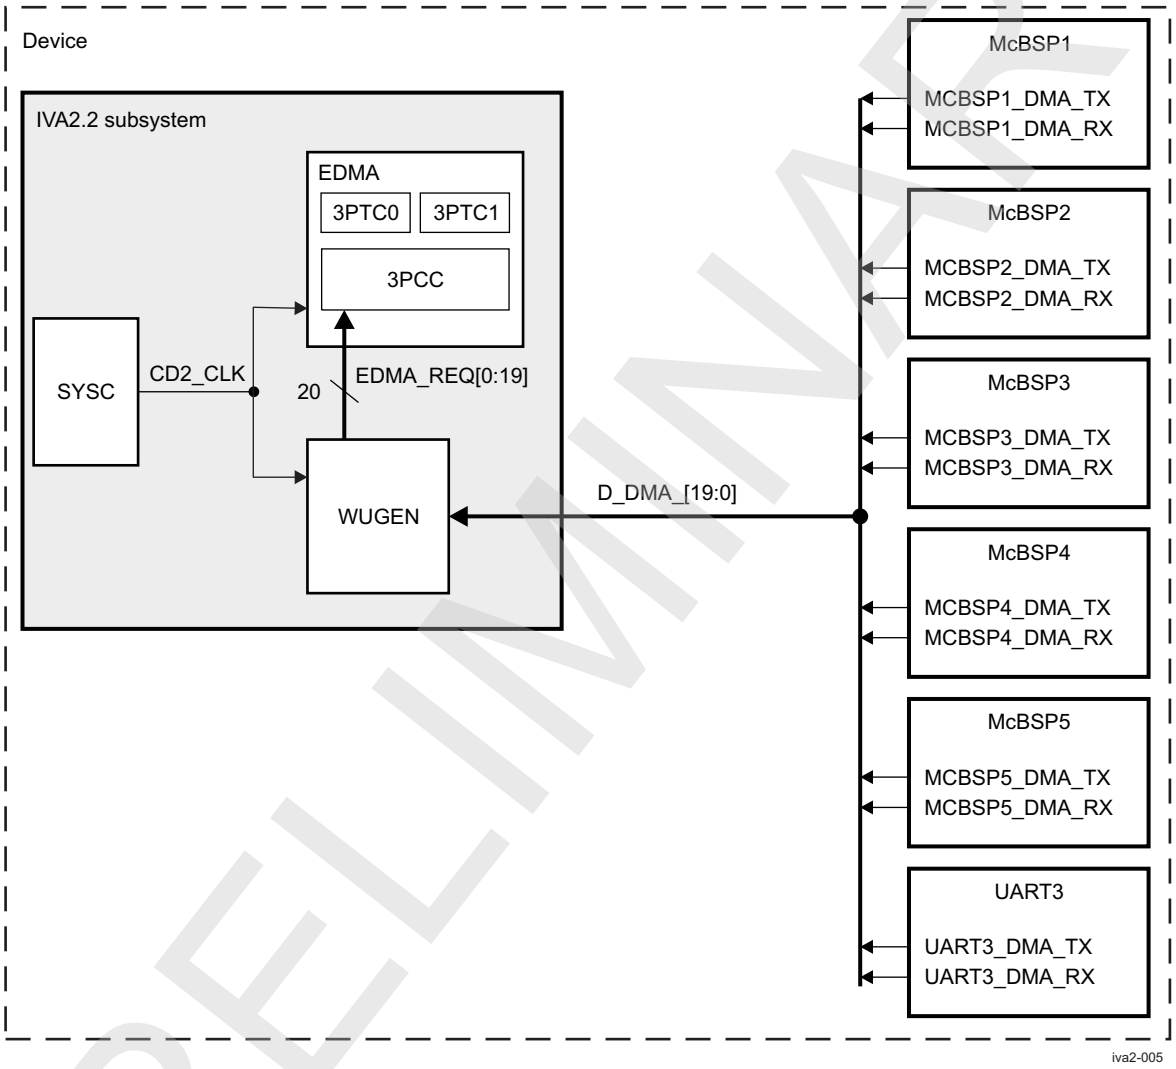
For a detailed description of power domains and controls in the device, see Chapter 3, *Power, Reset, and Clock Management*.

5.2.2 Hardware Requests

5.2.2.1 DMA Requests

The IVA2.2 subsystem receives 14 DMA requests from specific peripherals, such as the McBSP module and the UART module (see Figure 5-5).

Figure 5-5. IVA2.2 EDMA Requests



For a description of the EDMA controller, see Section 5.3.2.1, *EDMA*.

Table 5-2 lists EDMA request mappings to the IVA2.2 subsystem EDMA controller.

Table 5-2. IVA2.2 Subsystem EDMA Request Mappings

DMA	Source	Description
D_DMA_0	MCBSP1_DMA_TX	MCBSP module 1 - transmit request
D_DMA_1	MCBSP1_DMA_RX	MCBSP module 1 - receive request
D_DMA_2	MCBSP2_DMA_TX	MCBSP module 2 - transmit request
D_DMA_3	MCBSP2_DMA_RX	MCBSP module 2 - receive request
D_DMA_4	MCBSP3_DMA_TX	MCBSP module 3 - transmit request
D_DMA_5	MCBSP3_DMA_RX	MCBSP module 3 - receive request
D_DMA_6	MCBSP4_DMA_TX	MCBSP module 4 - transmit request

Table 5-2. IVA2.2 Subsystem EDMA Request Mappings (continued)

DMA	Source	Description
D_DMA_7	MCBSP4_DMA_RX	MCBSP module 4 - receive request
D_DMA_8	MCBSP5_DMA_TX	MCBSP module 5 - transmit request
D_DMA_9	MCBSP5_DMA_RX	MCBSP module 5 - receive request
D_DMA_10	UART3_DMA_TX	UART module 3 - transmit request
D_DMA_11	UART3_DMA_RX	UART module 3 - receive request
D_DMA_12	Reserved	
D_DMA_13	Reserved	
D_DMA_14	Reserved	
D_DMA_15	Reserved	
D_DMA_16	Reserved	
D_DMA_17	Reserved	
D_DMA_18	Reserved	
D_DMA_19	Reserved	

NOTE: All EDMA requests are shared DMA requests; they are also mapped on the system DMA (sDMA). For more information, see Chapter 11, *DMA*.

For more information about EDMA request management, see Section 5.4.4.3, *Programming an EDMA Transfer*.

5.2.2.2 Interrupt Requests

The IVA2.2 subsystem manages three types of interrupts (see Figure 5-6):

- Internal interrupts: Requests generated by modules in the IVA2.2 subsystem or in the DSP megamodule included in the IVA2.2 subsystem
- External interrupts: Requests generated by peripherals external to the IVA2.2 subsystem, like SPI, display subsystem, or camera subsystem. Peripherals that generate interrupts at the IVA2.2 level use the IVA2_IRQ[47:0] input lines of the IVA2.2 subsystem.
- MMU interrupt: The IVA2.2 MMU can generate an interrupt to an external host outside the IVA2.2 subsystem. As shown in Figure 5-2, the interrupt line of the MMU, IVA2_MMU_IRQ, is connected to M_IRQ_28 of the MPU subsystem interrupt controller.

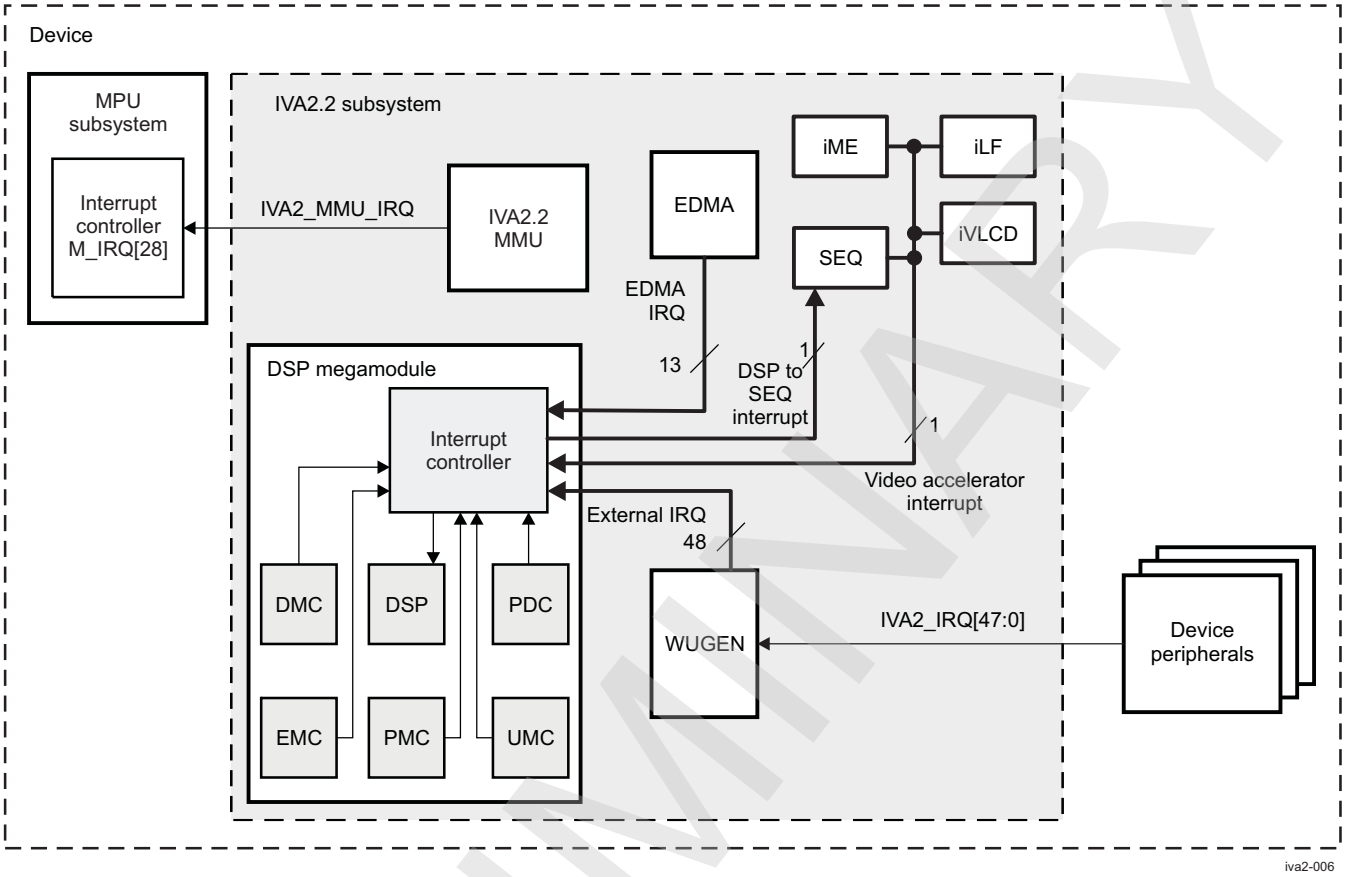
For more information about the functionality of the IVA2.2 MMU, see Section 5.3, *IVA2.2 Subsystem Functional Description*.

To manage and expand the interrupt capabilities of the DSP megamodule (internal and external interrupt requests), the IVA2.2 subsystem includes two levels of interrupt control (see Figure 5-6):

- One interrupt controller (INTC), integrated in the DSP megamodule. This module controls all interrupt requests (internal and external) except the MMU interrupt.

  For more information about the INTC, see Section 5.3.1.7.
- One WUGEN: Responsible at the IVA2.2 subsystem level for detecting wake-up events (interrupts, DMA requests, and slave port access) when the IVA2.2 is powered down. The WUGEN also handles formatting interrupts from device peripherals to the DSP megamodule INTC.

Figure 5-6. IVA2.2 Interrupt Management



In addition to interrupt sources internal to the IVA2.2 subsystem, several interrupt sources coming from device peripherals are connected to the DSP megamodule INTC, but not directly.

These external interrupt sources are first resynchronized in the WUGEN module, synchronously with the CD2 clock domain clock (CD2_CLK). Then the resynchronized versions are connected to the INTC.

Table 5-3 lists the global interrupt mappings of the IVA2.2 subsystem.

Table 5-3. IVA2.2 Interrupt Mappings

EVT	Interrupts/Events	IVA2.2 Pin Name	Interrupt Source	Interrupt Description
0	EVT0	N/A (internal)	DSP INT CTL	Output of event combiner 0, for events 4-31
1	EVT1	N/A (internal)	DSP INT CTL	Output of event combiner 1, for events 32-63
2	EVT2	N/A (internal)	DSP INT CTL	Output of event combiner 2, for events 64-95
3	EVT3	N/A (internal)	DSP INT CTL	Output of event combiner 3, for events 96-127
4-8	Reserved	N/A (internal)	N/A	N/A
9	EMU_DTDMA	N/A (internal)	DSP ECM	ECM interrupt (host scan access, DTDMA)
10	Reserved	N/A (internal)	N/A	N/A
11	EMU_RTDXRX	N/A (internal)	DSP RTDX	RTDX receive complete
12	EMU_RTDXTX	N/A (internal)	DSP RTDX	RTDX transmit complete
13	IDMAINT0	N/A (internal)	DSP IDMA	Internal DMA (IDMA) channel 0 interrupt
14	IDMAINT1	N/A (internal)	DSP IDMA	IDMA channel 1 interrupt
15-27	Reserved	N/A (internal)	N/A	N/A
28	CCMPINT	N/A (internal)	EDMA TPCC	TPCC memory protection interrupt
29	CCINTG	N/A (internal)	EDMA TPCC	TPCC global interrupt

Table 5-3. IVA2.2 Interrupt Mappings (continued)

EVT	Interrupts/Events	IVA2.2 Pin Name	Interrupt Source	Interrupt Description
30	CCINT3	N/A (internal)	EDMA TPCC	TPCC region 3 interrupt
31	CCINT4	N/A (internal)	EDMA TPCC	TPCC region 4 interrupt
32	CCINT5	N/A (internal)	EDMA TPCC	TPCC region 5 interrupt
33	CCINT6	N/A (internal)	EDMA TPCC	TPCC region 6 interrupt
34	CCINT7	N/A (internal)	EDMA TPCC	TPCC region 7 interrupt
35	CCINT8	N/A (internal)	EDMA TPCC	TPCC region 8 interrupt
36	CCINT1	N/A (internal)	EDMA TPCC	TPCC region 1 interrupt
37	CCINT2	N/A (internal)	EDMA TPCC	TPCC region 2 interrupt
38	CCERRINT	N/A (internal)	EDMA TPCC	TPCC error interrupt
39	TCERRINT0	N/A (internal)	EDMA TPTC0	TPTC0 error interrupt
40	TCERRINT1	N/A (internal)	EDMA TPTC1	TPTC1 error interrupt
41-44	Reserved	N/A (internal)	N/A	N/A
45-50	Reserved	IVA2_IRQ[0-5]	N/A	Reserved
51	GPT5_IRQ	IVA2_IRQ[6]	GPTIMER5	General-purpose timer module 5
52	GPT6_IRQ	IVA2_IRQ[7]	GPTIMER6	General-purpose timer module 6
53	GPT7_IRQ	IVA2_IRQ[8]	GPTIMER7	General-purpose timer module 7

(1) EVT94 is used by the DSP to generate an interrupt to the sequencer by means of the HOST_MBX in the SEQ_IRQSTATE register.

The interrupts generated by the WUGEN module (interrupts from device peripherals) are programmable using a set of registers accessible by the user.

Events related to these external interrupts can be masked by writing to the IVA2.WUGEN_MEVTSET0 or IVA2.WUGEN_MEVTSET1 registers. The interrupts can also be individually unmasked by using the IVA2.WUGEN_MEVTCLR0 or IVA2.WUGEN_MEVTCLR1 registers. By default (after power on), these external interrupts are masked in WUGEN.

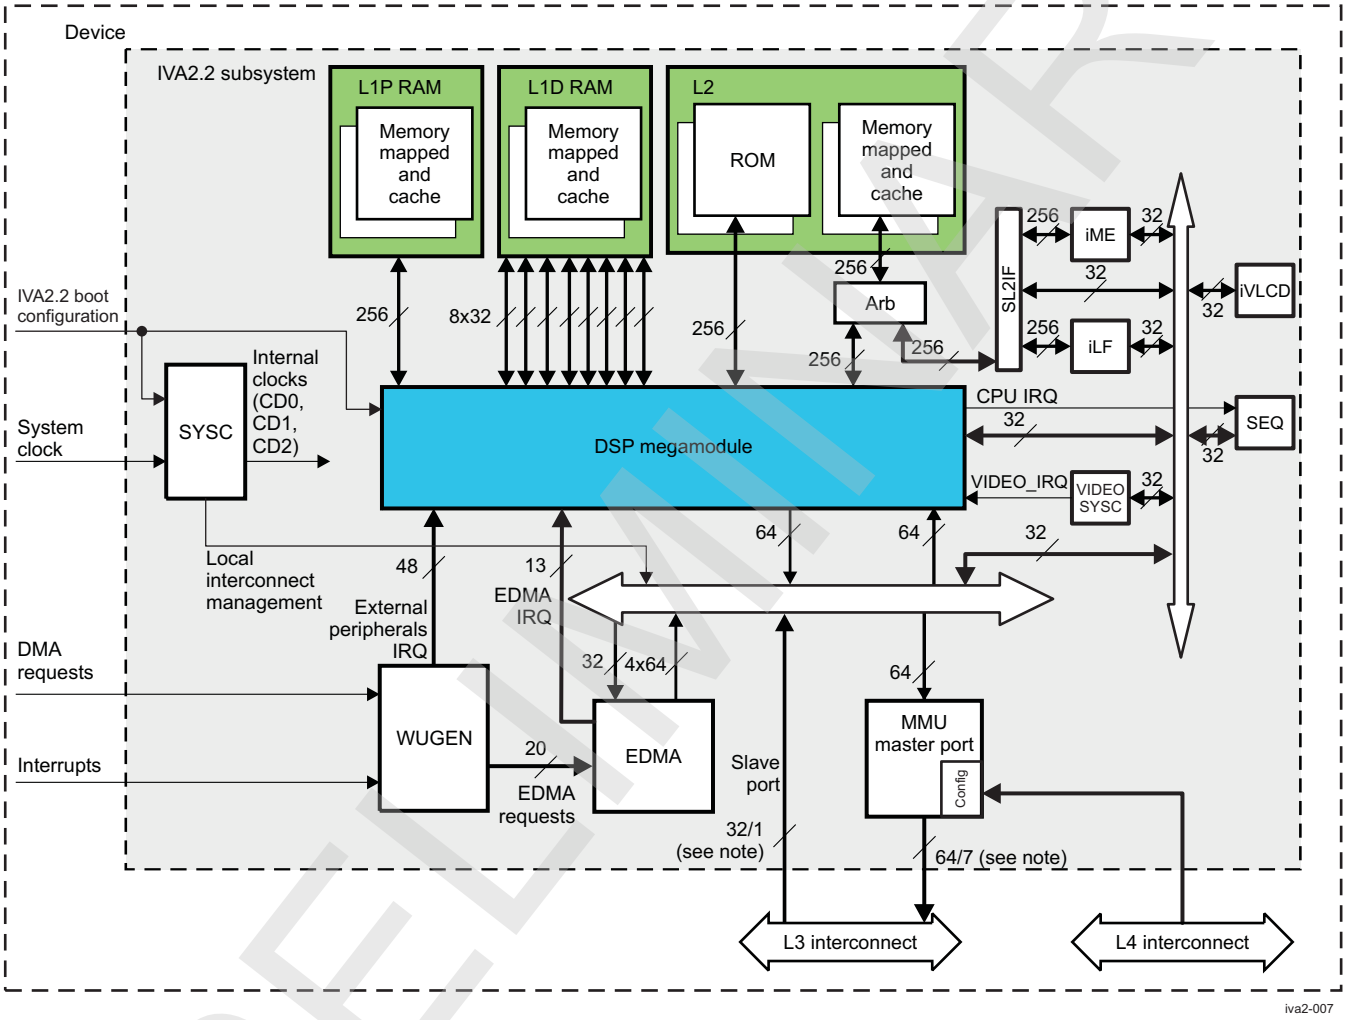
All other interrupts are directly managed by the IVA2.2 DSP INTC, and the DSP registers are set. For information about the DSP INTC, see the documents listed in Section 5.3.1.8, *Other DSP Reference Documents*.

5.3 IVA2.2 Subsystem Functional Description

The IVA2.2 subsystem is composed of a DSP megamodule coupled with several submodules that enable its integration in the device architecture. The IVA2.2 subsystem provides one slave port and one master port; both ports are connected to the L3 interconnect.

Figure 5-7 is a block diagram of the IVA2.2 subsystem.

Figure 5-7. IVA2.2 Subsystem Block Diagram



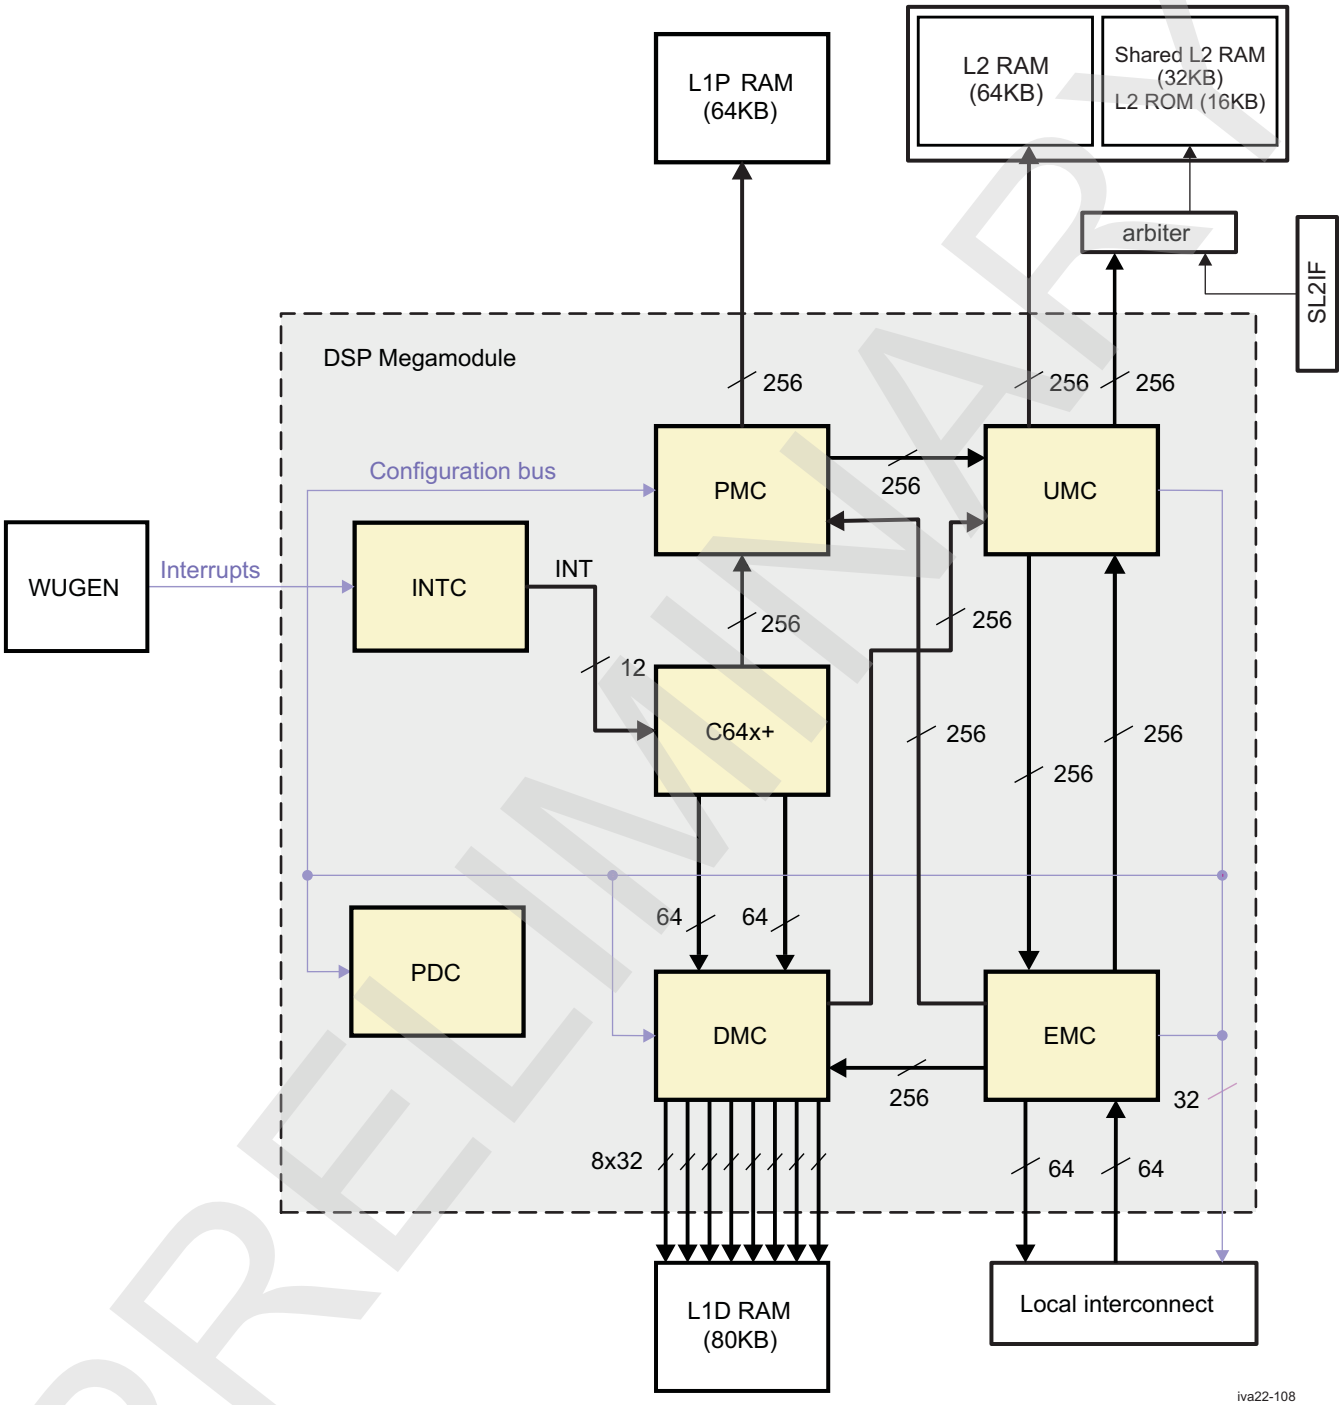
NOTE: This indicates the number of threads for IVA2.2 master/slave port interrupts. For details, see Chapter 9, *Interconnect*.

5.3.1 DSP Megamodule

The C64x+ DSP megamodule is a class of derivative sections of the generalized embedded megamodule. DSP megamodule is a hardware-configurable megamodule module that comprises a version of the C64x+, an L1 program memory controller (PMC), an L1 data memory controller (DMC), a unified memory controller (UMC), an extended memory controller (EMC), an INTC, and a power-down controller (PDC).

Figure 5-8 is a block diagram of the DSP megamodule.

Figure 5-8. DSP Megamodule Block Diagram



5.3.1.1 DSP Overview

The C64x+ is an extension of the first C64x DSP section (also named Kelvin).

The C64x features the following:

- 32-bit fixed-point media processor
- VLIW architecture
- 8 instructions/cycle, 8 execution units

- Optimized instruction set for video and image processing
- Eight 8 x 8 or 16 x 16 MAC per cycle
- Eight SAD per cycle
- Eight interpolations (a + b + 1) >>1 per cycle
- Two (32-bit x 32-bit > 64-bit) multiply operations per cycle

In addition to existing C64x features, the C64x+ includes the following:

- SPLOOP
- Compact instructions
- Extended function support
- Exception handling
- Privilege mode support
- HLOS time-stamp counter register

C64x+ operates to up to 365 MHz in the context of IVA2.2.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

For information about C64x+ DSP, see the C64x+ reference manual (Section 5.3.1.8).

5.3.1.2 Program Memory Controller Overview

The PMC is the DSP megamodule component that delivers program fetch packets when they are requested by the DSP.

The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- 32KB 0-wait state least-significant bit (LSB)-banked SRAM
- L1 program cache controller - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode support

In the IVA2.2 subsystem, the PMC controls the 32-KB SRAM typically used as cache RAM. However, the allocation of SRAM can be software-configured to keep a section of the memory as memory-mapped SRAM.

For more information, see Section 5.4.9, *Memory Management*.

5.3.1.3 DMC Overview

The DMC is the DSP megamodule component that reads or writes data from/to local memories, as requested by the DSP.

The DMC supports the following features:

- Two 64-bit memory accesses per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty.
- 80KB 0-wait state LSB-banked SRAM
- L1 data cache controller (capabilities listed in Table 5-13) - 32KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM

- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Hardware coherence maintenance with L2 (snooping)
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode support
- Per-page memory-protection attribute check support

The DMC operates to up to 365 MHz in the context of the IVA2.2. The DMC always operates at the same frequency as the DSP.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

5.3.1.4 UMC Overview

The UMC is the DSP megamodule component that reads or writes program and data from/to memory, as requested by the DMC and/or the PMC.

The UMC supports the following features:

- 64KB low-latency state SRAM (first port)
- 32KB low-latency state memory-mapped only SRAM (second port)
- 16KB low-latency ROM (second port)
- L2 unified cache controller (capabilities listed in Table 5-14) - 64KB maximum
- Software-programmable allocation of SRAM to cache or memory-mapped SRAM
- DMA transfer from/to SRAM and from ROM
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass modes support
- Per-page memory protection attribute check support
- Emulation support
- Long-distance access support (noncacheable data accesses)
- Page-based memory automatic power-down (to clock-off state) and wake-up support

The UMC contains the interfaces to L2 memory, the L1D, the L1P, and the EMC. The EMC houses the interfaces to the EDMA and internal data memory access (IDMA) engines, and thus allows the UMC and ultimately the CPU to communicate with peripherals and external memory.

The UMC has two L2 memory ports, each of which is 256 bits wide. Although accesses to the two ports are initiated serially for each requestor, only one new access is initiated per UMC clock cycle, to avoid memory-bank conflicts between the ports.

The UMC has three requestor ports: the PMC, the DMC, and the EMC. Peripheral configuration and DMA/IDMA interfacing are handled by the EMC. The PMC interface to the UMC consists of a 256-bit read-only path (L1P fetch only). The DMC and the EMC interface to the UMC, and each has separate 256-bit read and write paths of its own.

The UMC operates to up to 182.5 MHz in the context of the IVA2.2. The UMC always operates at half the frequency of the DSP.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

5.3.1.5 EMC Overview

The EMC is the megamodule component that reads or writes program and data external memory and configuration registers, as requested by the UMC.

The EMC supports the following features:

- IDMA
- 64-bit slave port for accesses from an external DMA engine and/or host to L1 or L2 memory
- 64-bit master port to serve accesses from the UMC to external memory or configuration registers

The EMC operates to up to 182.5 MHz in the context the of the IVA2.2. The EMC can operate at half or one third the frequency of the DSP.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies might not apply to production.

5.3.1.6 Memory Protection Overview

The DSP megamodule memory protection architecture divides the memory map into pages. Each page has an associated set of permissions.

Memory protection provides many benefits to a system:

- Protects operating system data structures from poorly behaving code
- Helps in debugging by providing information about illegal memory accesses
- Prevents unauthorized access to sensitive data
- Allows the OS to enforce clearly defined boundaries between supervisor and user mode accesses, leading to greater system robustness

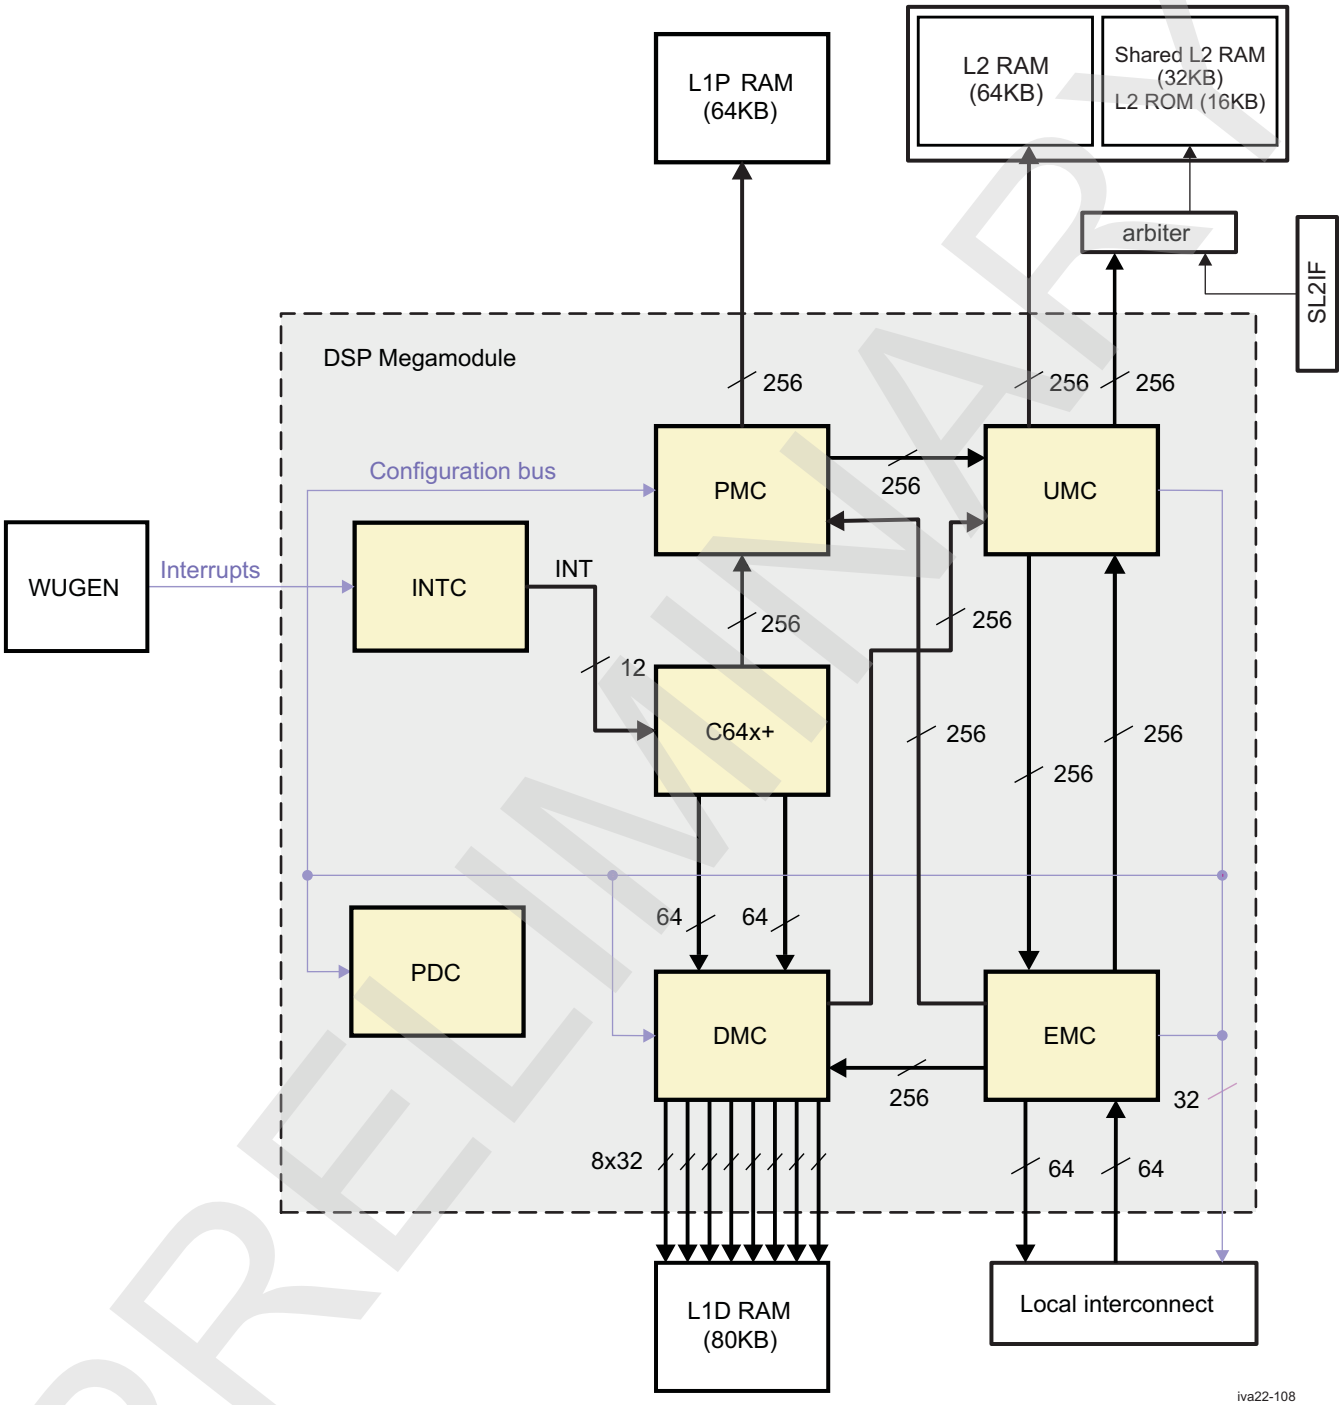
Memory protection is implemented for the PMC, DMC, UMC, and EMC, and also for the IDMA and EDMA modules.

5.3.1.7 INTC

The DSP megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines. Table 5-5 lists the global interrupt mappings of the IVA2.2 subsystem (internal and external interrupts).

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, an exception combiner, and an event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU (see Figure 5-9).

Figure 5-9. DSP Megamodule INTC Block Diagram



NOTE: Not all of the 128 event inputs of the INTC are connected to an internal or external event line. Table 5-3 lists the global interrupt mapping of the DSP INTC. Some interrupts at the IVA2.2 boundary are reserved for future use or are not used by the IVA2.2 subsystem. For information about the DSP core INTC, see the C64x+ DSP documents listed in Section 5.3.1.8, *Other DSP Reference Documents*.

5.3.1.7.1 Event Type

The interrupt controller provides three types of interrupt sources to the DSP CPU:

- Single event
  - A single system event can be directly routed to a CPU interrupt input.
  - A dropped system event is supported through the CPU dropped interrupt reporting mechanism; that is, if the CPU misses the interrupt input, the system event is missed.
- Combined event
  - Up to four event combiners
  - Each combiner allows up to 32 system events to be logically ORed into a single event that can be routed to the DSP CPU.
- Exception event: This event is considered a single event, but it is directly connected to the exception input of the DSP CPU.

5.3.1.7.2 Event Behavior

- Single event source: The interrupt selector routes 1 of 124 events to a DSP CPU interrupt, as programmed in the interrupt selector registers (IC.INTMUXj registers (where j is 1 to 3). Logic in the CPU and the INTC combine to detect instances where an interrupt request is asserted before an earlier interrupt request was serviced. The INTC records the interrupt number of the first interrupt and keeps this information until directed to release the interrupt, either through reset or by application software. This record can be used as an additional system event to notify the application of an interrupt failure. Interrupts that qualify for dropped detection are defined through an IDROP mask that sets the IC.INTDMASK register. The masked IDROP event output (EVT96; see Table 5-3) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.
- Combined source: The event combiners create a combined event from the logical OR of 32 system-event flags qualified by a mask provided through programmable registers (IC.EVTMASKi where i = 0 to 3). The combination of the event flags creates an event that is asserted when any of the event flags included in its generation is active. Software must clear the event flags (IC.EVTCLRi where i = 0 to 3) to deassert a combined event.

NOTE: The use of event flags makes it impossible for the CPU to detect the dropping of independent system events; therefore, dropped interrupt capability is not directly supported for combined events.

The interrupt event combiners create four shared interrupt sources:

- EVT0: Logical OR of EVTFLAGi[31:04] (i = 0) masked by EVTMASKi[31:04] (i = 0)
- EVT1: Logical OR of EVTFLAGi[63:32] (i = 1) masked by EVTMASKi[63:32] (i = 1)
- EVT2: Logical OR of EVTFLAGi[95:64] (i = 2) masked by EVTMASKi[95:64] (i = 2)
- EVT3: Logical OR of EVTFLAGi[127:96] (i = 3) masked by EVTMASKi[127:96] (i = 3)

EVTFLAGi are the event flag registers and EVTMASKi are the event mask registers. These combined events are presented to the interrupt selection logic.

- Exception event source: As with the event combiner, the exception combiner allows multiple system events to be grouped as a single event input to the CPU, and the combiner provides mask registers to remove undesirable events. Because only one exception is input to the CPU, all mask registers work together to combine up to 128 events as a single EXCEP output. This lets the CPU service all available system exceptions.

  The shared exception source is created as follows:

  EXCEP: Logical OR of EF[127:04] masked by XM[127:04]

  Where EF[i * 32 + j] = EVTFLAGi[j] and XM[i * 32 + j] = EXPMASKi[j] (i = 0, 1, 2, 3 and j = 0 to 31).

The logic is similar to that of the event combiners, except that only one combined event is routed to EXCEP.

5.3.1.7.3 Event Detection

The INTC contains a set of status and control registers to manage the status of system events received by the controller. These include set, flag, and clear registers covering all 128 system events. Enabling of the events is managed in the CPU for direct mapped interrupts, in the event combiner for combined events, and in the exception combiner for system exceptions. Events to the interrupt controller can be enabled/disabled only at the event source.

The event flag registers (IC.EVTFLAGi where i = 0 to 3) capture every system event received, regardless of its destination: event combiner, exception combiner, or interrupt selector. Events that are not masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAGi (where i = 0 to 3) register corresponding to the event, and are used to determine when the combined event is generated. Events that are masked by either the event combiner or the exception combiner are captured in the IC.EVTFLAGi register, but do not affect when the DSP CPU interrupt is generated.

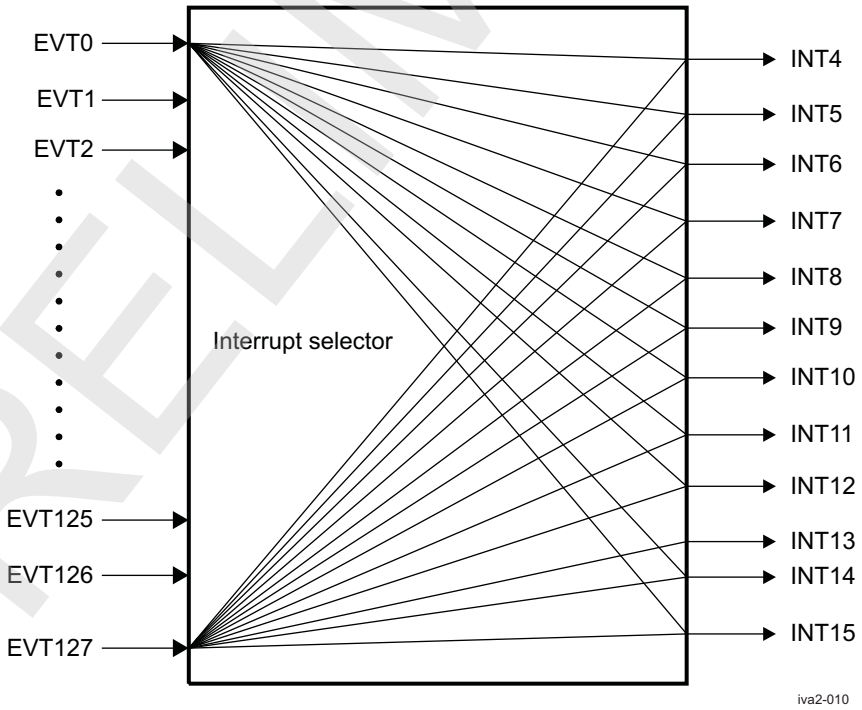
The event flags in the IC.EVTFLAGi registers retain the value of 1 for any event received. These registers are read-only and must be cleared through the write-only IC.EVTCLRi registers. The IC.EVTSETi registers can be used to manually set bits in the IC.EVTFLAGi registers, including those that are masked.

NOTE: Because external events are maintained by the peripheral until they are explicitly cleared by software, drop event detection does not work for external events (interrupts from peripherals external to the IVA2.2 subsystem).

5.3.1.7.4 Event Selection

The DSP CPU has 12 available maskable interrupts. The interrupt selector allows any of the 128 system events, either from the event inputs or from the event combiners, to be routed to any of the 12 CPU interrupt inputs (see Figure 5-10).

Figure 5-10. Interrupt Selector Block Diagram



The user can choose which of the 128 input events is mapped to each of the 12 CPU interrupts by writing the event number in the bit field corresponding to the CPU interrupt in the INTMUXj register. CPU priority is fixed. This event -> interrupt mapping allows software to define the priority of the event. For more information, see Section 5.4, *IVA2.2 Subsystem Basic Programming Model*.

5.3.1.7.5 Event Combination

The event combiner allows multiple system events to be combined as single event for routing to the interrupt selector. This allows the CPU to service all available system events, even though only 12 are available.

A set of event mask registers (IC.EVTMASKi where i = 0 to 3), is used to program the event combiner. These registers allow up to 32 events to be combined as a single event output that is used as a single DSP CPU interrupt. The event mask bits in the EVTMASKi registers act as enablers for the received system events combined on the event outputs. There are four event outputs to the interrupt selector (EVT[3:0]).

By default, every system event is unmasked and combined with its associated EVTx. To mask out an event source (for example, to disable an event from being combined), the corresponding mask bit (the IC.EVTMASKi[y] EMy bit for EVTy) must be set to 1.

NOTE: Because the event masks for events 0 through 3 are combined events and thus cannot contribute to the generation of a combined event, they are reserved.

For more information, see Section 5.4.8, *Interrupt Management*.

5.3.1.7.6 Interrupt Event Error

The INTC can generate a system event internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is received while the interrupt flag (IFR, internal DSP register) is already set in the CPU. This signals possible problems in the code, such as whether interrupts were disabled for an extended time, or whether pipelined (noninterruptible) code sections were too long.

NOTE: The same strategy of register settings (events, event set, event clear, event mask) is used in the WUGEN (which is not really an INTC), which enables defining wake-up events so that they can wake up the IVA2.2 subsystem. For more information, see Section 5.3.6, *Wake-Up Generator*.

For more information, see Section 5.4.8, *Interrupt Management*. See Section 5.4, *IVA2.2 Subsystem Basic Programming Model*, for information on associated programming.

5.3.1.7.7 PDC Overview

The DSP megamodule PDC allows power management under software control. Different power-down states are defined and can be reached during a period of DSP inactivity. The PDC ensures handshakes with DSP modules so that they go to power-down state in the correct order, on request from the user, and publishes the relevant standby status to the IVA2.2 SYSC module.

The power-down attributes of the DSP components are mapped through the PDC, through the SYS.PDCCMD register.

For information about power-down settings, see Section 5.4.10.3 , *Power-Down and Wake-Up Management*.

5.3.1.8 Other DSP Reference Documents

For more information about the DSP megamodule architecture, the instruction set, and the DSP core interrupt controller, and for a complete description of the DSP memory-mapped registers, see the following documents (www.ti.com):

- *TMS320C6000 DSP Peripherals Overview Reference Guide* (TI literature number SPRU190) describes the peripherals available on the TMS320C6000 DSPs.
- *TMS320C64x Technical Overview* (TI literature number SPRU395) introduces the TMS320C64x DSP and discusses the application areas enhanced by the TMS320C64x VelociT.
- *TMS320C64x+ DSP Megamodule Reference Guide* (TI literature number SPRU871) describes the C64x+ megamodule peripherals.

- *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732)
- *TMS320C6000 Programmers Guide* (TI literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C6000 DSPs, and includes application program examples.
- *TMS320C64x to TMS320C64x+ CPU Migration Guide* application note (TI literature number SPRAA84A)

5.3.2 DMA Engines

5.3.2.1 EDMA

The IVA2.2 subsystem has an EDMA to transfer instructions and data from/to any external memory connected to the L3 interconnect to/from the DSP megamodule L1D and L2 and, potentially, L1P (if not configured as full cache) local memories. The EDMA can also perform transfers from external memory to external memory and from DSP megamodule internal memory to DSP megamodule internal memory, with some performance loss caused by resource sharing between the read and write ports. For DSP megamodule internal memory to internal memory, use the IDMA.

For the IDMA functional description and a description of IDMA relative programming, see Section 5.3.2.3, *IDMA*, and Section 5.4.4.2, *Internal Memory-to-Memory Transfer (IDMA)*, respectively.

The EDMA is based on two primary components:

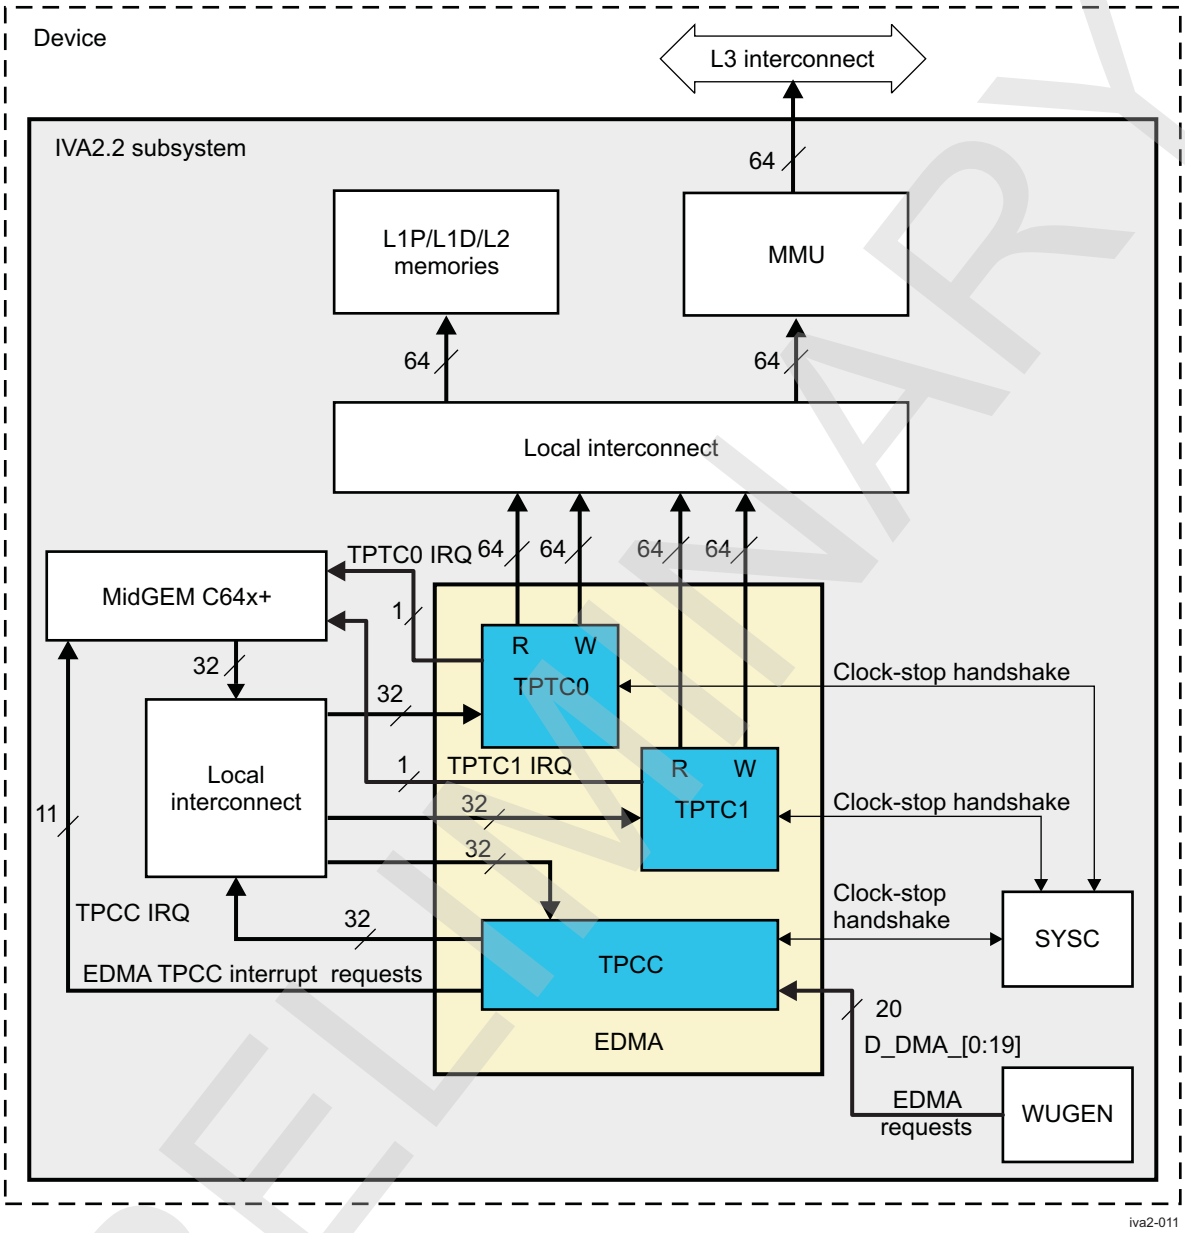
- Third-party DMA channel controller (TPCC)
- Third-party DMA transfer controller (TPTC)

  There are two instances of the TPTC in the IVA2.2 subsystem.

Figure 5-11 shows how the EDMA is integrated in the IVA2.2 subsystem:

- Code running on the DSP can configure the EDMA; through the DSP megamodule configuration port and the local interconnect, the code can program DMA transfers and software-trigger them by writing to the TPCC configuration registers.
- Preprogrammed DMA transfers can be triggered by external events, referred to in this chapter as DMA requests.
- The TPCC schedules DMA transfers to the TPTC DMA engines (TPTC0 and TPTC1) through dedicated local interconnect 32-bit configuration ports.
- Each TPTC issues concurrent traffic on the local interconnect through dedicated read and write 64-bit ports.
- Interrupts generated by the EDMA are routed to the DSP INTC.
- Power-management handshakes are exchanged between EDMA components and the SYSC module.

Figure 5-11. IVA2.2 EDMA Overview



5.3.2.1.1 Third-Party Channel Controller

The TPCC is the DMA transfer scheduler responsible for scheduling, arbitrating, and issuing user-programmed transfers to the two TPTCs.

5.3.2.1.1.1 TPCC Features

The TPCC features are as follows:

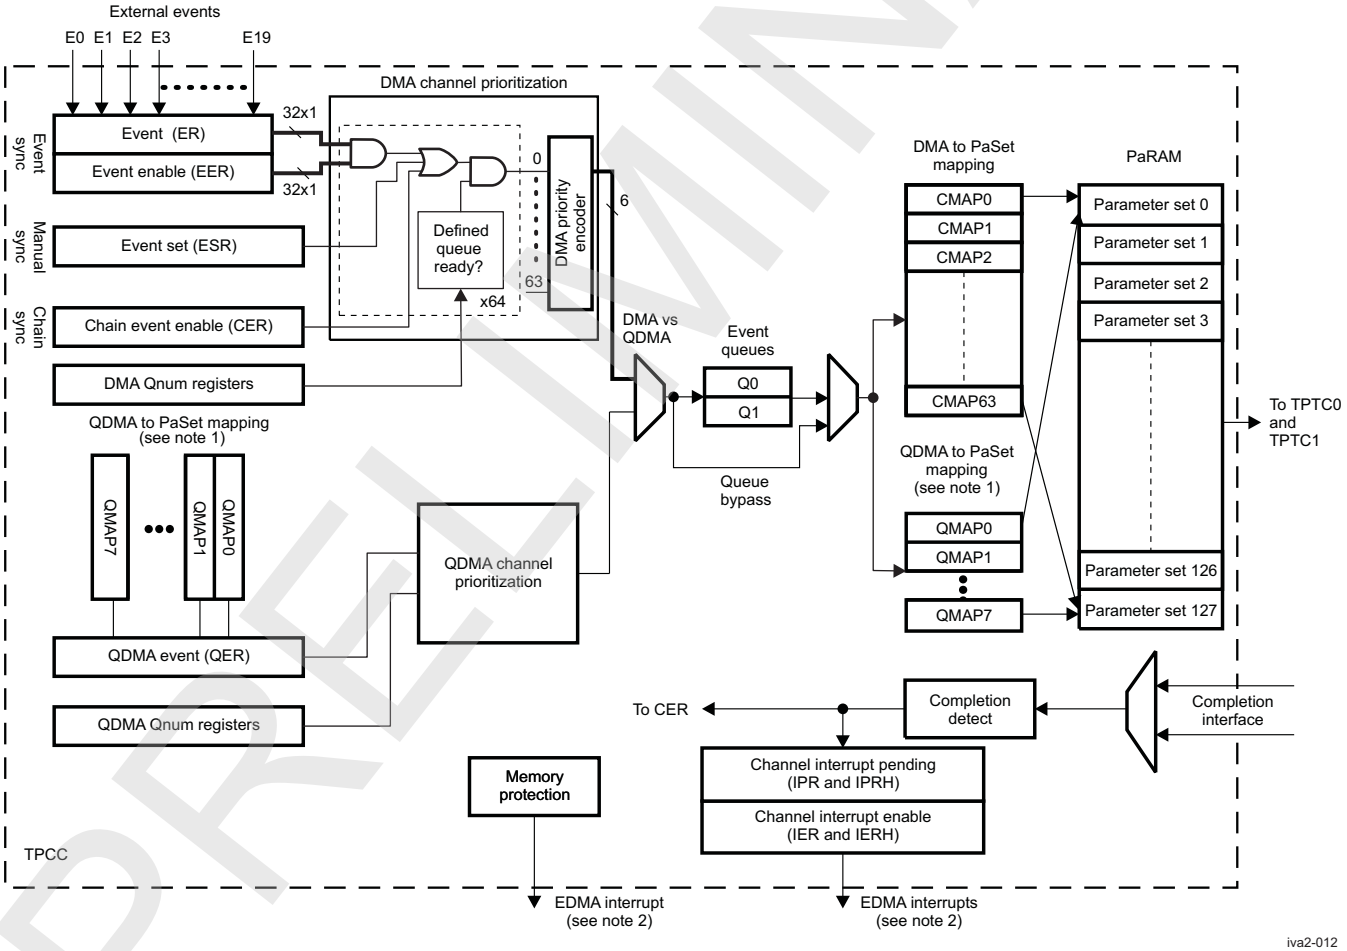
- Parameter RAM (PaRAM entires) holding up to 128 transfer contexts, with the following capabilities:
  - Ping-pong and circular buffering
  - Channel chaining
  - Auto-reloading

Each PaRAM entry can be used as a DMA entry (up to 64), QDMA entry (up to 8), or link entry (remaining):

- Up to 64 DMA logical channels:
  - 64 channels can be triggered explicitly by the DSP CPU (DMA entry).
  - 64 channels can be triggered by 20 external events (see Table 5-2).
  - All channels can be triggered by completion of a previous transfer in a user-programmed chain of transfers (linked entry).
  - 8 channels can be triggered automatically and indirectly by the CPU using the IDMA, reducing CPU offload for DMA configuration (QDMA entry).
- 12 interrupt lines connected to the DSP CPU
- Boundaries for synchronization with the CPU are programmable.
- Two queues holding events waiting for submission to TPTC
- Memory protection
- Each transfer can be programmed to a priority level (three possible levels).

Figure 5-12 is a block diagram of the TPCC.

Figure 5-12. TPCC Block Diagram



NOTE:

1. Although it is depicted twice in Figure 5-12, there is only one physical register set for the QDMA to PaRAM set mapping block.
2. For more information, see Table 5-3.

A channel is a specific event that can cause a transfer to be submitted to the TPTCs as a transfer request. The TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for the ways they are triggered:

- DMA channels can be triggered by external events (such as McBSP TX Evt and McBSP RX Evt) by the software writing 1 to a given bit location or channel, by the event set register, or through chaining.
- QDMA channels are triggered automatically (auto-triggered) by the CPU using the IDMA. QDMAs allow a minimum number of linear writes (optimized for the DSP IDMA feature) to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among all pending DMA/QDMA events with a fixed 64:1 and 4:1 priority encoder for DMA and QDMA events, respectively (a low channel number corresponds to a high priority). DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controller, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority, Q0 higher than Q1. When an event is ready to be queued and both the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the TR bus/PaRAM processing is busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the TPTC is available for a new TR to be programmed into the TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry. The PaRAM entry consists of eight words of DMA context, including source address, destination address, count, indexes, etc.

5.3.2.1.1.2 DMA Versus QDMA

The only difference between a QDMA and a DMA transfer is the specific means of generating/recognizing TR synchronization. From the user point of view, DMA and QDMA transfer types can be combined to perform various types of transfers.

DMA channel TR synchronization can be generated from one of three sources:

- Event-triggered: The event register (TPCC_ER) channel *n* bit is set as the result of an external event. An external event is latched in the event register. If the corresponding event is enabled through the event enable register (TPCC_EER), this is recognized as a TR synchronization.
- Manually triggered: The event set register channel *n* bit is set manually to the event set register (TPCC_ESR and TPCC_ESRH registers) for channel *n* (TPCC_ESR[*n*] E*n* bit or TPCC_ESRH[*n*] E*n* bit). Manually set events do not need to be enabled to be recognized as a TR synchronization.
- Chain-triggered: The chain event register channel *n* (TPCC_CER and TPCC_CERH registers) bit is set when a chaining completion code is detected on the completion interface for channel *n*. Chain events do not need to be enabled. If a chain trigger is detected, this is always recognized as a TR synchronization.

QDMA TR synchronization occurs one of two ways:

- Auto-triggered: The QDMA event register channel *n* (TPCC_QER and TPCC_QERH[*n*] E*n*) bit is set when a CPU write address matches the address defined by the QDMA mapping register for channel *n* (TPCC_QCHMAPj) and the QDMA channel is enabled (TPCC_QEER[*n*] E*n* bit field).
- Link-triggered: The TPCC_QER[*n*] E*n* bit is set when a link update is performed on a PaRAM address that matches the TPCC_QCHMAPj setting, and the TPCC_QEER[*n*] E*n* bit is set.

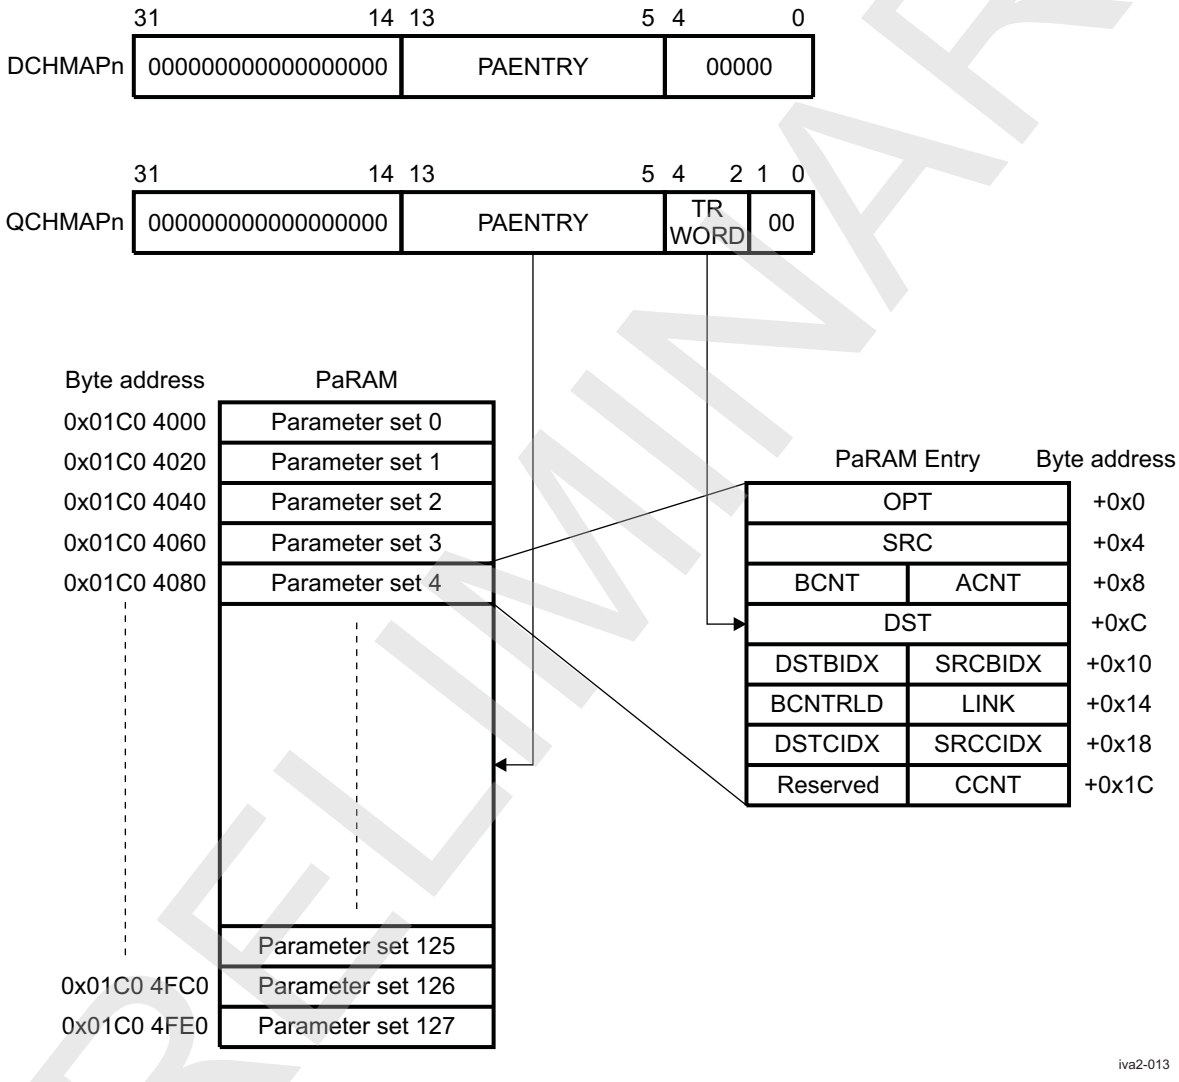
There is a subtle difference between each trigger type and the associated enablers. Event assertion always results in the TPCC_ER[*n*] E*n* bit being set, regardless of the state of the enable (TPCC_EER.E*n*). It is recognized as a TR synchronization only if enabled. Chain triggering always sets the TPCC_CER[*n*] E*n* bit and is always treated as a TR synchronization. Manual triggering always sets the TPCC_ESR[*n*] E*n* bit and is always treated as a TR synchronization. Auto-triggering (QDMA) sets only the event register TPCC_QER[*n*] E*n* bit only if the corresponding event is enabled (TPCC_QEER[*n*] E*n*); when the TPCC_QER[*n*] E*n* bit is set, it is always treated as a TR synchronization.

For more information, see Section 5.4, *IVA2.2 Subsystem Basic Programming Model*.

5.3.2.1.1.3 DMA/QDMA Channel Mapping and PaRAM Entry

The DMA and QDMA channel mapping registers (TPCC_DCHMAPi and TPCC_QCHMAPj) allow each DMA and QDMA channel to be mapped to arbitrary locations in the PaRAM memory map. The entry is designated with a 9-bit PAENTRY (TPCC_DCHMAPi[13:5] PAENTRY and TPCC_QCHMAPj[13:5] PAENTRY bit fields) PaRAM entry number that defines the entry number in a 128-entry maximum PaRAM (see Figure 5-13). TPCC_QCHMAPj[4:2] TRWORD points to the trigger word of the PaRAM entry defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.

Figure 5-13. DMA/QDMA Channel Mapping and PaRAM Entry



NOTE: Each parameter entry of PaRAM is organized as eight 32-bit words or 32 bytes, as shown in Figure 5-13.

The location of fields in each entry, as well as bit positions in the options field, must match the TR packet format as closely as possible to the requirements of the TPTC0 and TPTC1 programming. Each PaRAM entry consists of 16-bit and 32-bit parameters that correspond to the transfer geometry. For more information about the parameters, see Section 5.3.2.1.1.2, *DMA Versus QDMA.*

5.3.2.1.1.4 Types of TPCC Transfers

The TPCC streamlines transfers into an orthogonal transfer structure that is always defined by three dimensions. Of the three dimensions, only two synchronization types are supported: 1D synchronized transfers and 2D synchronized transfers; 3D synchronized transfers can be logically achieved by chaining.

The following terms are used:

- 1-dimension (1D) transfer or array: ACNT contiguous bytes transfer. For information about the 1D transfer programming model, see Section 5.3.2.1.1.5, *Transfer Synchronization*.
- 2-dimension (2D) transfer or frame: BCNT arrays of ACNT bytes transfer. Each array transfer in 2D transfer is separated from the other transfers by an index programmed through the TPCC.SBIDX or TPCC.DBIDX registers.
- 3-dimension (3D) or block: CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the third dimension is separated from the previous transfer by an index programmed by the TPCC.SCIDX or TPCC.DCIDX registers. The reference point for the index depends on the synchronization type.

5.3.2.1.1.5 Transfer Synchronization

In a 1D synchronized transfer, each TPCC TR synchronization triggers the transfer of the first dimension of ACNT bytes, or one array of ACNT bytes. In other words, each TR packet consists of transfer information for only one array. Arrays can be separated by SBIDX and DBIDX, as shown in Figure 5-13, where the start address of array N equals the start address of array 1 plus SRC or DST BIDX. Frames can be separated by SCIDX and DCIDX. For 1D synchronized transfers, after the frame is exhausted, the address is updated by adding (S|D)CIDX to the beginning address of the last array in the frame.

Contrast this to the (S|D)CIDX update in 2D synchronized transfers, which are referenced from the beginning address of the first array in the previous frame. For information about parameter updates, see Section 5.3.10, *Error Reporting*.

In a 2D synchronized transfer, each TR synchronization triggers the transfer of two dimensions or one frame. In other words, each TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Arrays can be separated by SBIDX and DBIDX, as shown in Figure 5-15. Frames can be separated by SCIDX and DCIDX. For 2D synchronized transfers, after a TR for the frame is submitted, the address is updated by adding (S|D)CIDX to the beginning address of the beginning array in the frame. Contrast this to the (S|D)BIDX update in 1D synchronized transfers. For information about parameter updates, see Section 5.3.10, *Error Reporting*.

5.3.2.1.1.6 DMA Channel Prioritization

If multiple trigger sources (event trigger/chain trigger/manual trigger) for a single channel are active at the same time, the TPCC services events in the following order:

1. Event trigger (through event register [ER])
2. Chain trigger (through chain event register [CER])
3. Manual trigger (through event set register [ESR])

5.3.2.1.1.7 Transfer Completion

Transfer completion can be used for two different mechanisms in the TPCC:

- Generating chained events
- Generating interrupts to an external processor

The underlying mechanism for both features is the same. The user programs the PaRAM Options field with a specific transfer completion code (TPCC_OPTm[17:12] TCC) and indicates whether that completion code is to be used to generate a chained event and/or to generate an interrupt on completion of a transfer (either or both can be done). The user can selectively program whether completion signaling is enabled for the final TR of a PaRAM set, for all except the final TR of a PaRAM set, or for all TRs of a PaRAM set. The specific TCC value (6-bit binary value) programmed by the user dictates which bit of the 64-bit CER and/or interrupt pending register (IPR) is used.

There is no direct correlation between the TCC value used for a specific PaRAM entry and the channel number for that entry. Software controls the allocation of TCC values. There is always a 1:1 relationship between the TCC value and the IPR bit and/or the CER bit set when that transfer completes. For example, completion of the PaRAM entry for channel 0 can chain-trigger the PaRAM entry for channel 1.

5.3.2.1.2 Third-Party Transfer Controller

The TPTC is the DMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

NOTE: The port data bus width of the instances of the TPTC is fixed at 64 bits.

5.3.2.1.2.1 TPTC Features

The TPTC features are as follows:

- Pipelined transfers (multiple inflight transfers)
- Background programming
- 2D or 1D transfer
- Increment addressing modes
- Clock-stop handshaking with the SYSC controller
- Programmable tracking of transfer completion
- 2D qualifications of transfers to allow 2D bandwidth optimization

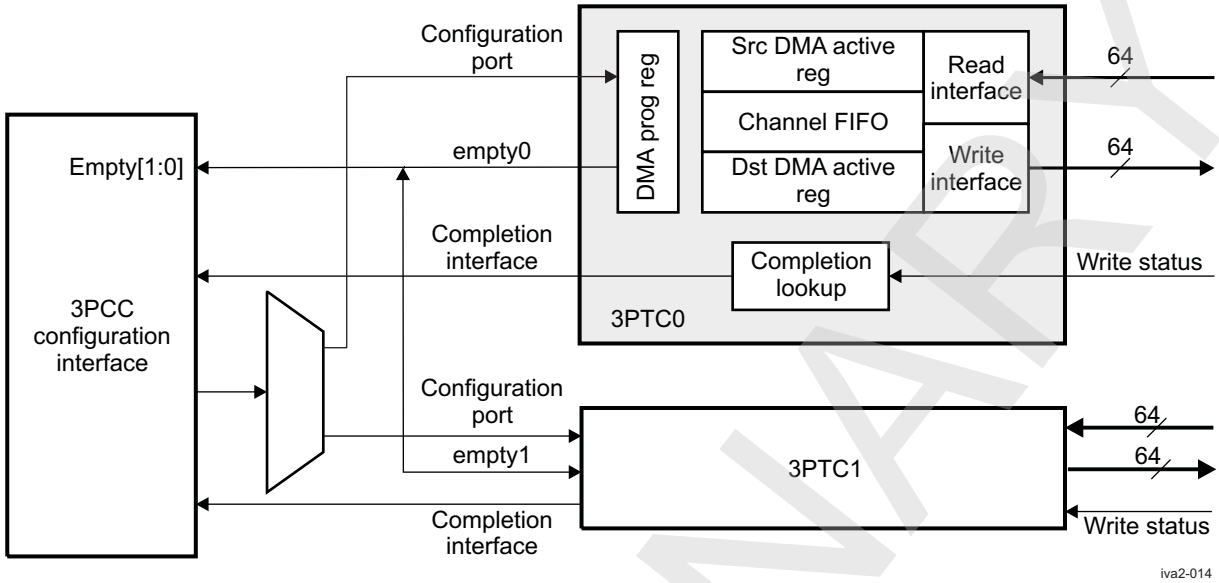
Two instances of the TPTC generate concurrent traffic on the IVA2.2 local interconnect. Each TC controller consists of the following components:

- DMA program register set: Stores the context for the DMA transfer that is loaded into the active register set on completion of the current active register set. The CPU or TPCC programs the program register set, not the active register set. For typical stand-alone operation, the CPU programs the program register while the TC services the active register set. The program register set includes ownership control that synchronizes the CPU software and the DMA.
- Source DMA active register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress in the read controller. The active register set is split into independent source and distant register halves, because the source local interconnect controller and distant local interconnect controller operate independently of each other.
- Distant DMA register set: Stores the context (src/dst/cnt/etc) for the DMA transfer request in progress, or pending, in the write controller. The pending register sets are required to allow the source controller to begin processing a new TR while the distant register set is still processing the previous TR.
- Channel FIFO: Temporary holding buffer for inflight data. The read return data of the source peripheral is stored in the data FIFO and then written to the destination peripheral by the write command/data bus.
- Read controller/local interconnect read interface: The local interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and the available landing space in the channel FIFO.
- Write controller/local interconnect write interface: The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- Completion interface: The completion interface sends completion information to the TPCC for posting interrupts in the TPCC.
- Configuration port: Slave interface that provides read/write access to program registers, and provides read access to all memory-mapped TC registers. For information about TPTC registers, see Section 5.5, *IVA2.2 Subsystem Register Manual*.

Table 5-4 lists the hardware settings.

Figure 5-14 shows the internal structure of the TPTC and its connection to the TPCC.

Figure 5-14. TPTC Block Diagram



The primary responsibility of the TPTC is to perform read and write transfers through the local interconnect to the slave peripherals, as programmed in the active and program register sets:

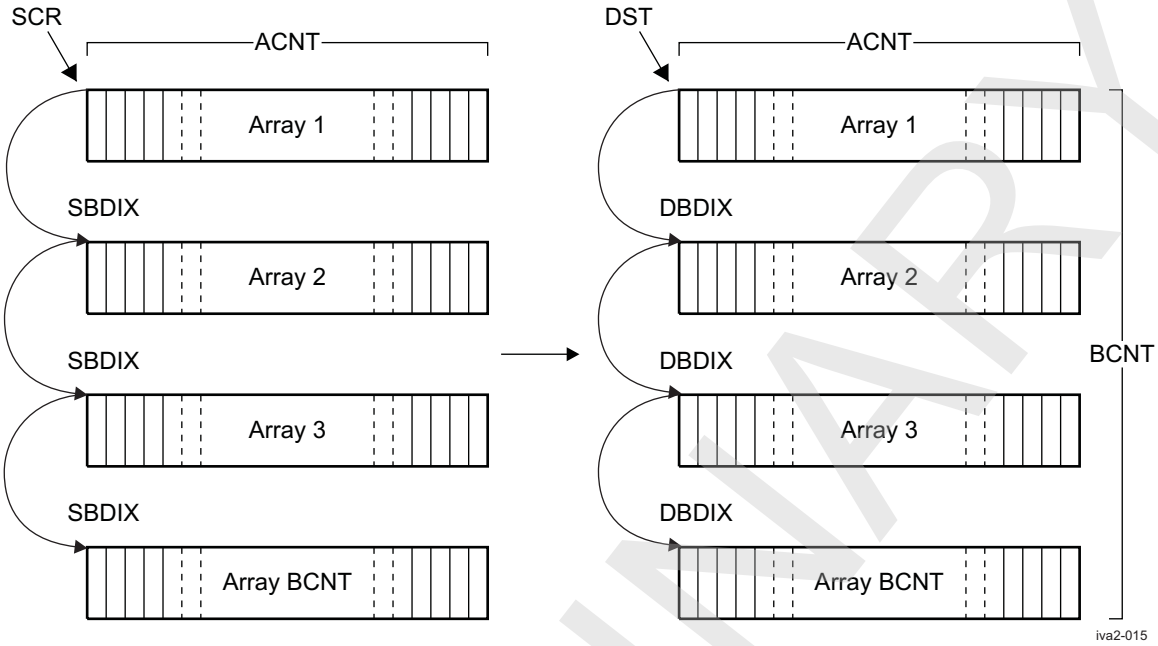
- In the TC stand-alone use model, the user directly programs the program and active register sets for a given channel (TPTC0 or TPTC1). Because of the TPCC, this mode is not the use case targeted for device applications, so it is not emphasized in this chapter. For information about its programming model, see Section 5.4.4.6.6, *Direct Configuration to Transfer Channel (Not Recommended)*.
- In the TC external-control use model, the user does not directly program the active and program register sets. Instead, the TPCC is the user interface to the EDMA system, and the TPTCs (TPTC0 and TPTC1) are slaves to the TPCC. This is the use case of the EDMA in device applications.

5.3.2.1.2.2 Transfer Geometry

The TPTC supports a transfer geometry fully defined by the registers summarized here (see Figure 5-15).

- OPTx = options, (where x = 0, 1)
  - SAM = Source address mode, controls whether the source array is from incrementing addresses or from a single FIFO address
  - DAM = Distant address mode, controls whether the destination array is to an incrementing address or to a single FIFO address
  - FWID = Controls the width of the FIFO
- SRC = Source address
- DST = Distant address
- CNT = BCNT, ACNT
  - ACNT = Number of bytes in each array
  - BCNT = Number of arrays in each TR
- BIDX = DBIDX, SBIDX
  - SBIDX = Source B-dimension index, defines the address offset between starting addresses of each source array
  - DBIDX = Distant B-dimension index, defines the address offset between starting addresses of each destination array

Figure 5-15. Transfer Geometry



NOTE: Many Texas Instruments DMA controllers employ a concept of element size and element indexing. To maintain orthogonality, the concept of element size has been dropped. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that must be transferred.

5.3.2.1.2.3 Tracking Transfers

Each TPTC channel consists of three register sets: a program register set, a source-active register set, and a distant FIFO register set. The status of each of these register sets is indicated by the PROGBUSY, SRCACTV, DSTACTV, and WSACTV status bits, which are user-readable in the TPTCj_TCSTAT register.

The program register set (TPTCj_POPT, TPTCj_PSRC, TPTCj_PCNT, TPTCj_PDST, TPTCj_PBIDX, and TPTCj_PMPPRXY) is never modified by the TPTC, because they are simply holding registers processed by the active register sets. The source active register set (TPTCj_SAOPT, TPTCj_SASRC, TPTCj_SACNT, TPTCj_SADST, TPTCj_SABIDX, TPTCj_SAMPPRXY, TPTCj_SACNTRLD, TPTCj_SASRCBREF, and TPTCj_SADSTBREF) tracks commands for the source side of the transfer, and the distant FIFO register set (TPTCj_DFOPTi, TPTCj_DFSRCi, TPTCj_DFCNTi, TPTCj_DFDSTi, TPTCj_DFBIDXi, and TPTCj_DFMPPRXYi) tracks commands for the distant side of the transfer.

As the source and distant controllers process a TR, the SRC, DST, and CNT fields must be continuously updated as commands are issued. A reference value for these registers is also maintained. The active register set uses the reference address (SRCBREF and/or DSTBREF) to calculate the addresses of the subsequent arrays in a transfer. This is required because subsequent arrays are defined as an offset from the starting address of the current array. Similarly, when a new array begins, the CNT must be restored (from CNTRLD) to the originally programmed value and decremented as the new array is processed.

The following summarizes register use for the active register sets:

- Static fields
  - OPT
  - BIDX = DBIDX/SBIDX
- Dynamic fields
  - SRC = Source address of the next read command to be issued
    - Tracked by source active register set

  - DST = Distant address of the next write command to be issued
    - Tracked by distant FIFO register set
  - CNT = BCNT/ACNT
    - BCNT = Number of arrays remaining to be transferred. This includes the current array; that is, BCNT is decremented after all commands for an array are issued (or at least after all read or write commands are scheduled).
    - ACNT = Number of bytes remaining to be transferred
    - Tracked independently in source and distant FIFO register sets
- Reference fields
  - CNTRLD = ACNTRLD only
    - CNTRLD.ACNTRLD is set with the initial CNT.ACNT value. The reload value is copied into CNT.ACNT when CNT.ACNT decrements to 0.
    - Tracked independently in source and distant FIFO register sets

    Because a command is complete when BCNT decrements to 0, there is no BCNT reload value.
  - SRCBREF = Source address reference points to the starting address of the array being read. The starting address of the next array is calculated as SRCBREF + SBIDX.
    - Tracked by source active register set
  - DSTBREF = Distant address reference points to the starting address of the array being written. The starting address of the next array is calculated as DSTBREF + DBIDX.
    - Tracked by distant FIFO register set

5.3.2.1.2.4 Completion Interface to TPCC

The TPCC can request that the TPTC send completion information to the TPCC when a TR completes. Completion status is requested in the TR options registers (TPTCj_DFOPTi[20] TCINTEN and TPTCj_DFOPTi[22] TCCHEN bits, and TPTCj_DFOPTi[17:12] TCC where i = 0 to 3 when j = 0 and i = 0 or 1 when j = 1).

If TCINTEN or TCCHEN is set to 1, the TPTC must return completion information on completion of the entire TR. The TPCC uses completion information for chaining (enabled by TCCHEN) or for posting interrupts (enabled by TCINTEN).

The TPTC generates status conditions based on completion of a transfer (TPTCj_INTSTAT[1] TRDONE bit) and based on the program register set transitioning to the downstream registers (TPTCj_INTSTAT[0] PROGEMPTY bit).

These two conditions can be enabled by the corresponding bits in the TPTCj_INTEN register to generate an interrupt to the DSP CPU through the TCERRINTx interrupt line (TCERRINT0 for TPTC0 and TCERRINT1 for TPTC1). For the event mapping of these interrupt lines, see Table 5-2.

NOTE: Status bits TRDONE and PROGEMPTY are always available and are stored in the TPTCj_INTSTAT register regardless of use model and regardless of whether the corresponding bits are enabled. Typically, these bits are not used in the TPCC use model. They are used in a stand-alone use model in which the user directly programs the TC.

For more information about EDMA completion and its programming model, see Section 5.4.4.1, *Transfers From/to Device Memories/Peripherals (EDMA)*.

5.3.2.1.3 EDMA Hardware Parameters

Table 5-4 lists the hardware parameter settings for the IVA2.2 subsystem.

Table 5-4. IVA2.2 EDMA Hardware Parameters

Module		Parameter	IVA2.2
EDMA	TC	FIFO size for TC0	256 bytes
		FIFO size for TC1	128 bytes

Table 5-4. IVA2.2 EDMA Hardware Parameters (continued)

Module		Parameter	IVA2.2
		Data bus width	64 bits
		TR pipelining depth TC0	4
		TR pipelining depth TC1	2
		Endianness	Little
		Burst size	64
	CC	Number of DMA channels	64
		Number of QDMA channels	8
		Number of PaRAM entries	128
		Number of Event Qs	2
		Number of TPTCs	2

NOTE: The TR pipelining depth controls the number of read TRs for a given transfer channel that can be serviced by the source transfer controller without being serviced by the distant transfer controller. This dictates the amount of storage required in the distant queue channel registers for inflight TRs

The user cannot directly program burst size, as with the sDMA, but must rely on the ACNT/BCNT and issue 1D synchronization transfers to do so.

5.3.2.2 EDMA Access to Video Accelerator/Sequencer

To improve performance and to offload themselves, the DSP megamodule and sequencer can both program the EDMA in IVA2.2 to transfer memory to/from the video accelerator/sequencer (sequencer, iLF, iME, iVLCD) to/from external memories. The DSP megamodule programs the EDMA through the IVA2.2 local interconnect, whereas the sequencer programs the EDMA through the video and sequencer local interconnect. The EDMA can access the following module registers and memories in the video accelerator/sequencer:

- iME configuration registers
- iLF configuration registers
- iVLCD configuration registers and memories
- Sequencer memories
- SL2 memory (access through the IVA2.2 local interconnect)

The DMA accesses the video and sequencer modules with the memory mappings listed in Table 5-5.

Table 5-5. EDMA Memory Mapping for the Video Accelerator/Sequencer

5.3.2.3 IDMA

The IDMA is a simple DMA engine that performs block transfers between any two memory locations local to the DSP megamodule. A local memory has a controller that is included in the DSP megamodule. Local memory can be L1P, L1D, or L2 memories or DSP megamodule port configuration for an offloaded configuration. The IDMA controller consists of two DMA channels (channel 0 and channel 1) that can be independently programmed (a dedicated set of registers) to perform block moves between internal DSP megamodule resources.

IDMA channel 0 is used only to configure registers of IVA2.2 modules connected to the DSP megamodule configuration port, and it is useful for the DMA PaRAM entries.

To allow an easy configuration of IVA2.2 modules, the IDMA channel contains five registers: status, mask, source address, destination address, and window count.

For information about the use of channel 0 for an offloaded configuration, see Section 5.4.4.6.5, *Offloaded Configuration (Using IDMA).*

IDMA channel 1 allows transfers between any two DSP megamodule local internal memories (L2, L1P, L1D). Channel 1 is intended for background transfers in internal memory, such as block moves between the relatively high-latency L2 and the zero-latency L1D SRAM. This lets the CPU process data directly within L1D with minimal CPU impact.

For more information, see Section 5.4.4.2, *Internal Memory-to-Memory Transfer (IDMA).*

5.3.3 MMU

The IVA2.2 MMU communicates accesses from the DSP core of the IVA2.2 subsystem to the L3 interconnect, mapping the 4G bytes of the DSP virtual addresses to any place in the 4G-byte address space of the device.

At reset, the MMU is disabled, and the IVA2.2 DSP CPU can access device global memory mapping from the 0x1100 0000 address. The range of addresses 0x00000000 to 0x10FF FFFF is reachable only by the DSP CPU, because it performs its own internal memory-mapping function. For more information, see Chapter 2, *Memory Mapping*.

The IVA2.2 MMU main features are:

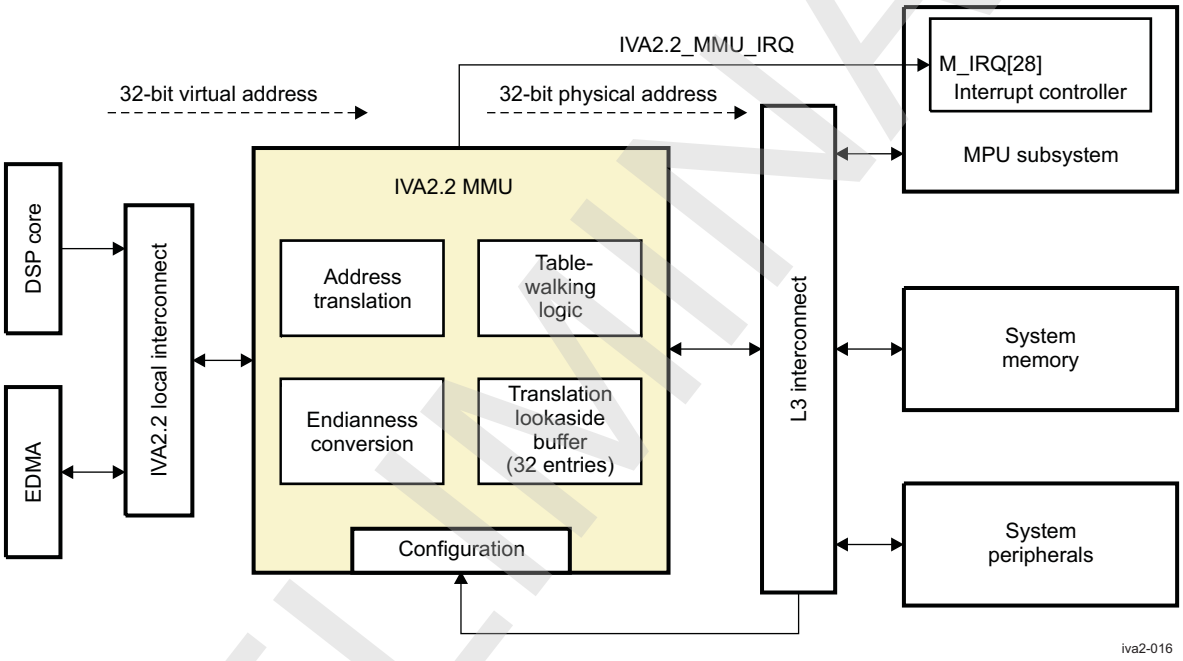
- 32 entries/fully associative translation lookaside buffer (TLB)

- One interrupt line to the MPU
- 32-bit virtual addresses, 32-bit physical addresses
- 4-KB and 64-KB pages, 1-MB section, 16-MB supersection
- Predefined (static), software-driven (interrupt-based) or table-driven (hardware table-walker) software translation strategies

NOTE: The endianness conversion capability of the MMU module is not used in the IVA2.2 subsystem (the DSP is configured as a little-endian processor in the device). With this configuration, the MMU2.MMU_RAM[9] ENDIANNESS bit setting is ignored, even if the user changes the value.

Figure 5-16 shows the integration and functionality of the IVA2.2 MMU module.

Figure 5-16. IVA2.2 MMU Block Diagram



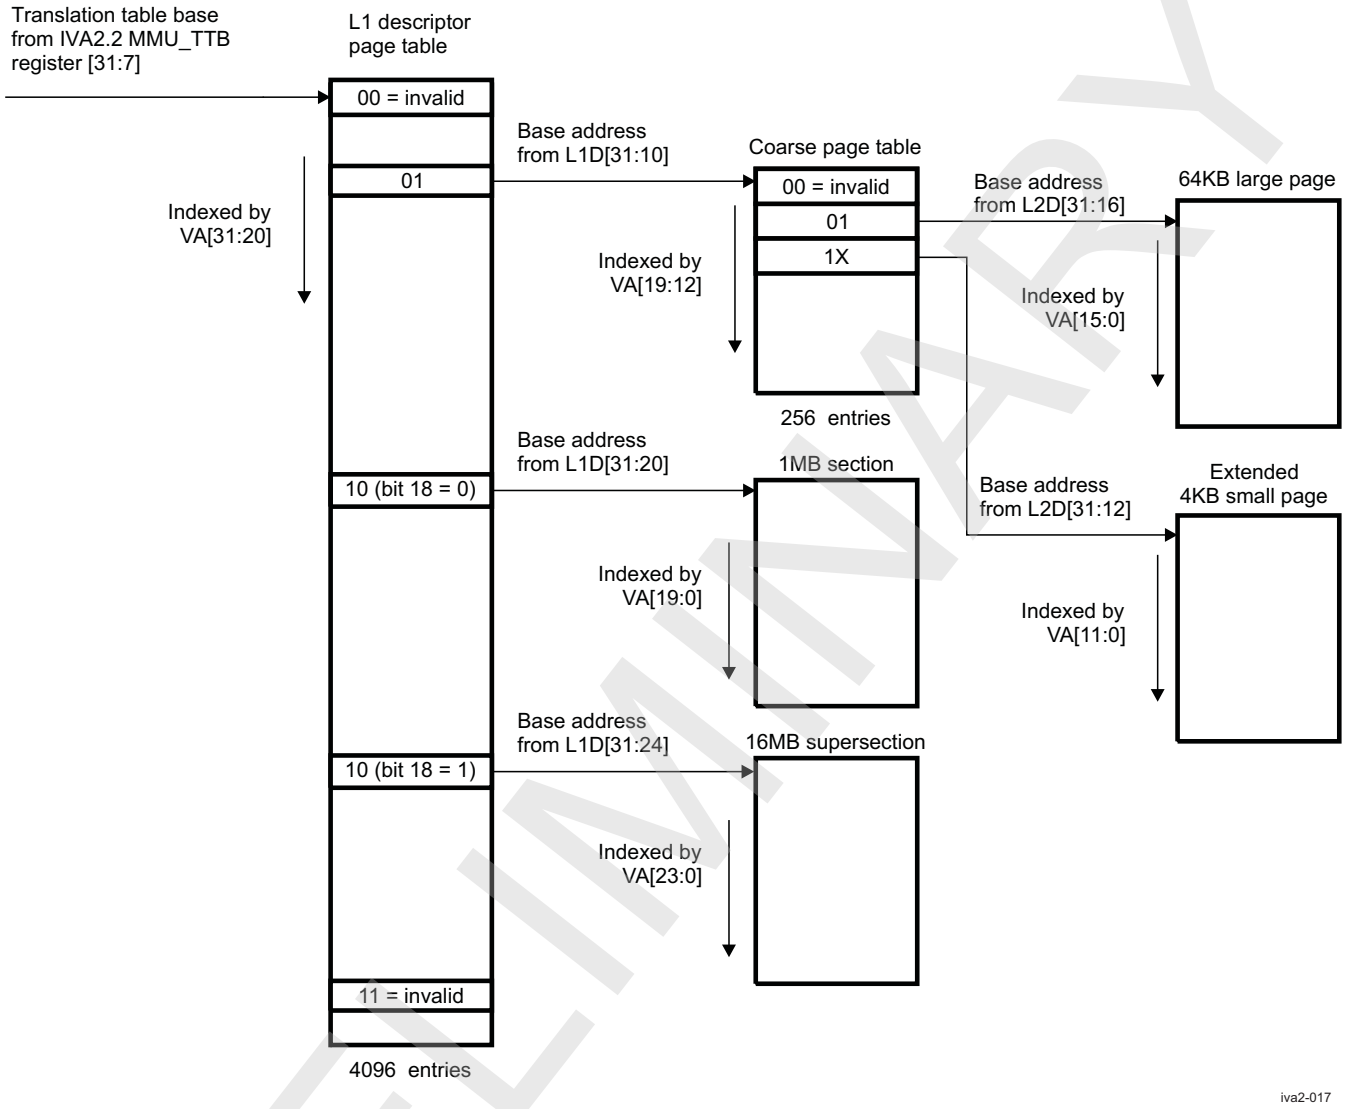
5.3.3.1 MMU VA-to-PA Translation

The IVA2.2 MMU translates the 32-bit DSP external addresses to physical addresses in the 32-bit MPU address space. Address translation is performed by a translation table structure (TTB) that maps the most-significant bits (MSBs) of the DSP byte address to another set of MSBs of a 32-bit MPU byte address. The least-significant bits (LSBs) of the DSP-generated byte address are used as page/section indices in the address translations and are not altered when forming the new 32-bit physical address. The TTB translations are expedited by a TLB that serves as a cache of recently used page translations. The address mapping can be programmed at the TTB level or by writing the TLB entries directly. The IVA2.2 MMU contains 32 TLB entries that can be configured to remap 4-KB, 64-KB, 1-MB, or 16-MB segments of memory.

The TLB can be managed statically or dynamically (through the use of interrupts) by the MPU OS, but the MMU also includes hardware table-walking logic that lets the MMU autonomously traverse the page table on a TLB miss. On a TLB miss, the translation table-walking logic automatically retrieves the information from the translation table stored in physical memory and updates the TLB cache.

Figure 5-17 shows the TTB structure in detail.

Figure 5-17. IVA2.2 MMU Translation Table Hierarchy



NOTE: The MMU passes the lower bits of the virtual address unchanged.

5.3.3.2 MMU Configuration

If the IVA2.2 MMU requires software intervention, the MPU services the event; IVA2.2 MMU service requests are signaled to the MPU with a dedicated interrupt, M_IRQ[28].

Generally, the MMU is initialized at boot time, but it can also be dynamically reprogrammed. Typically, the MMU is programmed by the MPU through the IVA2.2 slave port on the L3 interconnect when a new task is created on the IVA2.2 subsystem. But the DSP also has access to the MMU configuration registers for the save and restore process. At reset, MMU is disabled and DSP virtual addresses are passed directly through as physical addresses (not translated). IVA2.2 MMU configuration registers are at system base address 0x5D00 0000.

For more information about the functionality of the IVA2.2 subsystem MMU module, including interrupts, register descriptions, and programming model, see Chapter 15, *Memory Management Units*.

5.3.4 Video Accelerator/Sequencer Local Interconnect

The video accelerator/sequencer local interconnect allows the DSP megamodule and the sequencer to access the coprocessor, the sequence and video accelerator system control, the shared L2 memory interface, and the IVA2.2 EDMA.

All sequencer reads and writes are performed through the video accelerator/sequencer local interconnect. The DSP can access the interconnect with EFI instructions (EFSDW, EFSW, EFRW, and EFRDW). A write is always composed of an EFSDW (32b). Depending on the destination value associated with the instruction, the pair of DSP megamodule registers contains either the address (32b; only the lowest 20 bits are significant) and the 32b data, or only the 64b data (auto-incrementing, constant addressing mode). A read is composed of a pair of EFSW and EFRW or EFRDW, depending on the size of the read data. For consistency, reads have the same addressing modes as writes.

NOTE: The DSP accesses the shared L2 memory and the IVA2.2 EDMA through the IVA interconnect.

Table 5-6 shows the video accelerator/sequencer interconnect memory mapping. Addresses correspond to the DSP megamodule address using the EFI instruction.

For more information about EFI instruction in IVA2.2, see Section 5.4.5, *IVA2.2 Extended Function Interface*.

Table 5-6. Video Accelerator/Sequencer Memory Mapping

Device Name	Start Address (Hex)	End Address (Hex)	Size	Description

5.3.5 SL2 Interface

The SL2 memory interface (SL2IF) provides access to L2 memory for the following units:

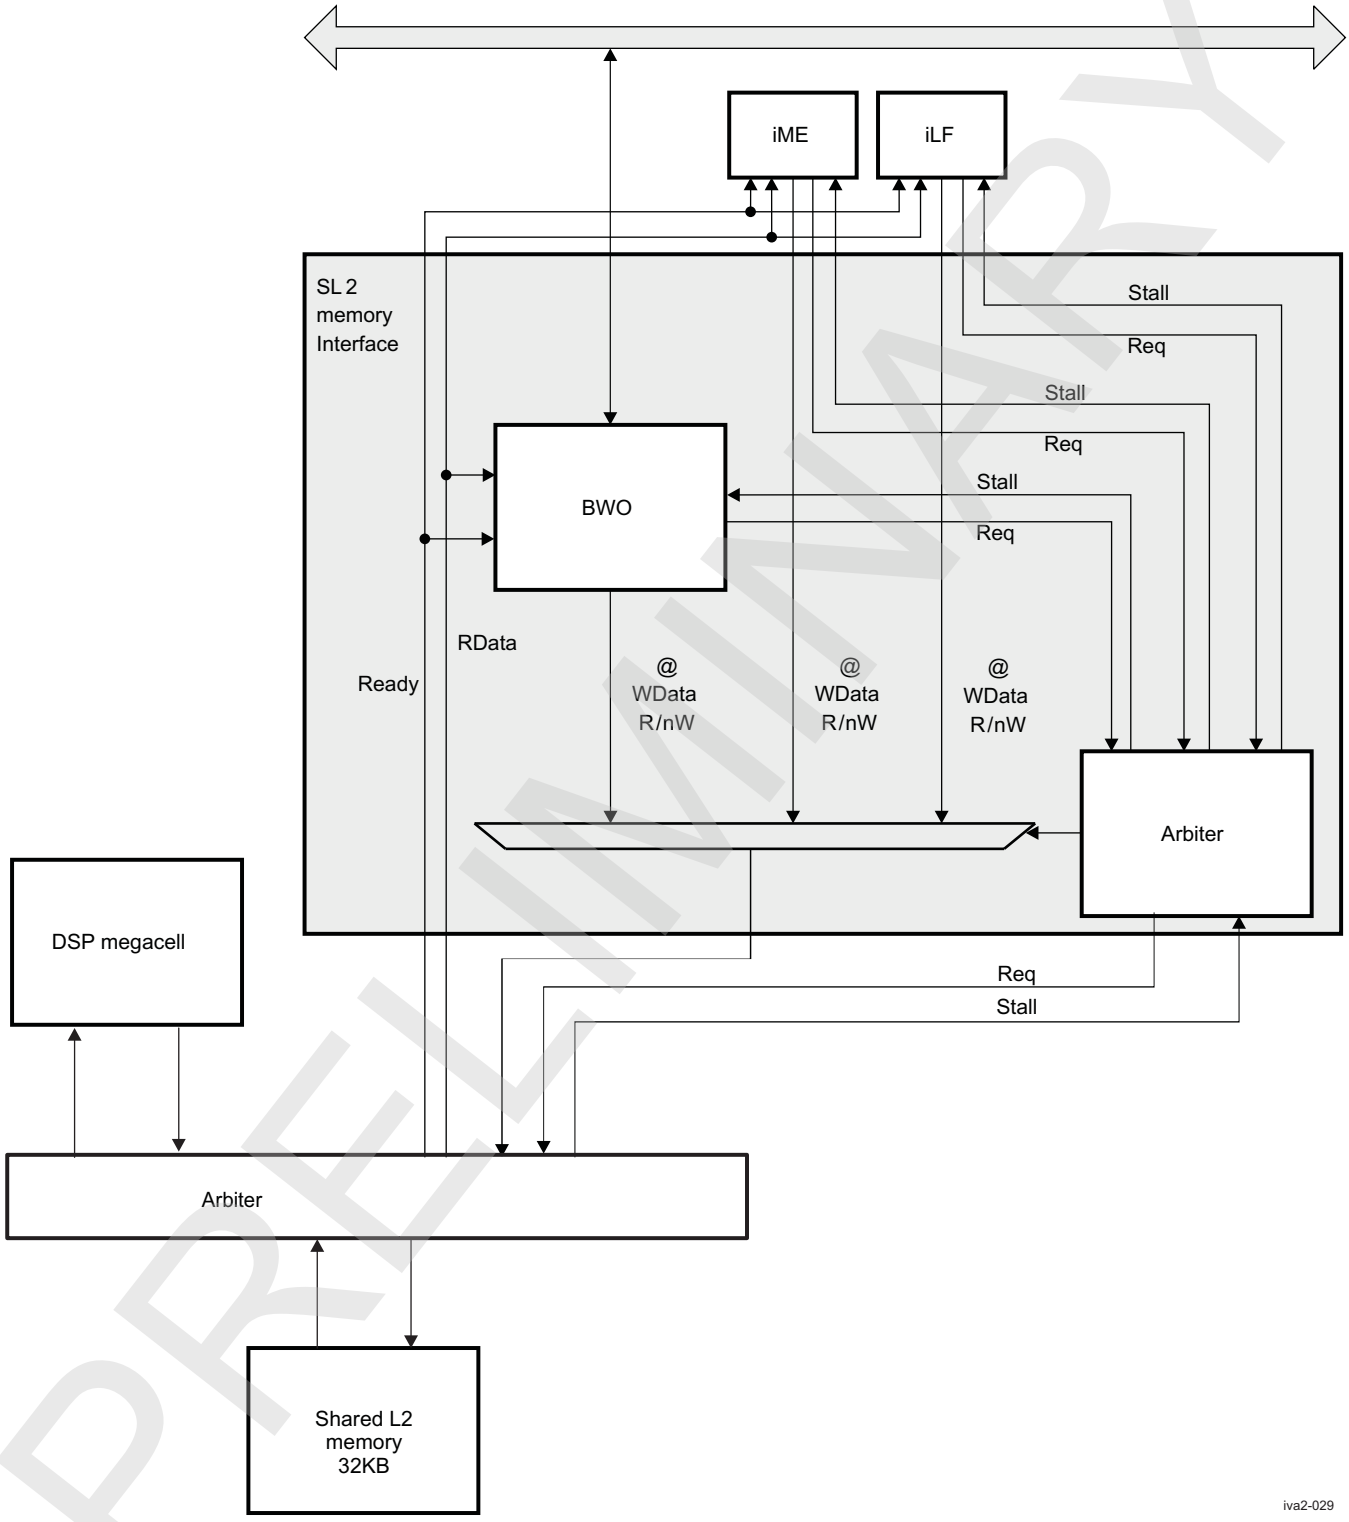
- iME
- iLF
- Video accelerator/sequencer interconnect

The SL2 memory interface is composed of two modules:

- Bandwidth optimizer (BWO) for video accelerator/sequencer local interface interconnect
- Arbiter

Figure 5-18 is a block diagram of the SL2 memory interface.

Figure 5-18. SL2 Memory Interface Block Diagram



5.3.5.1 BWO

The BWO optimizes write bandwidth and read latency for connections from/to the local interconnect from/to the shared L2 memory. It has two components:

- 256b write buffer to gather bursted write data before sending them to the shared L2

- 256b read buffer to prefetch a read line from which the burst is read

These buffers are completely decoupled; writes use the write buffer and reads use the read buffer. This is not a data cache, as there is no load-forwarding from the write buffer, and no prefetch buffer to be updated by an incoming write.

NOTE: There is no concept of dirty bit and write-back policy.

5.3.5.2 Arbiter

The arbiter allows the three modules (iME, iLF, BWO) to access L2 memory without taking care of concurrent access themselves. No bubble is introduced by the arbitration, which means that when a request is initiated by the iME, the iLF, or the BWO, a request is transmitted to the SL2. This arbitration ensures 100 percent bandwidth use. The arbitration is fair and does not starve an initiator for more than three cycles.

To return data to the correct initiator, the arbiter keeps track of the ordering of memory requests committed to the SL2 memory interface.

The SL2 memory interface can sustain a 2x16-byte request per SL2 memory interface clock cycle, whether the request is a read or write or interleaved reads and writes, and regardless of which module generates the request (iME, iLF, or local interconnect port initiators), if the initiator is not preempted by the others (no competition) and provides an equivalent input throughput.

5.3.5.3 Restrictions on SL2 Memory Usage

Because accesses to SL2 (from iME, iLF, or any other initiator with access to the SL2IF interface) are not checked for access permission, the SL2 memory must not be used for memory-protected or sensitive data.

SL2 memory must not be used to store sequencer instructions to be fetched directly by the sequencer; the SL2IF is not designed to efficiently serve sequencer instruction fetches. SL2 memory can hold sequencer instructions, but they must be transferred by the EDMA module into the ITCM before being executed.

5.3.5.4 Error Management

The SL2 memory interface responds to the following conditions with an in-band error (SResp = ERR):

- Nonaligned address (MAddr[1:0] <>0)
- Unsupported command (MCmd not belonging to READ/WR/WRNP)

All valid accesses are propagated to the SL2 memory interface; the address must always be mapped in SL2.

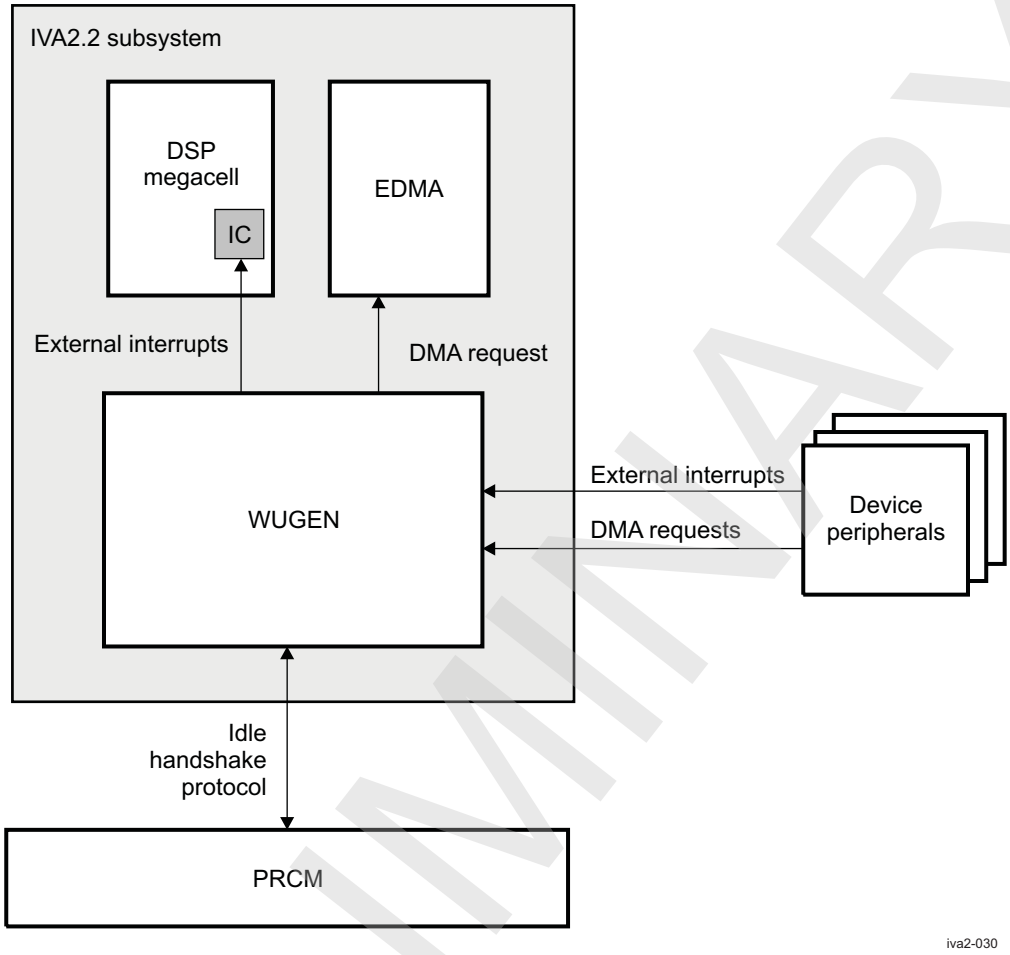
5.3.6 Wake-Up Generator

The wake-up generator (WUGEN) controls the following:

- Implementing the IVA2.2 idle handshake protocol with the PRCM
- Resynchronizing interrupts and DMA requests from device peripherals external to the IVA2.2 subsystem
- Blocking the interrupts and DMA requests to the IVA2.2 on clean boundaries, when the WUGEN is asked to go into IDLE state
- Detecting the enabled wake-up interrupts and DMA requests and generating a wake-up event to the PRCM
- Formatting interrupts to DSP megamodule interrupt format

Figure 5-19 shows the WUGEN in the IVA2.2 subsystem and its interactions with other submodules.

Figure 5-19. IVA2.2 WUGEN Description



5.3.6.1 Interrupts, DMA Requests, and Event Management

Interrupts and DMA requests are generated the same way in the WUGEN module. In this section, both are called events.

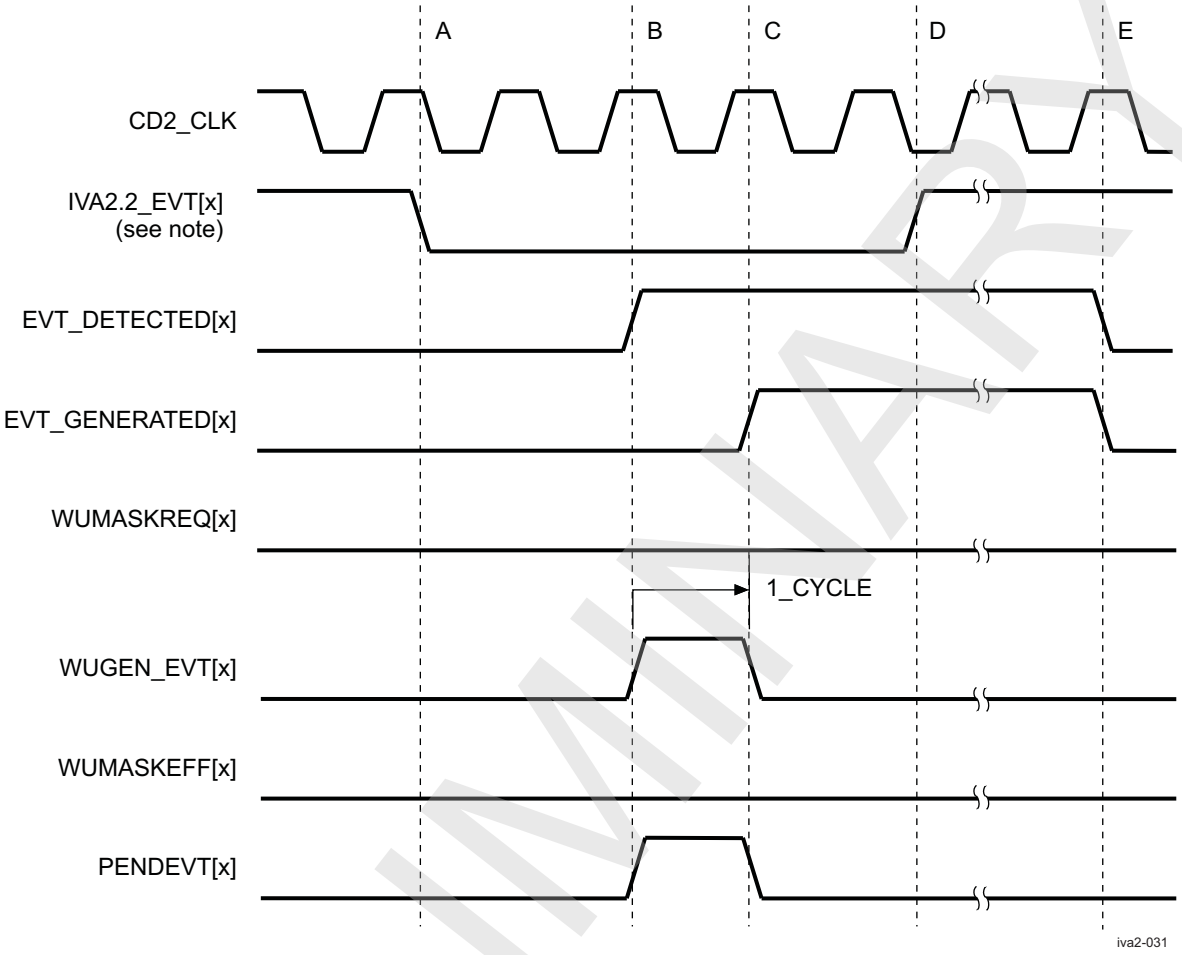
To manage interrupts, DMA requests, and slave port accesses from external modules, the WUGEN module uses several sets of user-programmable registers:

- The WUGEN_MEVT0, WUGEN_MEVT1, and WUGEN_MEVT2 registers define individual mask bits for external asynchronous events (interrupts, DMA requests, slave port access). This register is read-only, only by the DSP. To modify the value of the individual mask, write 1 to the associated bits of WUGEN_MEVTCLR0, WUGEN_MEVTCLR1, and WUGEN_MEVTCLR2 (to clear) and WUGEN_MEVTSET0, WUGEN_MEVTSET1, and WUGEN_MEVTSET2 (to set).
- The WUGEN_PENDEVT0, WUGEN_PENDEVT1, and WUGEN_PENDEVT2 registers are read-only registers that track which external events are pending in the WUGEN module and are not yet generated to the DSP megamodule interrupt controller (INTC) or to the EDMA. If an event is masked, this information is stable until the corresponding mask bit is cleared. If an event is unmasked, this information may not be stable, and therefore corresponds to a transitive period of processing the event in the WUGEN module.

5.3.6.1.1 Event Generation

Figure 5-20 shows event-generation steps in the WUGEN.

Figure 5-20. WUGEN Event Generation



NOTE: IVA2.2_EVT[x] refers to either IVA2.2nIRQ[x] or IVA2.2_nDMAREQ[x].

(A) An asynchronous event is asserted.

(B) The event is resynchronized and detected. Because the event is not masked, it is propagated to DSP megamodule/EDMA.

(C) The event-pending flag is cleared because the event was generated. The event to DSP megamodule/EDMA is deasserted after one WUGEN clock cycle.

(D) After some time, the source of the event is released (probably because it cleared in the corresponding interrupt status register).

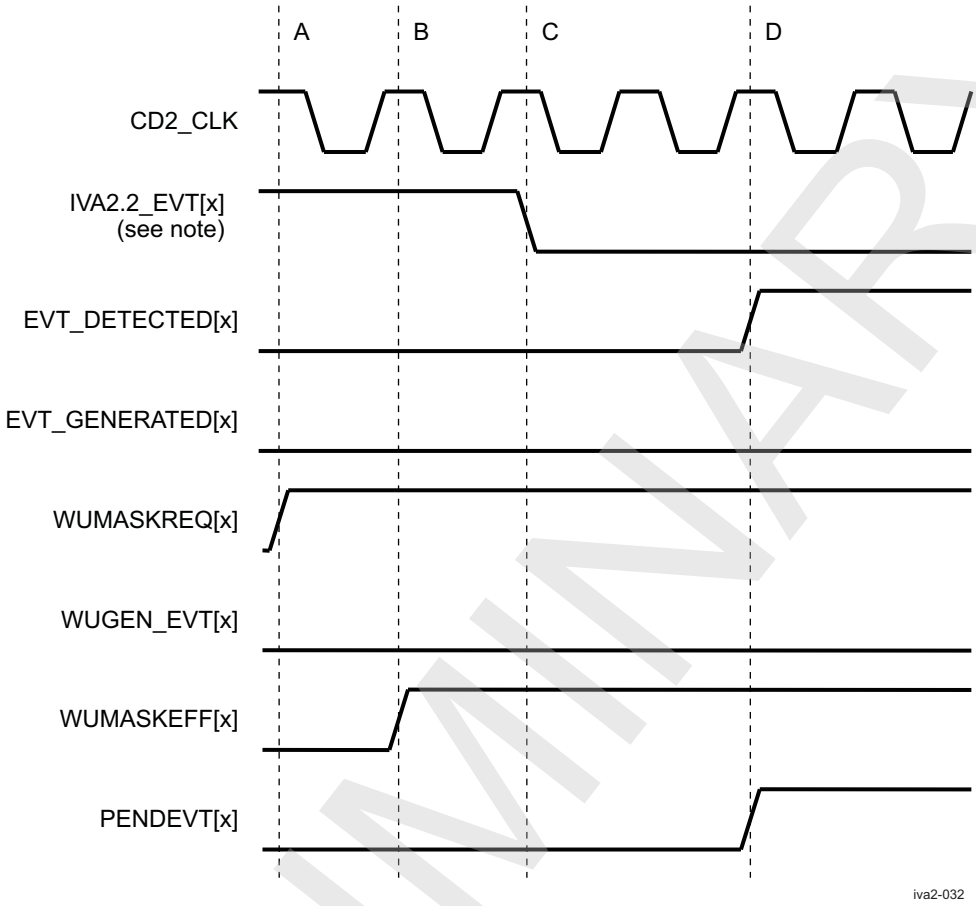
(E) The release of the event is detected and clears the internal EVT_GENERATED flag for that interrupt.

5.3.6.1.2 Individual Event Masking

To mask individual events, write 1 in the WUGEN_MEVTSET0, WUGEN_MEVTSET1, or WUGEN_MEVTSET2 register of the WUGEN module. These registers are used to mask interrupts and DMA requests.

Figure 5-21 shows the mechanism of event masking in the WUGEN module.

Figure 5-21. WUGEN Event Masking



NOTE: IVA2.2_EVT[x] refers to either IVA2.2_nIRQ[x] or IVA2.2_nDMAREQ[x].

(A) The user sets the corresponding bit in the mask. Event generation is disabled.

(B) Event mask completion is reflected in the IVA2.2.WUGEN_MEVT0 to IVA2.2.WUGEN_MEVT2 registers (where i = 0 to 2) for reads.

(C) An asynchronous event is asserted.

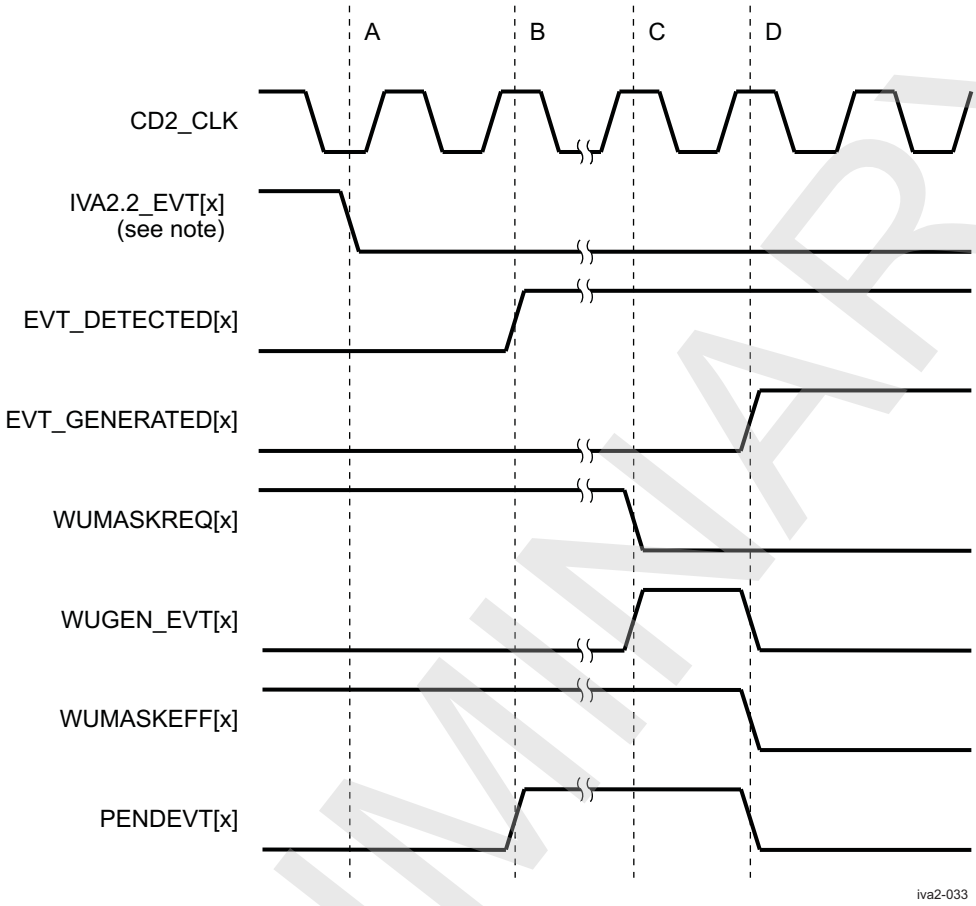
(D) The event is resynchronized and detected. Because the event is masked, it is not propagated to DSP megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.

5.3.6.1.3 Individual Event Mask Clear

To unmask individual events, write 1 in the WUGEN_MEVTCLR0, WUGEN_MEVTCLR1, or WUGEN_MEVTCLR2 register of the WUGEN module.

Figure 5-22 shows the event-mask-clear mechanism in the WUGEN module.

Figure 5-22. WUGEN Event Mask Clear



NOTE: IVA2.2_EVT[x] refers to either IVA2.2_nIRQ[x] or IVA2.2_nDMAREQ[x].

(A) An asynchronous event is asserted.

(B) The event is resynchronized and detected. Because the event is masked, it is not propagated to DSP megamodule/EDMA. The event-pending flag is kept active (sticky) until the mask is removed.

(C) After some time, clear the corresponding bit in the WUGEN mask. The event is automatically generated to DSP megamodule if the event is still seen as active. If the event is not seen as active, nothing happens.

(D) In both cases, the event-pending flag is cleared.

For more information about interrupts and the EDMA programming model, see Section 5.4.8, *Interrupt Management*, and Section 5.4.4.1, *Transfers From/to Device Memories/Peripherals (EDMA)*.

5.3.6.2 Idle Handshake

After reset, the WUGEN waits for a request. If the user executes the DSP IDLE instruction to put the DSP in standby state, the SYSC initiates a clock-off handshake with the WUGEN.

5.3.7 SYSC Module

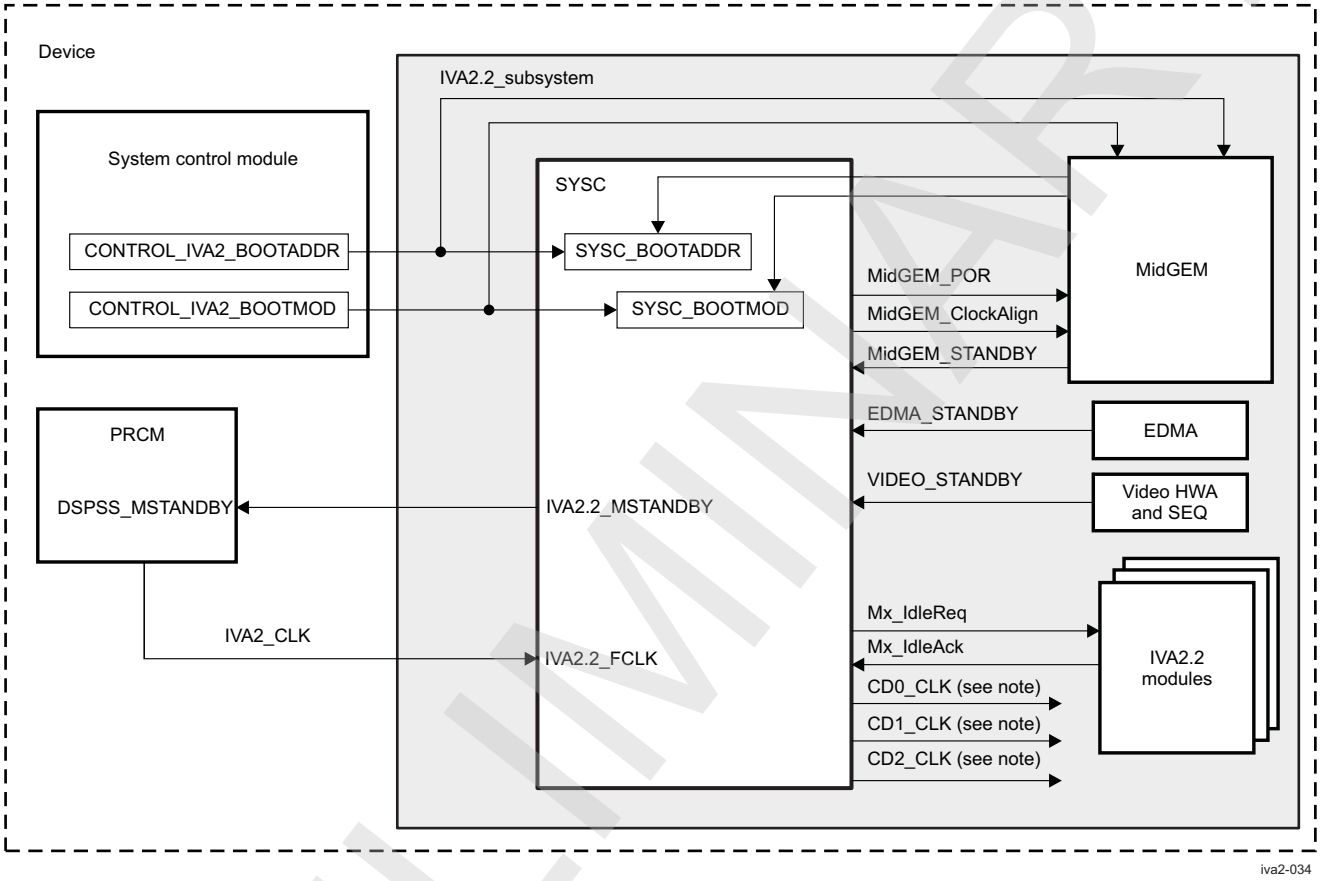
The SYSC module of the IVA2.2 subsystem controls the following functions:

- Generation of the divided clocks to all components of the IVA2.2 subsystem
- Synchronization of the IVA2.2 divided clocks and the DSP megamodule internal-divided clocks
- PRCM power handshaking

- Sequencing of clock-to-off transition for the IVA2.2 modules
- Reset input resynchronization of the active-to-nonactive transition to the CD2_CLK clock
- IVA2.2 boot configuration and its access from the DSP

Figure 5-23 is the block diagram of the SYSC in the IVA2.2 subsystem.

Figure 5-23. SYSC Block Diagram



NOTE: For more information, see Section 5.2.1, *Clocking, Reset, and Power-Management Scheme*.

5.3.7.1 Divided Clock Generation

The SYSC module generates the divided clocks used by the modules in the IVA2.2 subsystem. The SYSC generates three clocks:

- CD0_CLK
- CD1_CLK
- CD2_CLK

Based on the IVA2.2_FCLK clock, these three clocks are configured from the PRCM. For details, see Section 5.2.1, *Clocking, Reset, and Power-Management Scheme.*

5.3.7.2 Clock Management, Power-Down, and Wake-Up

The SYSC ensures correct generation of the clocks described in Figure 5-23. The SYSC also allows management of the clock gating of the EDMA, video accelerator, sequencer, and DSP megamodule if the user wants to lead some dynamic power aspects.

The SYSC module controls the transition to IVA2.2 subsystem standby state and standby signal

generation (IVA2.2_MSTANDBY signal in Figure 5-23) to the PCRM. Using the signals DSP_MEGACELL_STANDBY, EDMA_STANDBY, VIDEO_STANDBY, Mx_IdleReq, and Mx_IdleAck, the SYSC manages and controls the correct power-down transition of the IVA2.2 subsystem and its submodules to ensure that the IVA2.2 internal clocks can be cut. For information about the IVA2.2 power-down transition and its programming model, see Section 5.4.10.3, *Power-Down and Wake-Up Management*.

External events can also occur at the IVA2.2 boundary (access to IVA2.2 using the slave access port or external nonmasked events), requiring the restart of the IVA2.2 clocks (in case of IVA2.2 standby state). The WUGEN module controls the asynchronous generation of a wake-up signal to the PRCM; this signal restarts IVA2.2 PLL clock generation, allowing the SYSC to regenerate the IVA2.2 internal clocks.

5.3.7.3 Boot Configuration

The IVA_SYSC.SYSC_BOOTADDR and IVA_SYSC.SYSC_BOOTMOD registers are the boot-time configuration registers. These read-only registers are accessible only by the DSP, and their values are determined when the IVA2.2 subsystem is released from reset by the PRCM.

The values of these registers are driven externally by two system control module registers, SYSC_GENERAL1.CONTROL_IVA2_BOOTADDR and SYSC_GENERAL1.CONTROL_IVA2_BOOTMOD, which are read-write accessible by the MPU subsystem for MPU-driven IVA2.2 boot sequence and/or by the IVA2.2 DSP for autonomous boot. For more information, see Section 5.4.1 , *IVA2.2 Boot*.

NOTE: If the values of the SYSC_GENERAL1.CONTROL_ IVA2_BOOTADDR and SYSC_GENERAL1.CONTROL_IVA2_BOOTMOD registers change, the new IVA2.2.SYSC_BOOTADDR and IVA2.2.SYSC_BOOTMOD register values are not updated until the next reset.

For more information, see Section 5.4.1, *IVA2.2 Boot*.

5.3.7.4 Interconnect Optimization

The IVA2.2.SYSC_LICFG0 and IVA2.2.SYSC_LICFG1 registers are local interconnect configuration registers. They are read-write accessible by the DSP only. Setting these registers enables or disables interconnect optimization.

5.3.7.5 Video Accelerator/Sequencer SYSC

The video and sequencer system control module (called VIDEOSYSC in Section 5.5.11, *Video System Controller Registers*) controls module reset, power management, and interrupt handling for the video accelerators/sequencer modules.

5.3.7.5.1 Reset

The reset module resynchronizes asynchronous reset for the following modules:

- iVLCD
- iME
- iLF
- SL2IF
- Video and sequencer interconnect
- Sequencer

For details, see Section 5.2, *IVA2.2 Subsystem Integration*.

5.3.7.5.2 Power Management

The video accelerator/sequencer SYSC controls clock gating for the iLF, iME, iVLCD, and sequencer modules and controls clock division for the sequencer module.

The VIDEOSYSC_CLKCTL register is used to stop or restart the module clocks. A write of 1 requests the module logic to go idle and to stop the clock. A write of 0 requests a restart of logic and clock. When a new request or command occurs, a module automatically exits the IDLE state and the clock starts. Clock gating can be controlled for the following modules:

- SL2 memory interface (controlled by the VIDEOSYSC_CLKCTL[5] SL2IFCLKEN bit)
- Sequencer memory and slave port (controlled by the VIDEOSYSC_CLKCTL[4] SEQMEMCLKEN bit)
- iVLCD module (controlled by the VIDEOSYSC_CLKCTL[2] IVLCDCLKEN bit)
- iME module (controlled by the VIDEOSYSC_CLKCTL[1] IMECLKEN bit)
- iLF module (controlled by the VIDEOSYSC_CLKCTL[0] ILFCLKEN bit)

For details, see Section 5.5.11 *Video System Controller Registers*.

The VIDEOSYSC_CLKDIV[1:0] SEQCLKDIV bit field is used to set a clock divider for the sequencer. A divider of 1, 2, 3, or 4 is available. For details, see Section 5.5.11, *Video System Controller Registers*.

5.3.7.5.3 Interrupt Handler

The video accelerator/sequencer SYSC has a single interrupt output, VIDEO_INT, which is an active low-level interrupt connected to the DSP megamodule. Once asserted, it can be cleared explicitly only by software. It can be enabled or disabled by software. It is asserted when one of the enabled event lines gets asserted. Table 5-7 lists these interrupts.

Table 5-7. LSYS Input Interrupts

Nb	Name	Description
7	Reserved	Reserved
6	SEQ_MBX	Sequencer mailbox IRQ
5	DMA_ERROR	DMA error IRQ
4	HOST_ERROR	HOST error IRQ
3	Reserved	Reserved
2	IVLCD	iVLCD IRQ
1	iLF	iLF IRQ
0	iME	iME IRQ

Four registers are defined for IRQ operation:

- The IVA.VIDEOSYSC_IRQSTATE register tracks input events. Each event is associated with a bit in this register. When the bit is set after an active pulse on the associated event line, this bit is kept active (sticky) until the user explicitly writes 1 to that bit.
- The IVA.VIDEOSYSC_IRQMASK register controls the sensitivity of the interrupt line to input events. Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated active event is not allowed to trigger an interrupt. When the user writes 0, the associated active event triggers an interrupt.
- The IVA.VIDEOSYSC_IRQSET register is used to set the interrupt bits (used to test interrupt). Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated event is set in the IVA.VIDEOSYSC_IRQSTATE register. When the user writes 0, there is no effect.
- The IVA.VIDEOSYSC_IRQCLR register is used to clear the interrupt bits in the IVA.VIDEOSYSC_IRQSTATE register. Each event is associated with a bit in this register. When the user writes 1 to a bit, the associated event is cleared in the IVA.VIDEOSYSC_IRQSTATE register. When the user writes 0, there is no effect.

5.3.8 Local Memories

The IVA2.2 subsystem integrates three memory controllers under the control of the DSP megamodule:

- DMC
- PMC
- UMC

Depending on the software configuration of these memory controllers, the IVA2.2 subsystem local memories (ROM and RAMs) can be used as cache or memory-mapped memories.

Figure 5-24 shows the memory hierarchy of the IVA2.2 subsystem.

Figure 5-24. IVA2.2 Local Memories Hierarchy

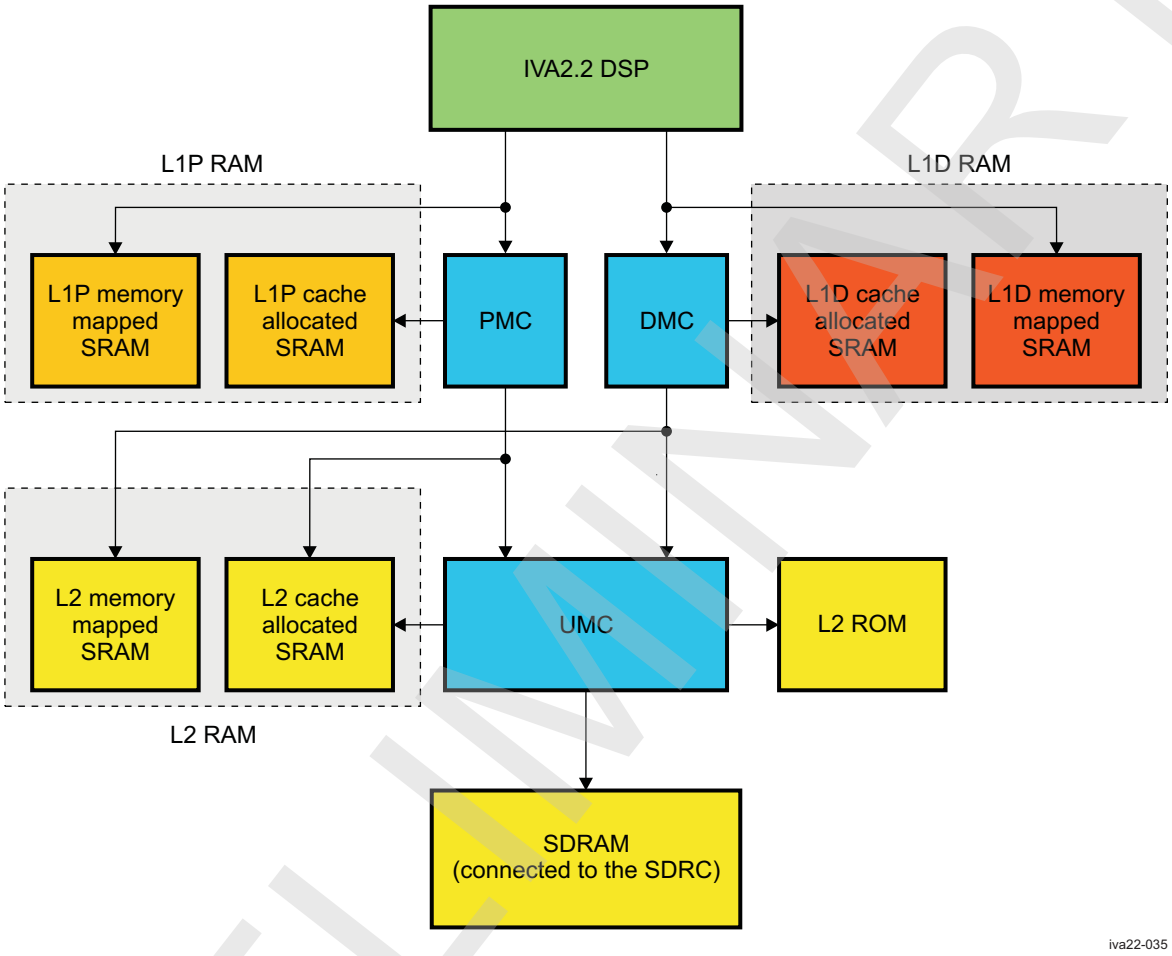


Table 5-8 lists the IVA2.2 DSP megamodule cache controller features.

Table 5-8. IVA2.2 DSP Megamodule Cache Controller Features

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
SIZE	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 4KB, 8KB, 16KB, or 32KB	Programmable to 0KB, 32KB, or 64KB
ASSOCIATIVITY	Direct-mapped	Two-way set associative	Four-way set associative
SRAM MODE [memory-mapped SRAM]	Programmable to 0KB, 16KB, 24KB, 28KB, 32KB [32KB - cache size]	Programmable to 48KB, 64KB, 72KB, 76KB, 80KB [80KB - cache size]	Programmable to 32KB, 64KB, or 96KB [96KB - cache size]
WRITE BUFFER	NR	Yes	Yes
HIT UNDER MISS	Yes	Yes	No
MISS PIPELINING	Yes	Yes	No
REPLACEMENT POLICY	NR	True LRU	True LRU (pseudo-LRU)
CACHEABILITY	Always cached	Programmable	Programmable
BUFFERABILITY	NR	Always buffered	Always buffered
WRITE POLICY	NR	Always write-back	Always write-back
ALLOCATION POLICY	Read-allocate	Read-allocate	Read-write-allocate

Table 5-8. IVA2.2 DSP Megamodule Cache Controller Features (continued)

Cache	L1 Program Cache	L1 Data Cache	L2 Unified Cache
CRITICAL WORD FIRST	No	No	No
CRITICAL LINE FIRST	NR	NR	Yes
ADVANCE FETCH	Yes, because of DSP advanced fetch-and-miss pipelining	NR	NR

5.3.8.1 ROM Overview

The IVA2.2 subsystem contains 16KB L2 ROM. The content of this ROM includes boot code.

For information about boot code and the IVA2.2 boot mechanism, see Section 5.4.1, *IVA2.2 Boot*.

When the L1P SRAM is configured to be inactive (that is, fully memory-mapped SRAM), DSP program fetch accesses to the L2 ROM are realized directly, and thus suffer the L2 latency.

5.3.8.2 RAM Overview

- 32KB L1 program RAM (L1P)
- 80KB L1 data RAM (L1D)
- 96KB L2 unified RAM (L2)

NOTE: The maximum cache size for the PMC is 32KB. L1P memory-mapped RAM can be programmed to allocate 0KB (full-cache), 16KB, 24KB, 28KB, or 32KB (no cache, default) using the PMC registers. The remaining memory is allocated to the cache controller.

The maximum cache size for the DMC is the default 32K bytes. L1D memory-mapped RAM can be programmed to allocate 48KB (full-cache), 64KB, 72KB, 76KB, or 80KB (no cache, default). The remaining memory is allocated to the cache controller (DMC).

L1P and L1D RAM operate at the DSP frequency (CD0 clock domain).

L2 RAM operates at half the DSP frequency (CD1 clock domain).

In the IVA2.2 subsystem, L2 can be configured so that the memory-mapped RAM allocates 32KB, 64KB, or 96KB (no cache) of L2 memory. The remaining memory is allocated to the cache controller

By default, L2 memory is used as 96-KB local memory-mapped RAM. However, L2 RAM is typically used as 64KB allocated to the cache RAM. This is programmable in the DSP megamodule UMC.

The L2 memory-mapped SRAM is shared by the DSP megamodule and the SL2 interface. An arbitration mechanism is implemented for concurrent access, with the DSP megamodule having priority. These last 32KB cannot be used as cache RAM, but only as memory-mapped RAM. Because of address restrictions, the iME and iLF modules can access only the last 32KB of shared L2.

For information about the software programming model for cache management of the local RAM memories of the IVA2.2 subsystem, see Section 5.4.3, *Cache Management*.

5.3.9 Local Interconnect Network

The local interconnect network is the IVA2.2 internal logic that allows internal communication between the modules of the subsystem (for example, the DSP megamodule can communicate with the EDMA or with the WUGEN module). Communication with the rest of the system is through the MMU as master port (accesses from the IVA2.2 subsystem to the L3 interconnect), and through a slave port for accesses from the L3 interconnect (accesses from the L3 interconnect to the IVA2.2 subsystem).

For information about global memory mapping of the IVA2.2 subsystem (DSP CPU view or MPU view through the L3 interconnect), see Chapter 2, *Memory Mapping*.

5.3.9.1 Endianness

The IVA2.2 local interconnect network does not support the big-endian convention or any type of endianness conversion. Only little-endian is supported by the local interconnect network.

5.3.10 Error Reporting

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

The INTC of the DSP megamodule allows reporting of dropped interrupts, through the INTERR signal.

L3 out-of-band errors are also reported through the external L3 interrupt signal. For details about interrupt mapping, see Table 5-3. For information about L3 interconnect error reporting, see Chapter 9, *Interconnect*.

The IDMA and EDMA have their own error-reporting mechanism. Error-status registers and error interrupts inform the user of problems during IVA2.2 internal operation (data error, bus activity error, etc.).

For information about error management and the register set that allows error tracing, see Section 5.4.11, *Error Identification Process*.

5.4 IVA2.2 Subsystem Basic Programming Model

5.4.1 IVA2.2 Boot

The boot-time configuration registers are IVA_SYSC.SYSC_BOOTADDR and IVA_SYSC.SYSC_BOOTMOD. These read-only registers are accessible only by the DSP CPU, and their values are determined when the IVA2.2 is released from reset, using the CONTROL.CONTROL_IVA2_BOOTADDR and CONTROL.CONTROL_IVA2_ BOOTMOD registers of the system control module. For more information, see Chapter 13, *System Control Module*. A change to those registers is not seen (not sampled) by the IVA2.2 until the next reset.

The IVA2.2 boots two ways:

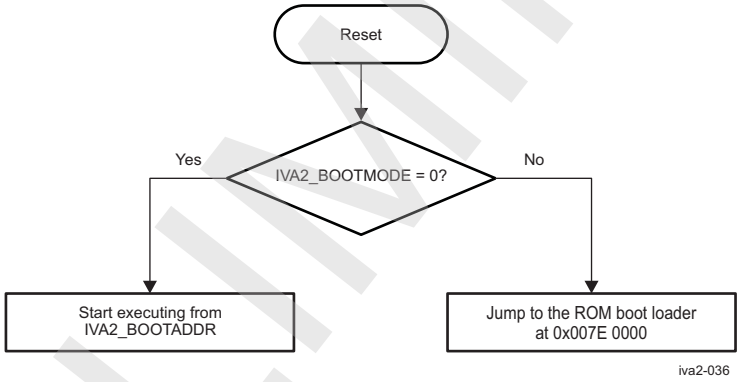
- Boot under MPU control, described in Section 5.4.1.2.1, *Boot Under MPU Control*.
- Autonomous boot, described in Section 5.4.1.2.2, *Autonomous Boot*.

A boot under MPU control is typically used after the device cold reset as a first-time configuration of the IVA2.2 subsystem. Subsequent boots of the IVA2.2, resulting from a wake-up transition from OFF state, for example, use the autonomous boot.

5.4.1.1 IVA2.2 Boot Configuration

Figure 5-25 shows the boot sequence followed by IVA2 on release from reset.

Figure 5-25. IVA2 Boot Mode Configuration



When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BootMode equals 0x0, the first fetch address of the C64x equals the address defined in the CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTLOADADDR bit field. This address can be aligned on any 1-K byte boundary, in ROM, in IVA2.2 local RAM, in on-chip memory (OCM-RAM), or directly in external memory (for example, SDRAM through the SDRC).

When the IVA2.2 subsystem is released from reset and CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BOOTMODE is different from 0x0, the first fetch address of the C64x is fixed to 0x007E0000 (in IVA2.2 local ROM). ROM code boot loader configuration is detailed in Table 5-9.

Table 5-9. Boot Loader Configuration

Value of SYSC_IVA2_BOOTMOD	Description
0x01	IDLE Boot: Boot loader configures the PDCCMD and then executes the IDLE instruction. See Section 5.4.1.1.1.
0x02	Wait in self-loop mode: Boot loader puts IVA2.2 in a self-loop. See Section 5.4.1.1.2.
0x03	Cache Config Mode: Boot loader configures the L1P, L1D, L2 caches and the MAR register. See Section 5.4.1.1.3.
0x04	User defined bootstrap mode: Boot loader copies the boot strap into L2 memory and branches to it. See Section 5.4.1.1.4.
0x05	Reserved.

5.4.1.1.1 IDLE Boot Mode

In this boot mode the PDCCMD register is configured before the IDLE instruction is executed. When the IDLE instruction is executed, if there are no pending requests from either the DMA or an interrupt, IVA goes into sleep mode.

The PDCCMD register is programmed as shown in Table 5-10.

Table 5-10. PDCCMD Programmed Value in IDLE Boot Mode

BitField	Value	Description
GEMPD	1	Sleep mode. Power-down DSP CPU and megamodule when DSP CPU enters IDLE state.
EMCMEM	11	Internal RAMs sleep with retention.
EMCLOG	11	Maximum dynamic clock gating of module regions, with potential : latencies/penalties for wake when megamodule is active and Static clock gating to the EMC when megamodule is in standby.
UMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L2 defined at chip-level.
UMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the UMC when megamodule is in standby.
DMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L1D defined at chip-level.
DMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the DMC when megamodule is in standby
PMCMEM	11	Sleep mode 3. Internal RAMs sleep with retention, L1P defined at chip-level.
PMCLOG	11	Maximum dynamic clock gating of module regions, with potential latencies/penalties for wake when megamodule is active and Static clock gating to the PMC when megamodule is in standby

5.4.1.1.2 Wait in Self Loop Mode

In this mode boot loader puts the IVA2 in a self-loop. The MPU then has the option to download the bootstrap code from the MPU side directly into IVA2 internal memory through Host Port Interface (L3 slave interface). MPU then sets up CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BOOTMODE to '0' and CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTLOADADDR to the internal memory address where it copied the bootstrap, IVA2.2 is then released from reset. Upon completion of the reset sequence IVA2.2 jumps to the bootstrap code loaded by the user in its internal memory and starts executing it.

5.4.1.1.3 Default Config Cache Mode

In this mode the boot loader configures the L1P, L1D, L2 caches and the MAR registers of DSP megamodule. After performing this configuration the boot loader branches to an external memory address. The values with which these settings are done and the external memory address to which the boot loader jumps is specified using a header.

Table 5-11 specifies the format of the header.

Table 5-11. Header Format Used in Defautl Config Cache Mode

Offset from Base Address of Header (in bytes)	Fields Description
0x00	Value of L1PCFG register to be loaded.
0x04	Value of L1DCFG register to be loaded.
0x08	Value of L2CFG register to be loaded.
0x0C	1 -> Set PC bit of all MARi registers to 1 0 -> No action will be taken as by default PC bit of all MARi registers is set to 0
0x10	Address of external memory to which boot loader should branch to.

The address of this table (header) should be specified in the CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTLOADADDR register before IVA2.2 is released from reset.

Setting of the L1PCFG, L1DCFG, and L2CFG is done as follows:

- The desired cache mode is written to the L1PCFG, L1DCFG, and L2CFG.
- L1PCFG, L1DCFG, and L2CFG are read back. This stalls the CPU until the mode change completes

Setting of the MAR registers is done as follows:

- The desired value (in our case 1) is written to the MAR
- The final value written to the MAR address is read back. This stalls the CPU until all the MAR writes are completed.

5.4.1.1.4 User Defined Bootstrap Mode

In this mode the boot loader downloads a user bootstrap code, which is kept in the external memory, into the L2 memory of IVA2.2. After transferring, the boot loader branches to the user bootstrap code. Please note that all sections of the user bootstrap code should fit into L2 memory and no section of the bootstrap code should be mapped to either L1P or L1D memory.

Various parameters that the boot loader needs to transfer the bootstrap code are provided using a user bootstrap header present in the external memory. The CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTLOADADDR is setup with the address of this user bootstrap header before IVA2.2 is released from reset.

Table 5-12 specifies the format of the bootstrap header.

Table 5-12. Header Format Used in User Defined Bootstrap Mode

Offset from Base Address of Header (in bytes)	Fields Description
0x00	Size of the boot strap code in bytes that will be downloaded into internal memory.
0x04	0 -> Use DMA for transferring the bootstrap code 1 -> Use CPU copy for transferring the bootstrap code.
0x08	Value of L2CFG register to be loaded.
0x0C	Absolute address of L2 memory where the boot strap code is to be copied.
0x10	Offset in bytes from the beginning of the bootstrap code where the first executable instruction of the bootstrap is present.
0x14	Absolute address in external memory from where the bootstrap code will be copied.

NOTE: It is mandatory for the user bootstrap code to be a multiple of 4 words on IVA2.2

5.4.1.2 Example of IVA2.2 Boot

5.4.1.2.1 Boot Under MPU Control

Before waking up the IVA2.2 subsystem, the MPU performs the following sequence (also shown in Figure 5-26):

1. The MPU prepares a translation table hierarchy (TTH) in SDRAM at address <TTH Physical Address>. This TTH must contain at least an address translation for the IVA2.2 MMU physical address range.

NOTE: The DSP CPU does not require an address translation for the TTH, as the TTH is under MPU control only. The IVA2.2 DSP CPU is responsible only for saving and restoring an IVA2.2 MMU context that has been programmed by the MPU.

2. The MPU writes a bootstrap sequence in SDRAM at address <BootLoader Physical Address>. This sequence is executable by the DSP CPU and contains only relative address references, so that it is

relocatable without code modification. This sequence must contain at least (in order):

(a) Set the size of the bootstrap code.
(b) Program the IVA2.2 MMU using physical addresses, as described in the following steps.

NOTE: The device has two instances of MMU: camera MMU or MMU1 (used for the camera subsystem) and IVA2.2 MMU or MMU2 (used for the IVA2.2 subsystem). These two instances are programmed by two identical sets of configuration registers. For more information, see Chapter 15, *Memory Management Units*.

3. Programming of the MMU2 is functionally restricted to setting the MMU2.MMU_CNTL[1] MMUENABLE bit, and the TLB misses are served by the MPU-dedicated interrupt service routine (ISR). However, MMU table-walking logic is preferred because the IVA2.2 must be autonomous after the preliminary settings.

   Moreover, it is critical that the duration of the MMU save-and-restore process use a minimum number of cycles, so that address translation for the MMU configuration registers uses a TLB locked entry. For those reasons, it is recommended that the bootstrap follow the MMU initialization sequence:

   (a) Write <TTH physical address>[31:7] to the MMU2.MMU_TTB[31:17] TTBADDRESS bit field.
   (b) Lock the address translation for the MMU configuration registers.
      (i) Write 0x0 to the MMU2.MMU_LOCK[8:4] CURRENTVICTIM bit field.
      (ii) Write <MMU virtual address>[31:12] to the MMU2.MMU_CAM[31:12] VATAG bit field.
      (iii) Write 1 to the MMU2.MMU_CAM[2] V bit.
      (iv) Write 0x2 to the MMU2.MMU_CAM[1:0] PAGESIZE bit field.
      (v) Write <MMU physical address>[31:12] to the MMU2.MMU_RAM[31:12] PHYSICALADDRESS bit field.
      (vi) Write 1 to the MMU2.MMU_LD_TLB[0] LDTLBITEM bit.
      (vii) Write 0x1 to the MMU2.MMU_LOCK[8:4] CURRENTVICTIM bit field.
      (viii) Write 0x1 to the MMU2.MMU_LOCK[14:10] BASEVALUE bit field.
   (c) Write 1 to the MMU2.MMU_CNTL[2] TWLENABLE bit.
   (d) Write 1 to the MMU2.MMU_CNTL[1] MMUENABLE bit.
   (e) Read back the MMU2.MMU_CNTL register to ensure write completion.

   NOTE: This read does not generate a TLB miss, because the address translation for MMU configuration registers is locked in the TLB.

4. The MPU can lock some other TLB entries, define some power-management MMU settings, and/or enable some interrupts.
5. The MPU correctly programs the associated L3 firewall, ensuring that the DSP CPU has read access to the memory area containing the IVA2.2 bootstrap sequence.
6. The MPU programs the associated L3 firewall, ensuring that the DSP CPU has read and write access to the configuration registers of the MMU2.
7. The MPU writes <bootloader physical address> to the CONTROL.CONTROL_IVA2_BOOTADDR[31:10] BOOTADDR bit field and configures the correct CONTROL.CONTROL_IVA2_BOOTMOD[3:0] BOOTMOD bit field nonzero value.

   NOTE: For a detailed description of the system boot registers, see Chapter 13, *System Control Module*.

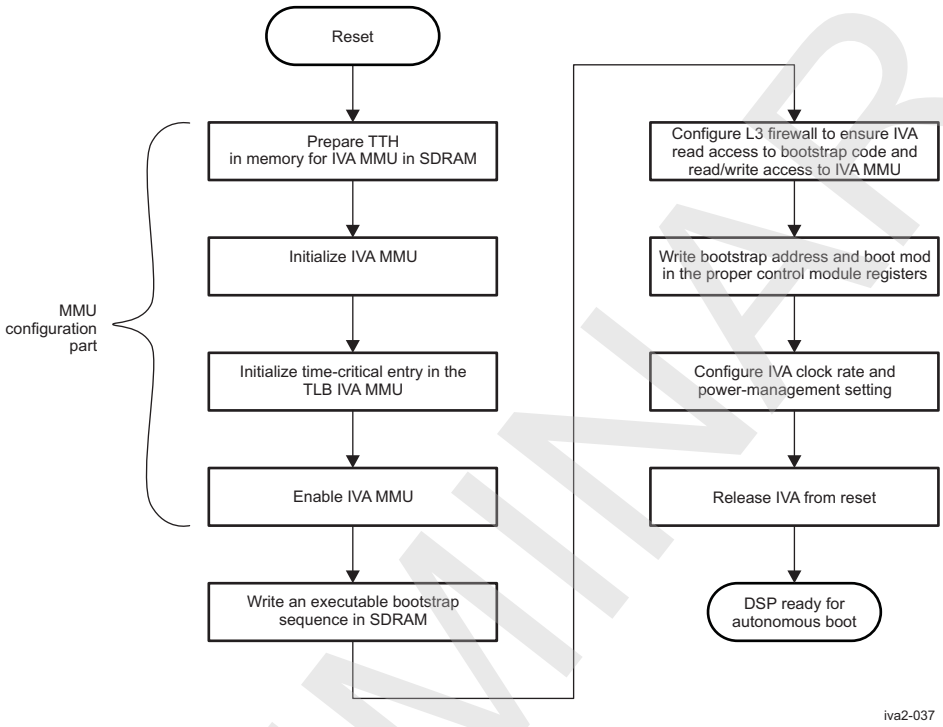
8. The MPU configures the IVA2.2 clock rate and IVA2.2-related power-management settings in the PRCM.

   After initialization completes, the MPU allows the IVA2.2 to boot:

   (a) The MPU releases the IVA2.2 from the OFF state by programming the PRCM.
   (b) The MPU sets the clocks back to the IVA2.2.
   (c) The MPU releases the IVA2.2 from reset.

NOTE: Following Steps 1 through 8, the IVA2.2 boot sequence is identical to the autonomous boot sequence. For information about the IVA2.2 boot sequence, see Section 5.4.1, *IVA2.2 Boot*.

Figure 5-26. IVA2 Boot Basic Programming Model



5.4.1.2.2 Autonomous Boot

On an OFF-to-ACTIVE transition (under MPU control or upon interrupt wakeup), the IVA2.2 subsystem is released from reset.

After hardware configuration of values for DSP megamodule generic parameters, the IVA2.2 starts fetching from the address 0x00000000 in ROM. The IVA2.2 must follow the (nonexhaustive) boot process:

1. Configure memory protection:
   (a) Specify cache RAMs versus IDMA and DMA accesses.
   (b) Define accessible L2 space (static shared L2 with the MPU/LCD).
2. Load the bootstrap code:
   (a) Read the IVA_SYSC.SYSC_BOOTADDR[31:12] BOOTLOADADDR bit field.
   (b) Read the number of bootstrap words <NbOfWords> to transfer in the first word at the address pointed to by BOOTLOADADDR.
   (c) Transfer as many words as defined in <NbOfWords>.
3. Execute the bootstrap code.

NOTE: This prepares the MMU for address translation of external accesses. In the case of a boot upon interrupt wakeup, the MMU is restored to its exact context before the IVA2.2 is shut off, if this context was saved correctly.

Only from this point can the IVA2.2 subsystem work with virtual addresses.

5.4.2 Sequencer Boot/Reset

After the reset input signal is applied to the video accelerator/sequencer, all modules are operational except the sequencer CPU, which is maintained under reset so that the host can initialize some configuration registers and upload some boot code in the ITCM and DTCM memories of the sequencer.

The sequencer reset is connected on IVA2_RST3, and this reset is controlled by the PRCM. The DSP megamodule or the MPU can release the IVA2_RST3 by clearing the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit.

When the sequencer reset (IVA2_RST3) is released, the sequencer starts fetching instructions from ITCM memory, which is initialized by the DSP megamodule or the MPU before the sequencer reset is released. Thus, a classic boot/reset sequence follows the sequence (only the sequencer is under reset; other modules like iME, iVLCD, and iLF are already out of reset):

1. The DSP initializes the ITCM sequencer memory with sequencer code.
2. The DSP initializes the DTCM sequencer memory with sequencer data.
3. The DSP sets the clock divider for the sequencer module in the IVA.VIDEOSYSC_CLKDIV register.
4. The DSP releases the sequencer from reset by clearing the PRCM.RM_RSTCTRL_IVA2[2] RST3_IVA2 bit.

The sequencer is autonomous (no longer under DSP control).

The DSP and the sequencer processor communicate through a message box; two interrupts are provided for this purpose.

NOTE: For more information about sequencer boot/reset, see *ARM968E-S Technical Reference Manual ARM*.

5.4.3 Cache Management

The IVA2.2 subsystem has a 2-level cache-based architecture. Level 1 data memory/cache (L1D) consists of an 80-KB memory space dedicated to data. L1D memory can be configured as mapped memory, cache, or a combination of the two. The level 1 program memory/cache (L1P) consists of a 32-KB memory space dedicated to program instructions. L1P memory can be configured as mapped memory, cache, or a combination of the two. Level 2 memory/cache (L2) consists of a 96-KB memory space shared by program and data space. L2 memory can be configured as mapped memory, cache, or a combination of the two.

Configuration of the allocation of the L1D, L1P, and L2 memories to mapped memory and/or cache is described in Section 5.4.3.1, *Cache-Size Configuration*.

The virtual address space is split into contiguous chunks to configure which parts of the memory are cacheable and not cacheable. Configuration of cacheability is described in Section 5.4.3.3, *Cacheability Settings*.

5.4.3.1 Cache-Size Configuration

Cache-size configuration is controlled by a set of registers: IVA_XMC.L1PCFG, IVA_XMC.L1DCFG, and IVA_XMC.L2CFG, that correspond to the L1P, L1D, and L2 memories, respectively.

The IVA_XMC.L1PCFG register allows the selection of the size of the L1P cache. The user selects the size of the L1P cache by writing the requested mode to the L1PCFG[2:0] L1PMODE bit field.

Table 5-13 lists the valid settings of L1PMODE.

Table 5-13. Cache Size Specified by L1PMODE

L1PCFG[2:0] L1PMODE	Amount of L1P
Setting	Cache
000b	0 KB (default)
001b	4KB

Table 5-13. Cache Size Specified by L1PMODE (continued)

L1PCFG[2:0] L1PMODE	Amount of L1P
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

The IVA_XMC.L1DCFG register allows the selection of the size of the L1D cache. The user selects the size of the L1D cache by writing the requested mode to the L1DCFG[2:0] L1DMODE bit field.

Table 5-14 lists the valid settings of L1DMODE.

Table 5-14. Cache Size Specified by L1DMODE

L1DCFG[2:0] L1DMODE	Amount of L1D
Setting	Cache
000b	0KB (default)
001b	4KB
010b	8KB
011b	16KB
100b	32KB
101b	Not used
110b	Not used
111b	Maximum cache (maps to 32KB)

In the same way, the L2CFG[2:0] L2MODE bit field controls the size of the L2 cache. The user sets the amount of L2 memory mapped as L2 cache by writing the desired cache mode to this bit field.

Table 5-15 shows the valid settings for L2MODE.

Table 5-15. Cache Size Specified by L2MODE

L2CFG[2:0] L2MODE	Amount of L2
Setting	Cache
000b	0KB (default)
001b	32KB
010b	64KB

When programs initiate a cache mode change, the L1D cache must write back and invalidate its current contents without losing data. This ensures that all updated data held in cache is written back, and that no false hits occur because of a change in the interpretation of cache tags. It also ensures that the L1D snoop tag RAM in the UMC stays in sync with L1D.

While the write-back-invalidate is required to ensure correct cache behavior and to ensure that no cached data is lost, it is not sufficient to prevent data loss as a result of portions of L1D RAM becoming cache. To safely change L1D cache modes, applications must adhere to the procedure described in Table 5-16.

Table 5-16. Switching Cache Modes

To switch from	To	The program must perform the following steps:
A mode with no or some cache	A mode with more cache	1: EDMA, IDMA, or copy necessary data out of the affected range of RAM. 2: Write the desired cache mode to the bit field in the configuration cache register (L1DCFG, L1PCFG, and L2CFG). 3: Read back the register to stall the DSP CPU until the mode change completes.

Table 5-16. Switching Cache Modes (continued)

To switch from	To	The program must perform the following steps:
A mode with some cache	A mode with less or no cache	1: Write the desired cache mode to the bit field in the cache configuration register concerned. 2. Read back the register to stall the DSP CPU until the mode change completes.

L1P RAM is typically used as cache RAM, with no local flat RAM (not the default; must be configured by the user).

L1D RAM is typically used as 32KB allocated to the cache RAM and 48KB has local memory-mapped RAM. By default, L2 memory is configured as 0KB allocated to the cache RAM and 96KB as local memory-mapped RAM (see Table 5-17).

Table 5-17. Default Cache Configuration

Memory Type	Memory Size	Default Cache Setting
L1P RAM	32KB	0KB cache
L1D RAM	80KB	0KB cache
L2 RAM	96KB	0KB cache

5.4.3.2 Cache Mode Configuration

The memory cache controllers of the DSP megamodule (L1D, L1P, and L2) offer two additional operating modes: freeze and/or bypass. These modes are set by the L1DCC[2:0] OPER bit field for L1D, the L1PCC[2:0] OPER bit field for L1P, and the L2CFG[4:3] L2CC bit field for L2.

The freeze and bypass modes affect the operation of only the cache section (no impact on the memory-mapped section of the memory) of each memory controller.

This feature allows real-time applications to limit the amount of data evicted from cache controllers, such as interrupt handlers, during various sections of code.

Table 5-18 summarizes the freeze and bypass modes for each cache controller (set through the OPER field in the L1PCC register for the L1P cache controller, the OPER field in the L1DCC register, and the L2CC field of the L2CFG register for the L2 cache controller).

Table 5-18. Cache Mode Configuration

Cache Controller	Operation Mode		
	Normal	Freeze	Bypass
L1P	Cache operates normally. Read hits return data from the cache. Write hits update the cached data for the cache line.	The L1P cache does not allocate new cache lines on read misses, nor does it cause existing cache contents to be marked invalid. Write misses are dropped. The L1P cache responds normally to program-initiated cache controls (invalidate, mode change).	N/A
L1D	Cache operates normally.	The L1D cache does not allocate new cache lines on read misses, nor does it evict existing cache contents. The L1D cache responds normally to program-initiated cache commands (invalidate, write-back-invalidate mode change).	N/A

Table 5-18. Cache Mode Configuration (continued)

Cache Controller	Operation Mode		
	Normal	**Freeze**	**Bypass**
L2	Cache operates normally.	Cache frozen. Hits proceed normally. L2 sends read and write misses directly to external memory, as if the L2 cache is not present. The L2 does not allocate a new cache line while frozen. Lines can be evicted from L2 only during freeze mode by program-initiated cache coherence operations.	Cache disabled, although internal cache state is retained. When in bypass mode, the L2 cache responds to neither reads nor writes. All requests for external addresses are sent externally. L2 does not update its contents in this mode. As with freeze mode, L2 evicts lines from L2 only during bypass mode as a result of program-initiated cache coherence operations.

5.4.3.3 Cacheability Settings

The address space of the IVA2.2 subsystem is split into contiguous regions of 16M bytes each. Each region has a cacheable attribute that defines whether a reference to a location belonging to the associated memory region must be sent directly to the memory (with exact size and occurrence as requested by the CPU) or must induce a cache line refill and potentially an eviction of another cache line.

The UMC contains registers that control whether certain ranges of memory are cacheable, and whether one or more requestors is allowed access to these ranges.

5.4.3.4 Coherence Maintenance

5.4.3.4.1 Memory-Mapped L1P and L1D Coherence

L1D and L1P are never cached, so there is no coherence maintenance for those memories.

5.4.3.4.2 Memory-Mapped L2 Coherence

Coherence is maintained by hardware between L1D cache content and the L2 memory-mapped memory region.

An L2 reference from the DSP CPU updating an L1D cache location is automatically made visible to the DMA and any master processor on the device with access to the DSP megamodule memory-mapped L2 through the IVA2.2 slave port.

An L2 reference from the DMA and any other master processor on the device with access to the DSP megamodule memory-mapped L2 through the IVA2.2 subsystem slave port is automatically made visible to the DSP CPU through the L1D cache, if it is holding the associated cache line.

NOTE: To reduce the complexity of the L1P cache controller to the L2 controller interface, the L1P cache coherency protocol is removed. This means that coherency between L2 cache and L1P cache is not maintained. On the C64x+ CPU, writes to L2 do not invalidate the corresponding region in L1P. This must be done manually.

5.4.3.4.3 Device Memory Coherence

Coherence is not maintained by hardware between the L2 cache (and L1D cache/L1P cache) and device memories (on-chip memories external to the IVA2.2 subsystem and off-chip memories connected to the SDRAM controller and/or general-purpose memory controller [GPMC]). Coherence in this case must be handled by software. The DSP megamodule offers two sets of registers for user-initiated coherence maintenance between DSP local memories and device memories.

Software coherence maintenance must be synchronized in the system (for example, through message passing; for information, see Chapter 14, *Interprocessor Communication*). In the producer/consumer model, the producer sends a completion message to the consumer only after the write is complete in end memory. If the producer has a cache-based architecture, the producer must initiate a write-back and track

for the completion of the write-back sequence in end memory. For a description of how the write-back sequence occurs in the IVA2.2 subsystem, see Section 5.4.3.4.6, *Write-Back Completion*. When the consumer receives the message, if the consumer has a cache-based architecture, updates by the producer must be effectively seen (not a local nonupdated copy). For a description of how the invalidate sequence occurs in the IVA2.2 subsystem, see Section 5.4.3.4.4, *Global Cache Management*.

Two types of cache coherence management are possible:

- Global cache coherence allows the DSP CPU to ensure coherence of the entire cache at once. See Section 5.4.3.4.4, *Global Cache Management*.
- Block cache coherence allows the DSP CPU to ensure coherence of a contiguous region of the virtual address map, restricted in size to only what is needed. See Section 5.4.3.4.5, *Block Cache Management*.

Each management type provides three sets of actions:

- Invalidate ensures that all required lines are made invalid in the cache. After that operation, any update (before invalidate operation) in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill.
- Write-back ensures that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory, so that any local update by the DSP CPU is made visible by an alternate processor/DMA. This applies only to L1D cache and L2 cache, not to L1P cache.
- Write-back and invalidate ensure that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA, and they ensure that all required lines are made invalid in the cache. After that operation, any update in end memory by an alternate processor/DMA is seen by the DSP CPU, forcing a cache line refill. This applies only to L1D cache and L2 cache, not to L1P cache.

5.4.3.4.4 Global Cache Management

This section describes how to invalidate and write back the cache memory

- Global invalidate

  Global invalidate is controlled by the following registers: IVA_XMC.L2INV, IVA_XMC.L1DINV, and IVA_XMC.L1PINV.

  Example of global invalidate:

```
/* ---------------------------------------------------- */
/* Invalidate anything held in cache. */
/* ---------------------------------------------------- */
L2INV = 1;
/* ---------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ---------------------------------------------------- */
while ((L2INV & 1) != 0)
;
```

  L2INV = 0 ensures that L1D cache and L1P cache are also globally invalidated before the L2 cache invalidate process.

- Global write-back

  Global write-back is controlled by the following registers: IVA_XMC.L2WB and IVA_XMC.L1DWB.

  Example of global write-back:

```
/* ---------------------------------------------------- */
/* Write back anything held in cache. */
/* ---------------------------------------------------- */
L2WB = 1;
/* ---------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ---------------------------------------------------- */
while ((L2WB & 1) != 0)
;
```

To ensure write-back completion of a specific buffer (contiguous address range), see Section 5.4.3.4.6, *Write-Back Completion*, for additional programming steps and an example.

- Global write-back and block invalidate

  Global write-back and block invalidate is controlled by the following registers: IVA_XMC.L2WBINV and IVA_XMC.L1DWBINV.

  Example of global write-back and block invalidate:

```
/* ---------------------------------------------------- */
/* Write back and invalidate anything held in cache. */
/* ---------------------------------------------------- */
L2WBINV = 1;
/* ---------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ---------------------------------------------------- */
while ((L2WBINV & 1) != 0)
;
```

  To ensure write-back completion of a specific buffer (contiguous address range), see Section 5.4.3.4.6, *Write-Back Completion*, for additional programming steps and an example.

5.4.3.4.5 Block Cache Management

- Block invalidate

  Block invalidate is controlled by the following registers: IVA_XMC.L2BAR, IVA_XMC.L2IWC, IVA_XMC.L1DIBAR, IVA_XMC.L1DIWC, IVA_XMC.L1PIBAR, and IVA_XMC.L1PIWC.

  Example of block invalidate:

```
/* ---------------------------------------------------- */
/* Write base address of array to Base Address Register. /
/* Then write length of the array, in words, to the Word*/
/* Count register. */
/* ---------------------------------------------------- */
L2IBAR = &array[0];
L2IWC = = sizeof(array) / sizeof(int);
/* . . . */
/* ---------------------------------------------------- */
/* The CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling the CPU minimally. */
/* ---------------------- ------------------------- */
/* . . . */
/* ---------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ---------------------------------------------------- */
while (L2IWC != 0)
;
```

  L2IWC = 0 ensures that L1D cache and L1P cache are also block invalidated before the L2 cache invalidate process.

- Block write-back

  Block write-back is controlled by the following registers: IVA_XMC.L2WBAR, IVA_XMC.L2WWC, IVA_XMC.L1DWBAR, and IVA_XMC.L1DWWC.

  Example of block write-back:

```
/* ---------------------------------------------------- */
/* Write base address of array to Base Address Register.*/
/* Then write length of array, in words, to the Word */
/* Count register. */
/* ---------------------------------------------------- */
L2WBAR = &array[0];
```

```
L2WWC = sizeof(array) / sizeof(int);
/* . . . */
/* ------------------------------------------------- */
/* CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling CPU minimally. */
/* ------------------------------------------------- */
/* . . . */
/* ------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ------------------------------------------------- */
while (L2WWC != 0)
;
```

To ensure write-back completion of a specific buffer (contiguous address range), see Section 5.4.3.4.6, *Write-Back Completion*, for additional programming steps and an example.

- Block write-back and invalidate

  Block write-back and invalidate is controlled by the following registers: IVA_XMC.L2WIBAR, IVA_XMC.L2WIWC, IVA_XMC.L1DWIBAR, and IVA_XMC.L1DWIWC.

  Example of block write-back and invalidate:

```
/* ------------------------------------------------- */
/* Write base address of array to Base Address Register.*/
/* Then write length of array, in words, to the Word */
/* Count register. */
/* ------------------------------------------------- */
L2WIBAR = &array[0];
L2WIWC = (array) / sizeof(int);
/* . . . */
/* ------------------------------------------------- */
/*The CPU can execute other code here. Block cache operations proceed in parallel with CPU
execution, stalling the CPU minimally. */
/* ------------------------------------------------- */
/* . . . */
/* ------------------------------------------------- */
/* Now, spin waiting for operation to complete. */
/* ------------------------------------------------- */
while (L2WIWC != 0)
;
```

  To ensure write-back completion of a specific buffer (contiguous address range), see Section 5.4.3.4.6 for additional programming steps and an example.

5.4.3.4.6 Write-Back Completion

The SYSC_LICFG0[15] GEMTRUECOMPEN bit must be set to 1 before any DSP CPU C64x+ write for which completion must be ensured. This applies to writes to noncacheable regions and to cache-line write-back completions. By default, SYSC_LICFG0[15] GEMTRUECOMPEN = 0. This default is recommended, to statically set that bit (unless the user wants to locally send a large number of writes to a noncacheable memory region):

- SYSC_LICFG0.GEMTRUECOMPEN = 1;

  Polling on the L*WWC (resp. L*WIWC) ensures that the block write-back operation (and associated invalidate, when applicable) was completely issued by the associated cache controller, but does not ensure that the write-back is effective in end memory.

  To get completion of the write-back of a specific buffer after block or global cache write-back, the user must read back from a noncacheable region of the same L3 or L4 target as the buffer (if data is written in external DDR memory, the read access can be on an SDRC register). The C64x + is uninstalled only after the read following the write-back is complete.

In the producer/consumer model, the cache-based producer typically ensures that the produced buffer is visible to the consumer of that buffer by writing back the address range of that buffer and checking for completion of the write-back sequence before sending a completion message to the consumer.

Example:

```
/* ---------------------------------------------------- */
/* nonCachedArea to be linked to non-cached SDRAM region*/
/* ---------------------------------------------------- */
#pragma DATA_SECTION(nonCachedDummyVar, ".nonCachedArea")
volatile int nonCachedDummyVar;
/* ---------------------------------------------------- */
/* outBuffer is produced buffer in SDRAM to be visible to the consumer */
/* ---------------------------------------------------- */
L2WBAR = &outBuffer[0];
L2WWC = sizeof(outBuffer) / sizeof(int);
/* ---------------------------------------------------- */
/* L2WWC ensures the sequence is completed by the cache controller but not completed in end
memory */
/* ---------------------------------------------------- */
while (L2WWC != 0)
;
/* ---------------------------------------------------- */
/*C64x+ is stalled until dummy memory read has completed which the hardware ensures happens after
write-back of outBuffer completed in SDRAM. */
/* ---------------------------------------------------- */
int dummyRead = nonCachedDummyVar;
/* ---------------------------------------------------- */
/* Then C64x SW (producer) can send message to consumer */
/* ---------------------------------------------------- */
```

- sendCompletionMsgToConsumer();

NOTE: To ensure completion, the nonCachedDummyVar must be in the same target as the written-back buffer.

In the case of the C64x writing in the noncache area: To ensure the completion of the C64x write in physical end memory, set the SYSC_LICFG0 [15] GEMTRUECOMPEN bit to 1 and also read back after the last C64x write.

1. DSP write and DMA read
   The user writes to some noncache region with DSP and then reads from the same area with DMA. To ensure completion of the DSP write in physical end memory, set the SYSC.LICFG0[15] GEMTRUECOMPEN bit to 1 and also read back after the last DSP write. The sequence is:

   (a) Set the SYSC_LICFG0[15] GEMTRUECOMPEN bit to 1.
   (b) DSP writes data in external memory, noncache area.
   (c) DSP reads data in external memory, noncache area: last write data for instance.
   (d) DMA reads data from external memory.

2. DMA write and DSP read
   The opposite of 1. To ensure the completion of DMA write in physical end memory, set the SYSC_LICFG0 DMATRUECOMPEN bit to 1 and PARAM [LCHi].OPT.TCCMODE to 0 (no early completion). The sequence is:

   (a) Set the SYSC_LICFG0.DMATRUECOMPEN bit to 1.
   (b) Set PARAM[LCHi].OPT.TCCMODE to 0.
   (c) Set PARAM[LCHi].OPT.TCCMODE to 0.
   (d) DSP waits for end of DMA transferred:

   - IPR/IPRH bit update (for polling-scheme)
   - Interrupt generation (for interrupt-scheme)
   - CER/CERH bit update (for chaining)

- DSP reads data from external memory.

5.4.3.4.7 Performance Consideration Timing

Long burst is key to improving the efficiency of the SDRAM and reducing cache-line refill and cache-line write-back latencies. The IVA2.2 subsystem allows for improving the burst generation over the device interconnect. This is configurable with the SYSC_LICFG0[16].GEMBURSTOPTEN bit. By default, SYSC_LICFG0[16] GEMBURSTOPTEN = 0, and the burst optimization is disabled. This default is recommended to statically set the bit:

SYSC_LICFG0.GEMBURSTOPTEN = 1

5.4.4 DMA Management

5.4.4.1 Transfers From/to Device Memories/Peripherals (EDMA)

The EDMA optimizes transfers from/to the DSP megamodule (memory-mapped) memories to/from device on-chip and off-chip memories.

The EDMA can perform transfers from IVA2.2 internal memories to IVA2.2 internal memories, but it is not designed for that purpose. The IDMA is recommended in that case (unless a 2-dimensional transfer is required).

The EDMA can perform transfers from device memories/peripherals to device memories/peripherals, but it is not designed for that purpose. The sDMA is recommended in that case. For more information, see Chapter 11, *DMA*.

5.4.4.2 Internal Memory-to-Memory Transfer (IDMA)

The user can quickly page memory regions or fill a memory region of the DSP megamodule memories by using channel 1 of the IDMA module (internal to the DSP megamodule).

The IDMA.IDMA1_COUNT[16] FILL bit defines whether this is a transfer from memory to memory or if this is a solid-color fill.

An IDMA1 transfer where iDMA.IDMA1_COUNT[16] FILL = 0 copies IDMA.IDMA1_COUNT[15:2] COUNT bytes from the address defined in the IDMA.IDMA1_SOURCE register to the address defined in the IDMA.IDMA1_DEST register. The addresses must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The IDMA.IDMA1_COUNT[28] INT register bit enables the IDMA_INT1 interrupt (Evt 14; for information about generation on completion of the IDMA1 transfer, see Table 5-3). By default, no interrupt is generated.

When conflicts occur, the IDMA.IDMA1_COUNT[31:29] PRI bit field defines the priority of the IDMA transfer with respect to DSP and DMA/HOST accesses.

The memory paging programming example follows:

- IDMA1_SOURCE = &mySrcTable[0]; // mySrcTable aligned on word boundary
- IDMA1_DEST = &myDstTable[0]; // myDstTable aligned on word boundary
- IDMA1_COUNT = (IDMA1_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1_COUNT = (IDMA1_COUNT & ~(116)) | 016; // copy mode
- IDMA1_COUNT = (IDMA1_COUNT & ~(128)) | 028; // no interrupt
- IDMA1_COUNT = (IDMA1_COUNT & ~(0x729)) | 0x729; // low priority

An IDMA1 transfer where iDMA.IDMA1_COUNT[16] FILL = 1 replicates the IDMA.IDMA1_SOURCE word as many times as defined in IDMA. An IDMA1_COUNT.COUNT (count divided by 4) to the address defined in the IDMA.IDMA1_DEST destination address must be aligned on word (4-byte) boundaries. The byte count must be a multiple of 4 bytes.

The solid-color copy (SSC) programming example follows:

- IDMA1_SOURCE = my32bPattern; // 32b pattern to be replicated
- IDMA1_DEST = &myDstTable[0]; // myDstTable aligned on word boundary

- IDMA1_COUNT = (IDMA1_COUNT & ~(0xFFFC)) | size of (mySrcTable);
- IDMA1_COUNT = (IDMA1_COUNT & ~(116)) | 116; // SCC mode
- IDMA1_COUNT = (IDMA1_COUNT & ~(128)) | 028; // no interrupt
- IDMA1_COUNT = (IDMA1_COUNT & ~(0x729)) | 0x729; // low priority

NOTE: Because the IVA2.2 subsystem is typically configured (recommended for video applications) so that L1D has memory-mapped SRAM, IDMA1 is normally used only for L1D>L1D fast copy.

5.4.4.3 Programming an EDMA Transfer

Programming a complete EDMA transfer requires the following steps:

1. Define the logical channel(s).
2. Prioritize the defined transfer (with respect to other defined transfers).
3. Start the transfer.
4. Review the progression and completion of the transfer.

5.4.4.4 Defining a Logical Channel

5.4.4.4.1 Single Logical Channel Definition

A complete EDMA transfer can be defined by one or several chained and/or linked logical channels.

Up to 128 independent contexts, each fully defining a logical channel, can be defined. These 128 contexts correspond to the 128 PaRAM entries available in the IVA2.2 subsystem. For more information about these PaRAM entries, see Section 5.3.2.1.1.3, *DMA/QDMA Channel Mapping and PaRAM Entry*, and the corresponding Figure 5-13.

Logical channel definition relies on the following:

- Base addresses:
  - PARAM[LCH#].SRCi: 32-bit source address
  - PARAM[LCH#].DSTi: 32-bit destination address
- Transfer sizes:
  Transfer size is common to source and destination. A transfer can be constituted on a 3-dimensional array; C is an array of CCNT arrays, each composed of BCNT arrays, each composed of ACNT bytes:
  - PARAM[LCH#].ACNT: Number of bytes in the A array (from 0 to 65,535)
  - PARAM[LCH#].BCNT: Number of A arrays in the B array (from 0 to 65,535)
  - PARAM[LCH#].CCNT: Number of B arrays in the C array (from 0 to 65,535)

    NOTE: Setting one of the ACNT, BCNT, or CCNT arrays to 0x0 prevents a transfer from being submitted to one of the physical channels (assuming that the compatibility mode is not set).

  - PARAM[LCH#].BCNTRLD: BCNT reload value when BCNT reaches 0 (from 0 to 65,535)

    NOTE: When programming CCNT>1, programming PARAM[LCH#].BCNTRLD to be equal to PARAM[LCH#].BCNT is recommended.

- Indexes between dimensions:
  - PARAM[LCH#].SRCBIDX: Index between A arrays at source (from -32,768 to 32,767)
  - PARAM[LCH#].SCRCIDX: Index between B arrays at source (from -32,768 to 32,767)
  - PARAM[LCH#].DSTBIDX: Index between A arrays at destination (from -32,768 to 32,767)
  - PARAM[LCH#].DSTCIDX: Index between B arrays at destination (from -32,768 to 32,767)

NOTE: Programming the logical channel does not automatically start it. See Section 5.4.4.6.1, *Assigning a Logical Channel to a Trigger Event.*

- Addressing modes:
  - PARAM[LCH#].OPT[0] SAM: source addressing mode (0: post-incremented; 1: constant)
  - PARAM[LCH#].OPT[1] DAM: destination addressing mode (0: post-incremented; 1: constant)

NOTE: Constant addressing mode is supported only from/to IVA2.2 DSP megamodule memories, not from/to device memories and peripherals. This can be replaced by using a post-increment addressing mode and an index equal to 0.

Example:

```
/* ---------------------------------------------------- */
/*fills dstArray with cstValue values (w/o constant AM) */
/* ---------------------------------------------------- */
```

PARAM[LCH#].SRC = &cstValue;

PARAM[LCH#].DST = &dstArray[0];

PARAM[LCH#].ACNT = sizeof(int);

PARAM[LCH#].BCNT = sizeof(dstArray) / sizeof(int);

PARAM[LCH#].CCNT = 1;

PARAM[LCH#].SRCBIDX = 0;

PARAM[LCH#].DSTBIDX = sizeof(int);

PARAM[LCH#].OPT.SAM = 0;

PARAM[LCH#].OPT.DAM = 0;

5.4.4.4.2 Controlling Submission Granularity

The logical channel (when triggered) can split a transfer into several requests submitted to one of the physical channels. The physical channel supports submitted requests of up to two dimensions, meaning that a 3-dimensional transfer is always split into (at least) 2-dimensional transfers. The user can also program the logical channel so that submitted requests are 1-dimensional transfers; for example:

- PARAM[LCH#].SYNCDIM = 0; // submitted transfers are maximum 1D.
- PARAM[LCH#].SYNCDIM = 1; // submitted transfers are maximum 2D.

5.4.4.4.3 Linking to Another Logical Channel

A logical channel can be programmed so that on its completion another context is copied from another logical channel. This is useful because the logical channel is used as a working set during the DMA transfer, meaning that initial context configuration is lost after the associated transfer completes.

- PARAM[LCH#].LINK = linkLCH# << 5

The LINK value is the base address of the linked logical channel context.

When the LINK value is set to 0xFFFF, no context is loaded for that logical channel:

- PARAM[LCH#].LINK = -1

NOTE: Only the context is copied, and the logical channel is not automatically restarted on link. Restarting a logical channel that just received its new context occurs only after a trigger event associated with that logical channel is detected. See Section 5.4.4.6.1, *Assigning a Logical Channel to a Trigger Event*.

5.4.4.4.4 Chaining Logical Channel

A logical channel can be programmed so that on its total or partial completion, another logical channel is started. This is useful for defining a series of transfers with different contexts as a complete DMA transfer. The main advantage is that the overhead to program all the chained transfers is shared among all channels.

- Partial completion chaining

  After the submitted section (see Section 5.4.4.4.2, *Controlling Submission Granularity*) of a logical channel is complete, a programmable completion code is returned. If partial completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See Section 5.4.4.6.1, *Assigning a Logical Channel to a Trigger Event*.

  To chain a logical channel LCHi to LCHj, so that LCHj is automatically started after each LCHi submission to a physical channel has completed:

  – PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: trigger event number
  – PARAM[LCHi].OPT.ITCCHEN = 1
  – DCHMAP[trigEvtx] = LCHj

- Total completion chaining

  After all submitted parts of a logical channel are complete, programmable completion code is returned. If total completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See Section 5.4.4.6.1, *Assigning a Logical Channel to a Trigger Event*.

  For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after LCHi has completed:

  – PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: trigger event number
  – PARAM[LCHi].OPT.TCCHEN = 1
  – DCHMAP[trigEvtx] = LCHj

5.4.4.5 Prioritizing Defined Transfers

5.4.4.5.1 Mapping Between DMA/QDMA Events and Event Queues

The assignment of 64 DMA and 8 QDMA channels to two event queues of the channel controller is achieved by configuring the DMA queue number registers (TPCC_DMAQNUM0 and TPCC_DMAQNUM1) and the QDMA queue number register (IVA_TPCC.QDMAQNUM). When an event is selected for submission, it is queued in the user-defined event queue. This typically defines a 2-level priority preemption scheme, as queues are usually mapped to different transfer controllers.

5.4.4.5.2 Mapping a Queue to a Transfer Controller

Events at the head of an event queue define which logical channel (Param Entry) is selected for submission to the associated physical channel (transfer controller). The association between an event queue and a physical channel can be defined in the TPCC_QUETCMAP register. By default, TPTC0 is associated with event queue 0, and TPTC1 is associated with event queue 1. This mapping is a static decision; it does not change during DMA operation.

NOTE: TPTC0 and TPTC1 are not symmetrical; their numbers are just inverted, compared to the Davinci device. To improve compatibility with Davinci devices, invert the mapping of the event queue to the transfer controller, as shown below:

QUETCMAP = (QUETCMAP & ~0xFF) | 0x10;

Typically, this is used to allow submission-time preemption, so that by example:

- Event queue 0 is used for background, potentially long, not very latency-sensitive, not very critical DMA transfers.
- Event queue 1 is used for short, latency-sensitive, or critical (for example, hardware synchronized) DMA transfers.

5.4.4.5.3 Handling Priority

In IVA2.2 local interconnect arbitration, priority of individual bus requests for a DMA transfer over other DMA- or CPU-initiated bus requests is defined by the event queue to which the event associated with the transfer is submitted. This can be configured per event queue in the TPCC_QUEPRI[2:0] PRIQ0 and TPCC_QUEPRI[6:4] PRIQ1 bit fields. By default, event queues 0 and 1 have the same priority (highest possible priority is 0x0).

CPU bus-requests priority is defined in the IDMA.MDMAARBE[18:16] PRI bit field. By default, the CPU has the lowest possible priority (0x7).

Typically, this is used to allow transfer-time preemption, so that, for example, bus requests associated with event queue 1 are served ahead of event queue 1 or CPU requests.

Example:

- // DMA#0->0x7 (lowest), DMA#1->0x0 (highest), CPU->0x4 (mid)
- QUEPRI = (QUEPRI & ~0xFF) | 0x07;
- MDMAARBE = (QUEPRI & ~(0xF16)) | 0x4 16;

5.4.4.5.4 Aged Priority

To prevent having a DMA request stalled for a very long time, the IVA2.2 implements an aged priority scheme (also referred to as an inversion priority scheme) on the DMA ports to change the priority defined in the TPCC_QUEPRI register. This is done by regularly decreasing the priority level (increasing priority in arbitration) of a stalled request. The interval between two consecutive updates of the priority level is defined in the SYSC_LICFG1 register. By default, the aged priority scheme is disabled (SYSC_LICFG1=0x0), and arbitration priority is dictated by programmed values in QUEPRI and MDMAARBE.

5.4.4.5.5 Optimizing 2D Transfers

IVA2.2 EDMA can be configured so that DMA 2D transfers are optimized, allowing for large bursts to be generated to the SDRAM. This optimization has no effect on transfers issued as 1D transfers to the physical channels. This is recommended to enable that feature when the sources or destinations of the 2D transfers are the VRFB (SDRAM tiling structure).

To fully benefit from the optimization and disable MMU page-crossing checks:

- Large MMU page(s) are defined for the VRFB view(s) (typically 16MB supersection).
- The user software ensures that a 2D transfer does not span MMU large pages.

With the preceding conditions, use the following settings to use the IVA2.2 2D burst optimization:

- IVA_SYSC.SYSC_LICFG0.DMA2DOPTEN = 1
- IVA_SYSC.SYSC_LICFG0.PAGEXINGEN = 1

NOTE: The user software must ensure that a 2D transfer never spans MMU page boundaries. The reason for IVA_SYSC.SYSC_LICFG0.PAGEXINGEN = 1 is to remove the hardware check mechanism of 2D bursts crossing MMU pages. A 2D burst that spans these boundaries can lead to undefined behavior. PAGEXINGEN = 0 prevents such situations through hardware.

5.4.4.6 Starting the Transfer

Before starting the transfer, a trigger event must be associated with the logical channel. Three modes trigger a DMA transfer:

- Manual trigger (software-synchronized transfers)
- Hardware trigger (hardware-synchronized transfers)
- Automatic trigger (automatic on-submission transfer start)

5.4.4.6.1 Assigning a Logical Channel to a Trigger Event

The 64 DMA channels and the 8 QDMA channels can be flexibly mapped to any of the 128 available PaRAM entries (see Figure 5-13).

Any of the 64 DMA channels can be mapped to any of the 128 PaRAM entries through DMA channel-mapping registers TPCC_DCHMAPi (i = 0 to 63).

Any of the 8 QDMA channels can be mapped to any of the 128 PaRAM entries through QDMA channel-mapping registers TPCC_QCHMAPj (j = 0 to 7).

5.4.4.6.2 Manual Trigger (Software-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 63) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers TPCC_DCHMAPi (i = 0 to 63). Then, the user can manually start the transfer (one logical channel or a chained list of logical channels) by writing 1 to the bit in the TPCC_ESR or TPCC_ESRH register associated with the trigger event of the logical channel (or the first logical channel in the chained list).

NOTE: The event does not need to be enabled in the TPCC_EER register to be manually triggered.

Example:

```
/* ------------------------------------------------ */
/*To manually start defined logical channel #0x3, uses event #20 */
/* ------------------------------------------------ */
DCHMAP[20] = (DCHMAP[20] & ~(0x1FF<<5)) | 0x3<<5;
ESR = 1 << 20;
```

5.4.4.6.3 Hardware Trigger (Hardware-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 19) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers TPCC_DCHMAPi (i = 0 to 19). The user can allow this logical channel to be triggered by an associated hardware DMA request by writing 1 in the associated bit of the EER register. The mapping of a hardware DMA request to DMA events is fixed. The mapping of DMA requests to device peripheral sources is listed in Table 5-2 .

Example:

```
/* ------------------------------------------------ */
/* Associate defined logical channel #0x5 to UART3_DMA_TX*/
/* UART3_DMA_TX is DMA request #10 and associated to evt #10 */
/* ------------------------------------------------ */
```

DCHMAP[10] = (DCHMAP[10] & ~(0x1FF<<5)) | 0x5<<5;

5.4.4.6.4 Automatic Trigger (QDMA)

The user can specify a trigger word from among any of the eight 32-bit words of the logical channel context (PaRAM entry) for QDMA. Writing to the trigger word triggers the channel controller of QDMA to issue a transfer request. The trigger word field of the QDMA channel mapping register TPCC_QCHMAPj (where j = {0 to 7}) defines the trigger word for a particular QDMA channel, as shown in Figure 5-13.

This flexibility enables the CPU to selectively modify only the PaRAM entry that requires modification, and thereby trigger the transfer. For example, after a transfer, if only count must change, QCHMAP can be configured so that count is the trigger word, and a write to it automatically triggers the transfer.

Example:

```
/* ------------------------------------------------ */
/* Associate defined logical channel #0x5 to QDMA #1 */
/* ------------------------------------------------ */
```

```
QCHMAP[1] = (QCHMAP[1] & ~(0x1FF<<5)) | 0x5<<5;
/* ---------------------------------------------------- */
/* Define DST parameter (0x3) to be trigger word of LCH */
/* ---------------------------------------------------- */
QCHMAP[1] = (QCHMAP[1] & ~( 0x7<<2)) | 0x3<<2;
```

In addition, the IDMA can be used to offload the CPU of the DMA configuration. See Section 5.4.4.6.5, *Offloaded Configuration (Using IDMA)*.

5.4.4.6.5 Offloaded Configuration (Using IDMA)

The IVA2.2 allows quick programming of DMA transfers by offloading the CPU of most of the DMA transfer issue time. To do so, the user typically maintains a copy of the logical channel contexts (PaRAM entries) in L1D SRAM. A CPU update of a logical channel context is very fast in L1D SRAM. After completing a logical channel context update, the CPU can page the context from L1D to DMA PaRAM entries using another simple DMA, internal-to-DSP megamodule (IDMA). For example:

```
disable_interrupts();
while(IDMA0_STATUS & 0x3);// previous IDMA completion/*
---------------------------------------------------- */
/* Update of logical channels definition table in L1D */
/* ---------------------------------------------------- */
LCTable->OPT = opt;
LCTable->SRC = src;
LCTable->ACNT = num_bytes;
LCTable->BCNT = num_arrays;
LCTable->DST = dst;
LCTable->DSTBIDX = dbidx;
LCTable->SRCBIDX = sbidx;
LCTable->LINK = 0xFFFF;
LCTable->BCNTRLD = bcntrld;
LCTable->DSTCIDX = dcidx;
LCTable->SRCCIDX = scidx;
LCTable->CCNT = num_frames;
/* ---------------------------------------------------- */
/* initiate IDMA transfer */
/* ---------------------------------------------------- */
IDMA0_SOURCE = &LCTable[0];
IDMA0_DEST = &PaRAM[0];
IDMA0_MASK = 0xFFFFFF00;
IDMA0_COUNT = 0x0;
enable_interrupts();
```

5.4.4.6.6 Direct Configuration to Transfer Channel (Not Recommended)

The registers of the physical channels are memory-mapped, primarily to enable, clear, and read status for error interrupts generated by the physical channel. For more information, see Section 5.4.11, *Error Identification Process*.

It is possible to write directly to other control registers of the physical channels and issue a transfer; however, this is not recommended and therefore is not described here.

NOTE: This can work safely only if the DMA controller is not used.

5.4.4.6.7 DMA Completion Mode

The IVA2.2 EDMA defines when a DMA transfer is complete:

- Early completion: All associated transfers were submitted to the physical channel. Early completion does not ensure that transfer is complete in end memory.
  - PARAM[LCHi].OPT.TCCMODE = 1
- True completion: All associated transfers were submitted to the physical channel, and all those transfers are complete, from the physical channel standpoint. True completion ensures that transfer is complete in end memory.
  - SYSC.SYSC_LICFG0.DMATRUECOMPEN = 1; // is statically set.
  - PARAM[LCHi].OPT.TCCMODE = 0

NOTE: TCCMODE = 0 does not ensure that transfer is complete in end memory if DMATRUECOMPEN = 0.

By default, DMATRUECOMPEN = 0. This is recommended to statically set DMATRUECOMPEN.

True completion is typically used when the IVA2.2 DMA is the producer of a buffer shared with another master processor or a DMA (consumer). A completion message is sent to the consumer only after the DMA transfer is complete.

Completion mode affects timing for the following actions:

- IPR/IPRH bit update (for polling scheme)
- Interrupt generation (for interrupt scheme)
- CER/CERH bit update (for chaining)

5.4.4.6.8 Partial Versus Total Completion

DMA can be programmed so that IPR bit update and interrupt generation occur:

- After each submission to the physical channel is complete
- After the last submission to the physical channel is complete

Partial completion interrupt

After the submitted section (see Section 5.4.4.4.2, *Controlling Submission Granularity*) of a logical channel is complete, a programmable completion code is returned. If a partial completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after each LCHi submission to a physical channel is complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.ITCINTEN = 1

Total completion interrupt

After all submitted parts of a logical channel are complete, a programmable completion code is returned. If a total completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is to be set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after all LCHi submissions to a physical channel are complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.TCINTEN = 1

– By polling
– By interrupt

5.4.4.6.9 Tracking DMA Completion

There are two ways to track DMA completion:

- Polling the completion register when the estimated completion time has elapsed
- Enabling completion interrupts

Polling example (total completion)

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does not contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 0<<myTCC
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // poll IPR bit
- while(!(IPR & (1<<myTCC))); // polls for completion

Interrupt example (total completion)

- disable_interrupts()
- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 1<<myTCC
- INTMUX[0] = (INTMUX[0] & ~(0x7F)) | 0x1D; // map CPU it #4
- CPU.IER = (CPU.IER & (1<<4)) | 1<<4; // unmask CPU it #4
- enable_interrupts()
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // this code is interrupted when DMA completes

5.4.4.6.10 DMA Interrupt Service Routine

The channel controller does not generate a new interrupt signal for new pending interrupts if the user did not clear previous pending interrupts. There are two options for constructing an ISR for DMA. The first is to poll all the bits during execution of the ISR, and to clear all enabled bits in an interrupt-pending register by writing to the interrupt-pending clear (ICR/ICRH) register before exiting any ISR. Pseudo-code for this option follows:

1. Enter ISR.
2. Read TPCC_IPR.
3. For the condition set in TPCC_IPR,
   (a) Perform operation as needed.
   (b) Clear bit for serviced INT.
4. Read IPR.
   (a) If TPCC_IPR = 0, exit ISR.
   (b) If TPCC_IPR = 1, go to Step 3.

The second option is to service the ISR and then, before exiting the ISR, to write to the EVAL bit of the IEVAL register. This forces the EDMA channel controller to generate a new interrupt signal if there are still pending interrupts in the interrupt-pending register (IPR/IPRH). Pseudo-code for this ISR option follows:

1. Enter ISR.
2. Read TPCC_IPR.
3. For the condition set in TPCC_IPR,
   (a) Perform operation as needed.
   (b) Clear bit for serviced INT.
4. Read IPR.
   (a) If TPCC_IPR=0, exit ISR.
   (b) If TPCC_IPR=1, set the TPCC_IEVAL.EVAL bit to force triggering a new interrupt.

5.4.4.6.11 Benchmarking

The DMA channel controller monitors the number of event entries in an event queue to determine whether they exceed the user-programmed threshold. The queue threshold for each event queue can be programmed in the TPCC_QWMTHRA and TPCC_QWMTHRB registers. When the number of event entries in an event queue exceeds the user-programmed threshold, a queue threshold error occurs. This error is captured in the THRXCD field of event-queue status register TPCC_QSTATI (I = 0 or 1) and in the QTHRXCDn field in the TPCC_CCERR register.

5.4.5 IVA2.2 Extended Function Interface

This section describes the extended function interface (EFI) signals, timing, and associated instructions. The EFI runs at the CPU clock that allows the transfer of data between the CPU register file and registers at the CPU boundary that are attached to devices outside the CPU. The C64x CPU does not support an EFI. This section applies only to the C64x+ CPU. For information about other C64x+ instructions, see the *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI literature number SPRU732).

5.4.5.1 Overview

The EFI provides hardware support for data and command transfers to registers outside the CPU in multi-CPU devices.

5.4.5.2 C64x+ EFI Instructions

The following instruction can be used to transfer commands by using the EFI:

- EFCMD: Send 10-bit command code

The following instructions can be used to receive data by using the EFI:

- EFRW: Receive word
- EFRDW: Receive double word

The following instructions can be used to transfer data by using the EFI:

- EFSW: Send word
- EFSDW: Send double word

EFCMD ***Send Command to EFI***

Syntax:	EFCMD (.unit) ucst10 .unit = .S1, .S2, .M1, .M2
Compatibility:	C64x+ CPU only
Opcode:	.S Unit

31		29	28	27				23	22				18	17				13	12	11					6	5	4	3	2	1	0
0	0	0	0	dst					src2					0	1	1	0	1	0	1	1	1	1	0	0	1	0	0	0	s	p

Opcode map field used…	For operand type…	Unit
src2	ucst5	.S1,.S2
dst	ucst5	

Opcode: .M Unit

31		29	28	27				23	22				18	17				13	12	11					6	5	4	3	2	1	0
0	0	0	0	dst					src2					1	1	0	1	1	0	0	0	0	0	1	1	1	1	0	0	s	p

Opcode map field used…	For operand type…	Unit
src2	ucst5	.M1,.M2
dst	ucst5	

Description: A 10-bit data value is sent to the EFI. The five most-significant bits (MSBs) of the 10-bit value are taken from dst; the five least-significant bits (LSBs) are taken from src2. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected.

This instruction executes unconditionally; that is, it cannot be predicated. The EFCMD instruction does not use any data path resources. It is available for scheduling purposes on the S or M units. Only one EFCMD instruction can be scheduled per side; the S or M slot on a side can be used, but not both in the same execute packet. If used in an SPLOOP body, the EFCMD instruction occupies an execution slot corresponding to the unit specified.

The 10-bit command is output at the CPU boundary in E2. The ready signal is not sampled in conjunction with the EFCMD instruction.

Execution:

```
if(.S1)      ucst10 → A_EFI_Cmd[9:0]
else if(.S2) ucst10 → B_EFI_Cmd[9:0]
else if(.M1) ucst10 → A_EFI_Cmd[9:0]
else if(.M2) ucst10 → B_EFI_Cmd[9:0]
```

Instruction type: Single-cycle

Delay slots: 0

EFRDW *Receive Double Word From EFI*

Syntax: EFRDW (.unit) dst_o:dst_e

.unit = .S1, .S2

Compatibility: C64x+ CPU only

Opcode:

31		29	28	27				23	22				18	17				13	12	11					6	5	4	3	2	1	0
0	0	0	0	dst					0	0	0	0	0	0	1	1	1	1	0	1	1	1	1	0	0	1	0	0	0	s	p

Opcode map field used…	For operand type…	Unit
dst	dint	.S1,.S2

Description: A 64-bit data value is read from the EFI and is written to the register pair dst_o:dst_e. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected. There is no cross-path capability; A-side receives must go to an A-file register pair, and B-side receives must go to a B-file register pair. This instruction executes unconditionally; that is, it cannot be predicated.

The ready signal is sampled in the DS phase of the EFRDW instruction and will cause the CPU to stall before the EFRDW instruction reaches E1 if the data to be read has not yet been registered in the CPU.

Execution:

```
if(.S1)      A_EFI_Din[63:0] → dst_o:dst_e (A1:A0 – A31:A30)
else // .2   B_EFI_Din[63:0] → dst_o:dst_e (B1:B0 – B31:B30)
```

Instruction type: Single-cycle

Delay slots: 0

See also: EFRW

EFRW *Receive Word From EFI*

Syntax: EFRW (.unit) dst

.unit = .S1, .S2

Compatibility: C64x+ CPU only

Opcode:

31		29	28	27				23	22				18	17				13	12	11					6	5	4	3	2	1	0
0	0	0	0	dst					0	0	0	0	0	0	1	1	1	0	0	1	1	1	1	0	0	1	0	0	0	s	p

Opcode map field used…	For operand type…	Unit
dst	int	.S1,.S2

Description: A 32-bit data value is read from the EFI and is written to dst. There is an A-side EFI and a B-side EFI. The side used is determined by the S unit that is selected. There is no cross-path capability; A-side receives must go to an A-file register pair, and B-side receives must go to a B-file register pair. This instruction executes unconditionally; that is, it cannot be predicated.

The ready signal is sampled in the DS phase of the EFRW instruction and will cause the CPU to stall before the EFRDW instruction reaches E1 if the data to be read has not yet been registered in the CPU.

Execution:

```
if(.S1)      A_EFI_Din[31:0] → dst (A0 – A31)
else // .2   B_EFI_Din[31:0] → dst (B0 – B31)
```

Instruction type: Single-cycle

Delay slots: 0

See also: EFRDW

EFSDW *Send Double Word to EFI*

Syntax: EFSDW (.unit) src1, src2, dst

.unit = .L1, .L2

Compatibility: C64x+ CPU only

Opcode:

31		29	28	27				23	22				18	17				13	12	11					5	4	3	2	1	0
creg			z	dst					src2					src1					x	0	1	1	1	0	1	0	1	1	0	s	p

Opcode map field used…	For operand type…	Unit
src1	int	.L1, .L2
src2	xint	
dst	ucst5	

Description: The registers src1 and src2 are read from the register file and combined to form a 64-bit value that is sent to the EFI with a 5-bit constant taken from dst. The src2 register provides the 32 LSBs, and the src1 register provides the 32 MSBs. There is an A-side EFI and a B-side EFI. The side used is determined by the L unit that is selected.

The data and constant are output at the CPU boundary in E2. The EFI ready signal is sampled in E2 of the EFSDW instruction and will cause the CPU to stall if the signal indicates the buffering external to the CPU is full.

Execution:

```
if(cond)
if(.L1)        src1:src2 → A_EFI_Dout[63:0]
               ucst5 → B_EFI_Scmd[4:0]
else // .L2    src1:src2 → B_EFI_Dout[63:0]
               ucst5 → B_EFI_Scmd[4:0]
else           nop
```

Instruction type: Single-cycle

Delay slots: 0

See also: EFSW

EFSW *Send Word to EFI*

Syntax: EFSW (.unit) src1, dst

.unit = .L1, .L2

Compatibility: C64x+ CPU only

Opcode:

31		29	28	27				23	22				18	17				13	12	11						5	4	3	2	1	0
creg			z	dst					src2					0	1	1	1	1	x	0	0	1	1	0	1	0	1	1	0	s	p

Opcode map field used…	For operand type…	Unit
src2	xint	.L1, .L2
dst	ucst5	

Description: The src2 register is read from the register file and sent to the EFI along with a 5-bit constant taken from dst. There is an A-side EFI and a B-side EFI. The side used is determined by the L unit that is selected.

The data and constant are output at the CPU boundary in E2. The EFI ready signal is sampled in E2 of the EFSW instruction and will cause the CPU to stall if the signal indicates the buffering external to the CPU is full.

Execution:

```
if(cond)
if(.L1)          src2 → A_EFI_Dout[31:0]
                 ucst5 → A_EFI_Scmd[4:0]
else // .L2      src2 → B_EFI_Dout[31:0]
                 ucst5 → B_EFI_Scmd[4:0]
else             nop
```

Instruction type: Single-cycle

Delay slots: 0

See also: EFSDW

5.4.5.3 C64x+ EFI Use in IVA2.2

The following programming model describes how to write and read a register using the EFI. In the context of IVA2.2, only the EFSW, EFRW,and EFSDW instructions are used.

5.4.5.3.1 Read Registers Using the EFI Programming Model

To read a 32-bit value in a video accelerator register using the EFI, the following sequence must be used:

```
EFSW address_32b, opcode_5b
NOP N
EFRW cpu_reg
```

With:

- address_32b is the video accelerator address of the register from which the value must be read.
- opcode_5b is used to code the read operation: 0x02.
- N is the number of cycles to wait data is written in the EFI FIFO. In the context of IVA2.2 N = 0x22.
- Cpu_reg is the 32-bit CPU register where the read value is stored.

NOTE: To avoid handling specific cases of successive read requests, interrupts are disabled between the time the EFSW is issued and the data is retrieved in the DSP register.

NOTE: When it is necessary to read a large number of registers, the two macros that correspond to the two instructions given previously can be used to allow issuing a read request while reading data:

- EFSW address_32b, opcode_5b: IME_SendReadReq(unsigned ime_addr_reg)
- EFRW cpu_reg: IME_ReceiveData()

In that case, there is no need to insert a NOPs instruction between the two EFI commands. Read latency is under CPU control.

5.4.5.3.2 Write Registers Using the EFI Programming Model

To write a 32 bit-value in a video accelerator register using the EFI, the following instruction must be used:
EFSDW value_32b, address_32b, opcode_5b

With:

- The value_32b register contains the 32-bit word to write.
- address_32b is the video accelerator address of the register in which value must be written.
- opcode_5b is used to code the write operation: 0x01.

NOTE: The address is stored in the even 32-bit register of the 64-bit register pair, while value_32b is stored in the odd register (that is, the MSB part).

5.4.6 iME and iLF Basic Programming Model

5.4.6.1 Typical Use

The iME and iLF coprocessors are parallel coprocessors, so they are partially autonomous and provide highly parallel video processing. To use the iME/iLF coprocessor in a video accelerator design, perform the following steps:

Step 1. Initialize the module.

Step 2. Prepare the data to be processed in the shared L2 memory.

Step 3. Prepare the instructions for processing in the L2 memory.

Step 4. Prepare the parameter stack in the L2 memory.

Step 5. Configure the device to generate an interrupt on completion.

Step 6. Write a LoadInstBuf() instruction in the program buffer register (iME_PROGRAMBUFFERLINENLSBi and iME_PROGRAMBUFFERLINENMSBi or iLF_PROGRAMBUFFERLINENLSBi and iLF_PROGRAMBUFFERLINENMSBi) with the address parameter pointing to the instruction in L2 shared memory.

Step 7. Start the coprocessor by writing to START in the iME_COMMANDREG or iLF_COMMANDREG register.

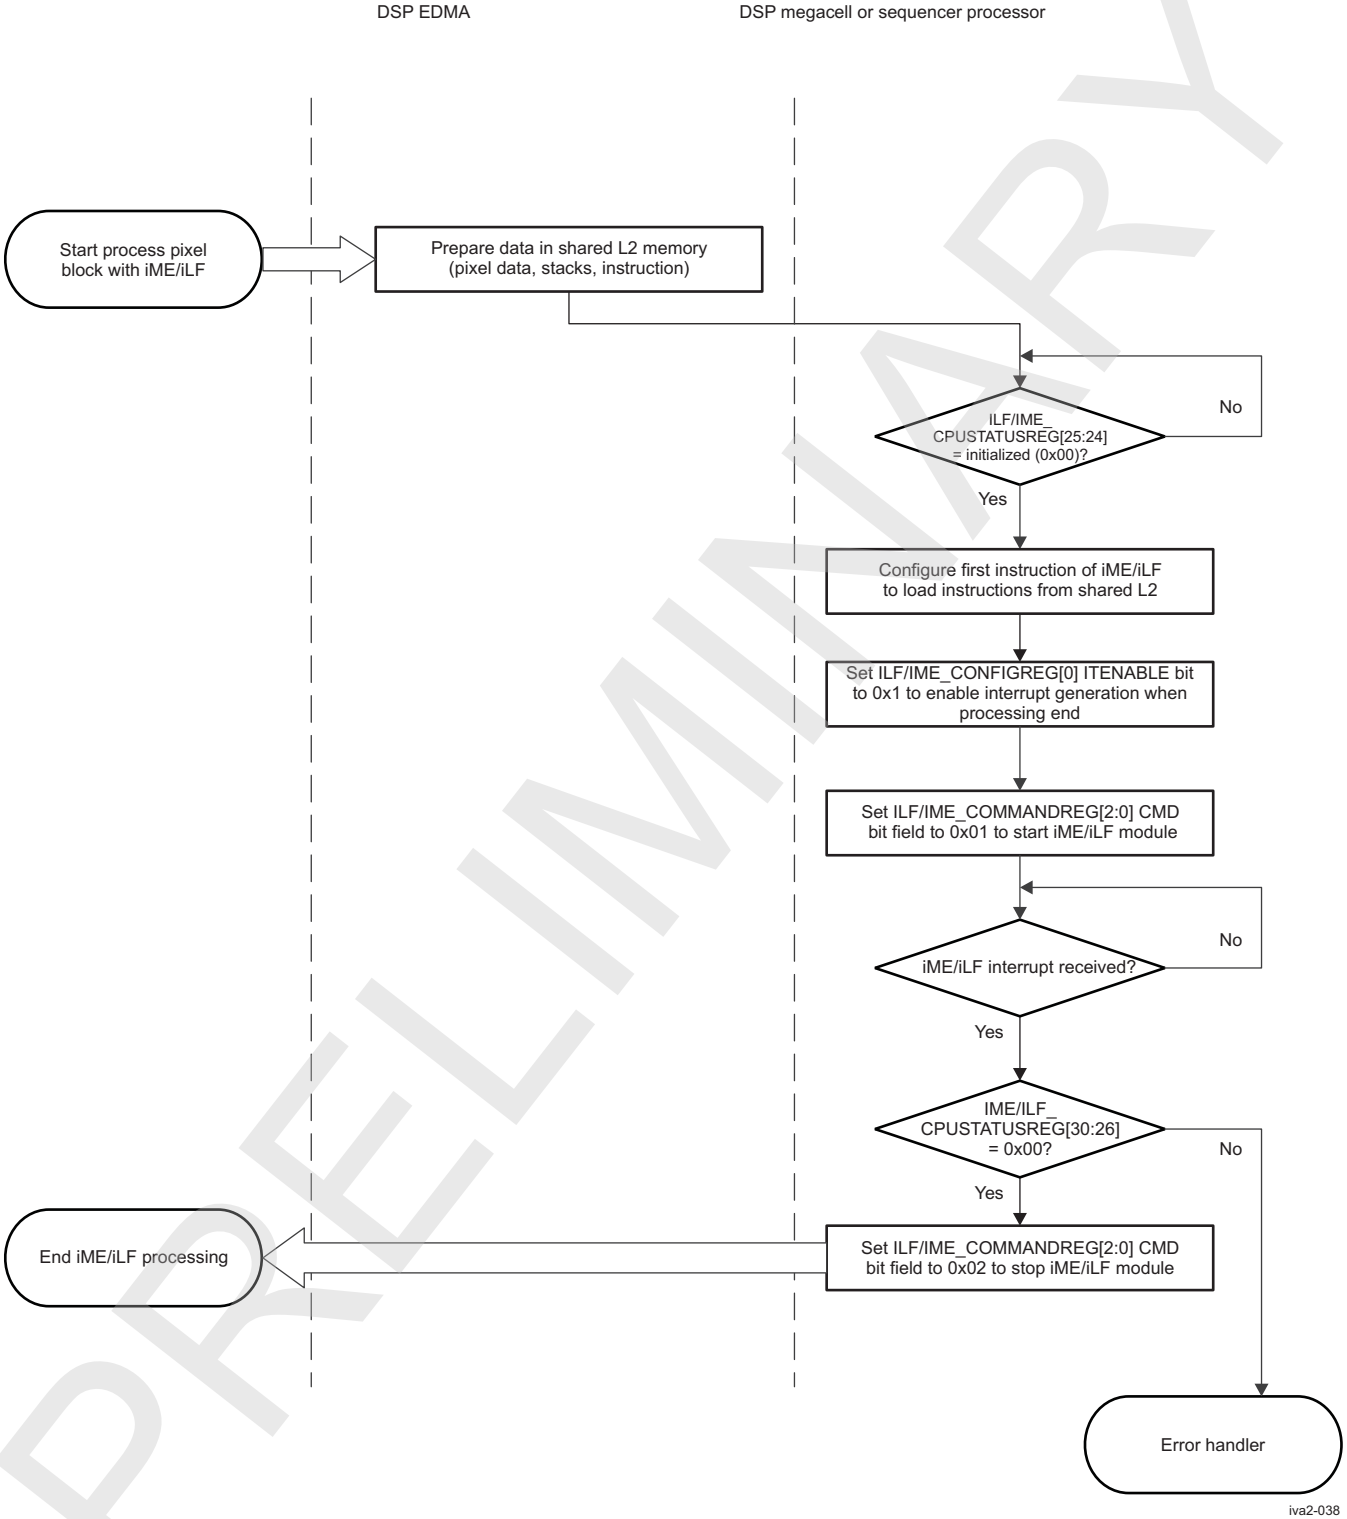
Step 8. Wait for the coprocessor interrupt (the DSP or sequencer is free to perform other tasks during coprocessor processing).

Steps 2, 3, and 4 can be performed with the help of the DSP EDMA, which can be configured by both the sequencer and the DSP megamodule.

Steps 5, 6, and 7 can be performed by both the sequencer and the DSP megamodule, but using the DSP megamodule for this task causes long DSP stalls because of high latency between the DSP megamodule and the iLF/iME module.

The DSP megamodule or the sequencer can prepare multiple sets of data in shared L2 memory (Steps 2, 3, and 4), then the sequencer can launch multiple processing with the coprocessor (Steps 6 and 7) until all prepared data sets in shared L2 memory are used. This way, the DSP and/or DSP EDMA is offloaded for a longer time. Figure 5-27 is a flowchart of a typical use of iLF/iME in video processing. In the flowchart, the four units (DSP, EDMA, sequencer, and coprocessor) work in parallel.

Figure 5-27. iME/iLF Typical Use Flowchart



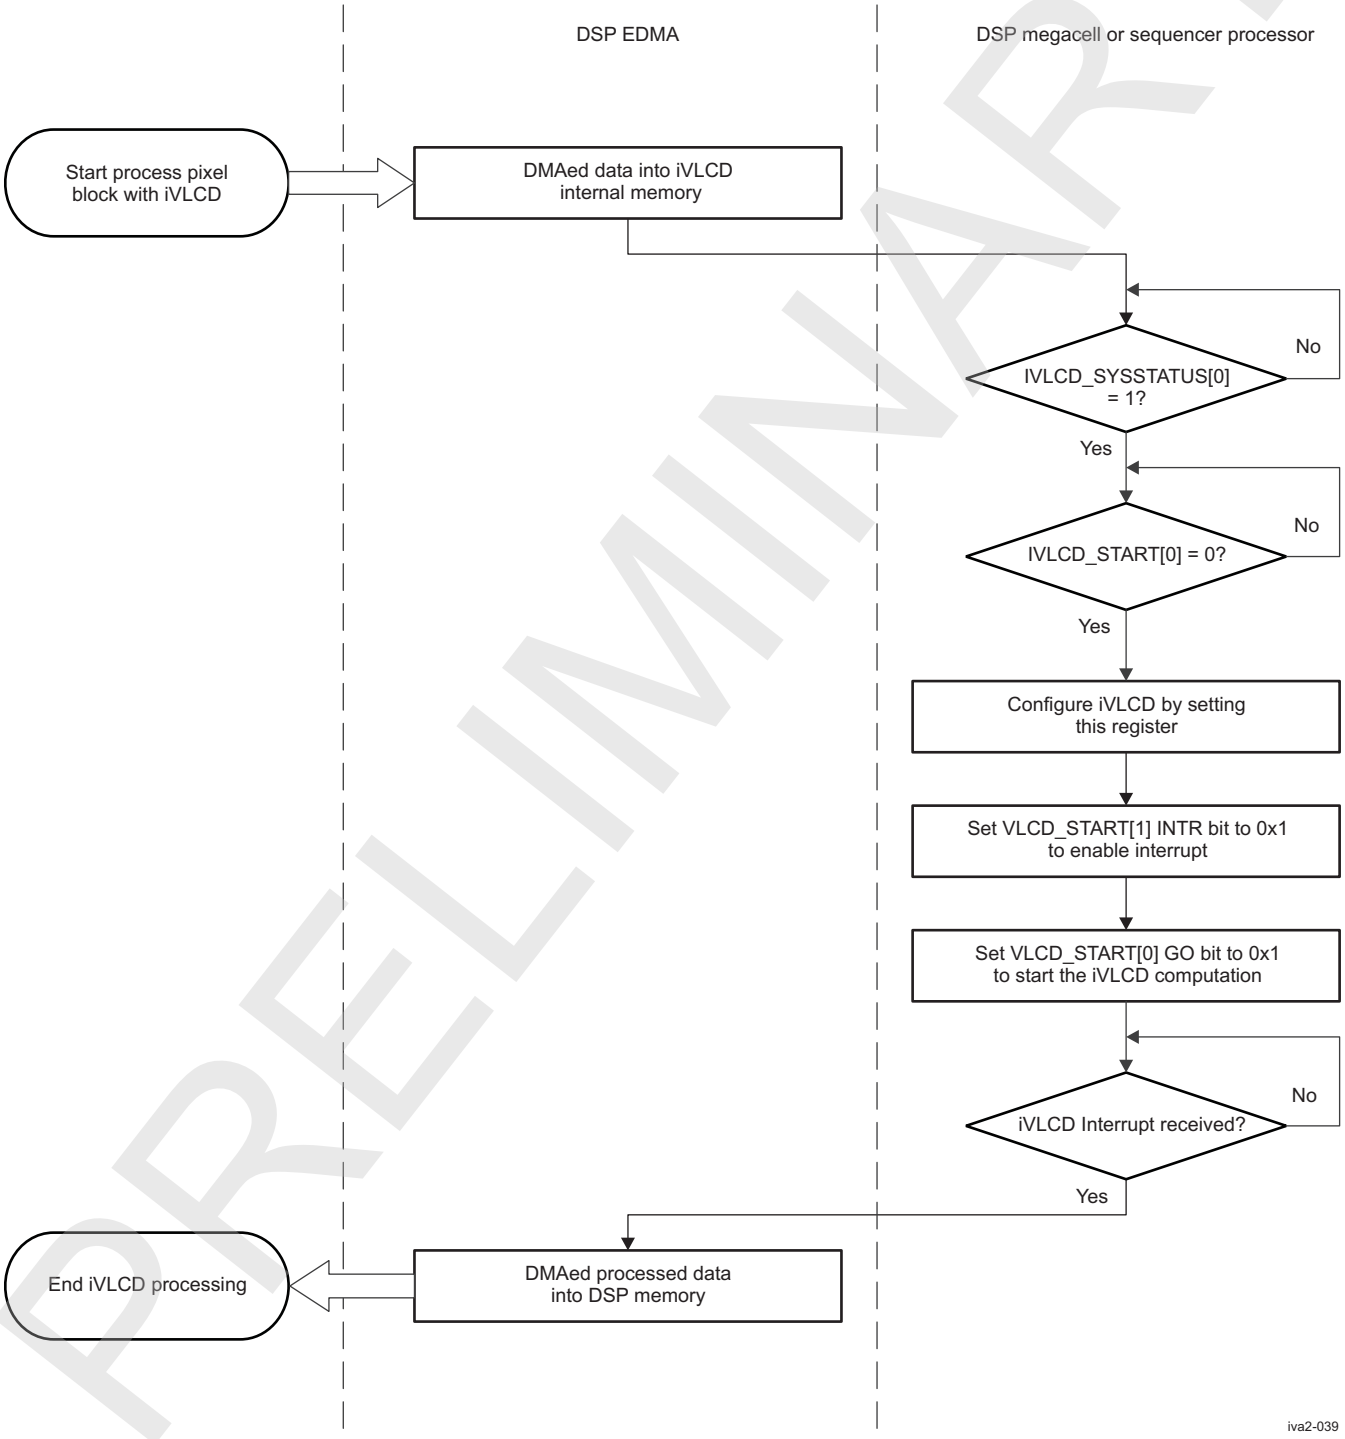
5.4.7 iVLCD Basic Programming Model

The iVLCD coprocessor is a parallel coprocessor where interrupt capabilities. It is partially autonomous, but unlike the iME/iLF, it does not retrieve information from shared L2 memory, so all data must be transferred to its memory through external means.

To accelerate transfer, the IVA EDMA has access to iVLCD local memories (see Section 5.3.2.2, *EDMA Access to Video Accelerator/Sequencer*). The EDMA can be programmed by the DSP megamodule or by the sequencer.

A typical use of iVLCD includes the 5 steps shown in Figure 5-28 .

Figure 5-28. iVLCD Typical Use Flowchart



5.4.7.1 Setting Up Registers for Q/IQ Operation

Before starting to encode or decode a bitstream, the Q/IQ registers and memory in the iVLCD module must be correctly initialized. Section 5.4.7.1.1, *Q/IQ Matrix Setup - Inverse Quantizer Matrix*, through Section 5.4.7.1.4, *Q/IQ Threshold*, describe the details.

5.4.7.1.1 Q/IQ Matrix Setup - Inverse Quantizer Matrix

Inverse_quantizer_matrix[0] = (1<<15)/DC_scaler

Inverse_quantizer_matrix[i = 1...63] = (1<<15)/quant_matrix(i = 1...63);

Quantization matrix values are either standard or embedded in the bitstream.

The inverse quantizer and quantizer matrices are selected by registers IVA.VLCD_QIQ_CONFIGj (j = 0 to 5).

5.4.7.1.2 Q/IQ Rounding

IVA.VLCD_MODE[15] MPEGRND bit = 1 implies that a rounding term (114) is added to the coefficients during quantization. IVA.VLCD_MODE[15] MPEGRND bit = 0 implies that quantization of the coefficients other than DC intra is performed without rounding.

DC intracoefficients are always quantized with a rounding term (1<<14).

5.4.7.1.3 Q/IQ Offset

IVA.VLCD_MPEG_DELTA_Q and IVA.VLCD_MPEG_DELTA_IQ are used for H.263 and MPEG4 type 0 inverse quantization.

The IVA.VLCD_MPEG_DELTA_IQ[8:0] MDELIQ field is set as follows:

if ((qp&0x1)==0) delta_q = qp-1;

else delta_q = qp;

where qp is the quantizer scale

The IVA.VLCD_MPEG_DELTA_Q[8:0] MDELQ field is set to 0.

For MPEG1/2, the IVA.VLCD_MPEG_DELTA_Q[8:0] MDELQ and IVA.VLCD_MPEG_DELTA_IQ[8:0] MDELIQ fields are set to 0.

5.4.7.1.4 Q/IQ Threshold

The IVA.VLCD_MPEG_THRED[11:0] MTHRED field is the quantization threshold for intra AC coefficients and intercoefficients.

There is no register setting for inverse quantization saturation. The inverse quantization function internally saturates intra AC coefficients and intercoefficients to between -2048 and 2047.

5.4.7.2 Setting Up Registers for VLC Operation

Before starting to encode a bitstream, the iVLCD must be initialized by initializing the coprocessor registers and setting up the VLC look-up tables. Some of those register initial values remain unchanged during a frame-encoding process, and others must be updated on a frame basis.

First, the VLC look-up tables must be loaded into the iVLCD table memory.

The VLC module operates on an N macroblocks basis. This means that when VLC is triggered, exactly N macroblocks of 64 elements are encoded. N must be specified to the encoder by setting the corresponding bits in the iVLCD control registers.

Programming the VLC involves two steps:

- Initialization: Parameters that remain constant throughout the encoding process are written into registers.
- Processing: The iVLCD is run as many times as necessary to encode the data. The VLC module operates on an N macroblocks basis. This means that each time VLC is triggered, exactly N blocks of 64 elements are encoded. N must be specified to the encoder by setting the corresponding bits in the iVLCD control registers. Because N generally remains constant during encoding, it is set during initialization. During processing, some registers set during initialization can be modified by the application or are modified by the VLC between the times it is run.

To perform the correct encoding operation, the IVA.VLCD_MODE register must have bits set to the correct values. By setting the following bits, the iVLCD coprocessor enables great flexibility, letting the programmer choose the type of encoded data format and the number of macroblocks encoded at a time:

- IVA.VLCD_MODE[2:0] FUNC field: Determines the VLC encode function: Value, 000 for Q, 001 for IQ, 010 for VLC, 011 for VLD, 100 for Q + IQ, 101 for Q + VLC, 110 for Q + IQ + VLC, 111 for VLD + IQ
- IVA.VLCD_MODE[7] MPEGINTRA bit: Determines whether the blocks to be encoded are intra macroblocks for MPEG encoding. For JPEG, this bit must be set to 1.
- IVA.VLCD_MODE[11] JPEGSYNC bit: Determines whether to insert the code 00 in the bitstream after getting a byte-aligned code of FF. Setting this bit to 1 activates 00 insertion. This bit must be set to 1 for JPEG.
- IVA.VLCD_MODE[14:12] NUMBLKS field: Specify the number of blocks of 64 elements to be processed each time the VLC coprocessor is triggered. Each block element is a 16-bit word and a maximum of 6 blocks can be encoded at once.
- IVA.VLCD_MODE[10] MPEGTYPE bit: Holds the value for MPEG picture coding type
- IVA.VLCD_MODE[8] INTRAVLC bit inMODE register: Specifies intra VLD decoding for MPEG modes: 0, use INTRA DC VLC table; 1, switch to INTRA AC VLC table.
- IVA.VLCD_MODE[6:4] MODESEL field: Tell the iVLCD what type of image coding is used: Value 000 for JPEG, 001 for MPEG1, 010 for MPEG2, 011 for H.263, 100 for MPEG4, 101 for MPEG4 data partition, 110 for MPEG4 RVLC/D, and value 111 is reserved.
- IVA.VLCD_VLCDIN_ADDR input address register:
- IVA.VLCD_VLCDOUT_ADDR output address register: Because the bit size of a codeword can be other than 16 bits, the bitstream buffer pointer register alone is not sufficient to determine the precise location of the next codeword to be written in the bitstream. To get the complete location, the next register must be used.
- IVA.VLCD_BITS_BPTR bits pointer register: Must contain a 4-bit value between 0 and 15 that is the bit position in the starting word of the bitstream. Because the VLC fills a codeword from the MSB to the LSB, this register is generally set to 15 at the beginning. After each run, the VLC updates the register by writing the bit position of the next codeword.
- IVA.VLCD_RING_START ring buffer start address register:
- IVA.VLCD_RING_END ring buffer end address register:
- IVA.VLCD_HUFFTAB_DCY Huffman DC Y table base address register: Holds the pointer to the Huffman table for luminance DC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_HUFFTAB_DCUV Huffman DC UV table base address register: Holds the pointer to the Huffman table for chrominance DC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_HUFFTAB_ACi (i = 0) Huffman AC0 table base address register: Holds the pointer to the Huffman table for luminance AC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_HUFFTAB_ACi (i = 1) Huffman AC1 table base address register: Holds the pointer to the Huffman table for chrominance AC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_LUMA_VECTOR LUMA bit-vector register: States which blocks must be treated as luminance blocks. This information is necessary because the Huffman table differs from luminance to chrominance data. For a complete description of this register, see Section 5.5, *IVA2.2 Subsystem Register Manual*.
- IVA.VLCD_MPEG_CBP MPEG coded block pattern register: Specifies which 8x8 blocks of each

macroblock must be coded. The Q/IQ module generates the CBP value after quantizing each macroblock.

NOTE: If VLC is performed separately from Q, the application must ensure that the CBP value corresponding to the macroblock is written to the VLCD_MPEG_CBP register before triggering the VLC. In JPEG mode, this register is ignored and every block is coded. (If iVLCD is configured to perform Q + VLC, this register contains the correct CBP value and is used for VLC.)

5.4.7.3 Setting Up Registers for VLD Operation

Before starting to decode a bitstream, the iVLCD must be initialized correctly by initializing the iVLCD control registers and setting up the UVLD symbol and control tables. Some initial register values remain unchanged during a frame decoding process and others must be updated on a frame basis.

First, the UVLD symbol and control tables must be loaded into the iVLCD Huffman table memory.

The iVLCD coprocessor operates on an N macroblocks basis. This means that when the iVLCD is triggered, exactly N blocks of 64 elements are decoded. N must be specified to the decoder by setting the corresponding bits in the iVLCD control registers.

Programming the VLD involves two steps:

- Initialization: Parameters that remain constant throughout the decoding process are written into registers.
- Processing: The iVLCD is run as many times as necessary to decode the data. The VLD module operates on an N macroblocks basis. This means that each time the iVLCD is triggered, exactly N blocks of 64 elements are decoded. N must be specified to the decoder by setting the corresponding bits in the iVLCD control registers. Because N generally remains constant during decoding, it is set during initialization. During processing, some registers set during initialization can be modified by the programmer or are modified by the VLD between the times it is run.

To perform the correct decoding operation, the IVA.VLCD_MODE register must have bits set to the correct values. By setting the following bits, the iVLCD coprocessor enables great flexibility, letting the programmer choose the type of decoded data format and the number of macroblocks decoded at a time:

- IVA.VLCD_MODE[2:0] FUNC field: Determines the VLC encode function: Value, 000 for Q, 001 for IQ, 010 for VLC, 011 for VLD, 100 for Q + IQ, 101 for Q + VLC, 110 for Q + IQ + VLC, 111 for VLD + IQ
- IVA.VLCD_MODE[7] MPEGINTRA bit: Determines whether the blocks to be decoded are intra macroblocks for MPEG decoding. For JPEG, this bit must be set to 1.
- IVA.VLCD_MODE[11] JPEGSYNC bit: Determines whether to ignore the code 00 in the bitstream after getting a byte-aligned code of FF. Setting this bit to 1 activates ignoring of 00. This bit must be set to 1 for JPEG.
- IVA.VLCD_MODE[14:12] NUMBLKS field: Specify the number of blocks of 64 elements to be processed each time the iVLCD coprocessor is triggered. Each block element is a 16-bit word and a maximum of 6 macroblocks can be decoded at once.
- IVA.VLCD_MODE[10] MPEGTYPE bit: Holds the value for Mpeg picture coding type
- IVA.VLCD_MODE[8] INTRAVLC bit: Specifies intra VLD decoding for MPEG modes
- IVA.VLCD_MODE[6:4] MODESEL field: Tell the iVLCD what type of image coding is used: Value 000 for JPEG, 001 for MPEG1, 010 for MPEG4, 011 for H.263, 100 for MPEG4, 101 for MPEG4 data partition, 110 for MPEG4 RVLC/D, and value 111 is reserved.
- IVA.VLCD_VLCDOUT_ADDR output address register: See , *Input and Output Data*.
- IVA.VLCD_VLCDIN_ADDR input address register: See , *Input and Output Data*. iVLCD updates this register each time it reads a codeword from the bitstream buffer. Because the bit size of a codeword can be other than 16 bits, the bitstream buffer pointer register alone is not sufficient to determine the precise location of the next codeword to be read from the bitstream. To get the complete location, the next register must be used.
- IVA.VLCD_BITS_BPTR bits pointer register: Must contain a 4-bit value between 0 and 15 that is the bit position in the starting word of the bitstream. Because the iVLCD reads a codeword from the MSB to the LSB, this register is generally set to 15 at the beginning. After each run, the iVLCD updates the

register by writing the bit position of the next codeword.

- IVA.VLCD_RING_START ring buffer start address register: See , *Input and Output Data*.
- IVA.VLCD_RING_END ring buffer end address register: See , *Input and Output Data*. The CTLTAB_DCY Y control look-up table base address register holds the pointer to the UVLD control table for luminance DC coefficients. The address is relative to the base address of the iVLCD Huffman table memory buffer and must be 32-bit-aligned.
- IVA.VLCD_CTLTAB_DCUV control look-up table base address register: Holds the pointer to the UVLD control table for chrominance UV DC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_CTLTAB_ACi (i = 0) control look-up table base address register: Holds the pointer to the UVLD control table for INTER AC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_CTLTAB_ACi (i = 1) control look-up table base address register: Holds the pointer to the UVLD control table for INTRA AC coefficients. The address is relative to the base address of the iVLCD Huffman table memory and must be 32-bit-aligned.
- IVA.VLCD_OFFSET_DCY symbol look-up table address offset register holds the offset value used to address the symbol table DC Y table. The purpose of this offset is to avoid negative numbers being used in the control table.
- IVA.VLCD_OFFSET_DCUV symbol look-up table address offset register: Holds the offset value used to address the symbol table DC UV table. The purpose of this offset is to avoid negative numbers being used in the control table.
- IVA.VLCD_OFFSET_ACi (i = 0) symbol look-up table address offset register: Holds the offset value used to address the INTER AC symbol table. The purpose of this offset is to avoid negative numbers being used in the control table.
- IVA.VLCD_OFFSET_ACi (i = 1) symbol look-up table address offset register: Holds the offset value used to address the INTRA AC symbol table. The purpose of this offset is to avoid negative numbers being used in the control table.
- IVA.VLCD_SYMTAB_DCY symbol look-up table base address register: Holds the address pointer to the starting word of the UVLD symbol table DC Y. This address is relative to the base address of the iVLCD coefficient buffer and must be 32-bit-aligned.
- IVA.VLCD_SYMTAB_ACi (i = 0) symbol look-up table base address register: Holds the address pointer to the starting word of the UVLD INTER AC symbol table. This address is relative to the base address of the iVLCD coefficient buffer and must be 32-bit-aligned.
- IVA.VLCD_SYMTAB_ACi (i = 1) symbol look-up table base address register: Holds the address pointer to the starting word of the UVLD INTRA AC symbol table AC 1. This address is relative to the base address of the iVLCD coefficient buffer and must be 32-bit-aligned
- IVA.VLCD_VLD_NRBIT_DC number of bits register: Specifies the number of bits to test for the DC term as input to UVLD. It equals the maximum length of a Huffman codeword. Bits 0-4 are associated with the UV terms and bits 8-12 with the Y terms.
- IVA.VLCD_VLD_NRBIT_AC number of bits register: Specifies the number of bits to test for the AC term as input to UVLD. It equals the maximum length of a Huffman codeword. Bits 0-4 are associated with the AC-1 terms and bits 8-12 with the AC-0 terms. VLD_CTL - iVLCD VLD control register controls:
  - Bits 4, 5, 6, and 7 specify whether UVLD tables for AC1, AC0, DCUV, DCY, respectively, are leading codeword bit 1 or leading codeword 0. For the first case, the bits must be set to 1, for the second case, the bits must be set to 0.
  - Bits 0, 1, 2, and 3 indicate the number of bits to represent the symbol in each entry of the UVLD symbol tables. Bit 0 is for AC1, bit 1 is for AC0, bit 2 is for DC UV, and bit 3 is for DC Y. If the bit is set to 0, the 11-bit symbol is used; otherwise, the 12-bit symbol is used.
- IVA.VLCD_LUMA_VECTOR bit-vector register: States which blocks are treated as luminance blocks. This information is necessary because the Huffman table differs from luminance to chrominance data. For a complete description of this register, see Section 5.5, *IVA2.2 Subsystem Register Manual*.
- IVA.VLCD_MPEG_CBP coded block pattern register: MPEG mode; must be updated after each macroblock processing. It specifies which 8x8 blocks of each macroblock must be decoded. For each macroblock there is a corresponding CBP value, which is stored along the bitstream in a header section. In JPEG mode, this register is ignored and every block is decoded.

When using the UVLD tables corresponding to the MPEG-1, MPEG-2, MPEG-4, and H.263 standards, see Table 5-19 for a list of register settings.

Table 5-19. iVLCD List of Register Values for Standard Algorithms

VLCD Register	MPEG1/2	MPEG4/H.263	JPEG
VLD_NRBIT_DC, bits 12-8: NrBits DC Y	7	7	9
VLD_NRBIT_DC, bits 4-0: NrBits DC UV	8	8	11
VLD_NRBIT_AC, bits 12-8: NrBits AC 0	16	12	16
VLD_NRBIT_AC, bits 4-0: NrBits AC 1	16	12	16
VLD_CTL, bit 7: One leading DC Y	1	0	1
VLD_CTL, bit 6: One leading DC UV	1	0	1
VLD_CTL, bit 5: One leading AC 0	0	0	1
VLD_CTL, bit 4: One leading AC 1	0	0	1
VLD_CTL, bit 3: Symbol size 11 DC Y	11	11	11
VLD_CTL, bit 2: Symbol size 11 DC UV	11	11	11
VLD_CTL, bit 1: Symbol size 11 AC 0 (INTER AC)	11	12	11
VLD_CTL, bit 0: Symbol size 11 AC 1 (INTER AC)	11	12	11
OFFSET_DCY, bits 10-0: control table offset DC Y	0	0	0
OFFSET_DCUV, bits 10-0: control table offset DC UV	0	0	0
OFFSET_AC0, bits 10-0: control table offset AC 0	0	-40	0
OFFSET_AC1, bits 10-0: control table offset AC 1	0	-40	0

5.4.7.4 Calculating the Number of Bits Processed During a VLD Run

To get the number of bits processed by the iVLCD during a VLD run, do the following:

1. Before VLD processing:
   (a) bits1 = VLCD_BITS_BPTR[3:0] BPTR value before VLD start
   (b) words1 = VLCD_VLCDIN_ADDR[12:0] ADDR value before VLD start
2. Start VLD processing:
3. After end of VLD processing
   (a) bits2: VLCD_BITS_BPTR[3:0] BPTR value after VLD start
   (b) words2: VLCD_VLCDIN_ADDR[12:0] ADDR value after VLD start
4. Number of bits processed. = (words2-wors1) * 16 - bits1 + bits2

5.4.7.5 Setting Up Registers for CAVLC Operation

Before starting to encode a bitstream, the iVLCD must be initialized correctly by initializing coprocessor registers and setting up the VLC look-up tables. Some initial register values remain unchanged during a frame encoding process and others must be updated on a frame basis.

First, the CAVLC look-up tables must be loaded into the iVLCD table memory.

Programming the CAVLC involves two steps:

- Initialization: Parameters that remain constant during the encoding process are written into registers.
- Processing: The iVLCD is run as many times as necessary to encode the data. During processing, some registers set during initialization can be modified by the application or are modified by the CAVLC between the times it is run.

Static registers need initialization only the first time:

- IVA.CAVLC_RBTOP: Set the buffer top pointer in Ibuf1/Ibuf0.
- IVA.CAVLC_RBEND: Set the buffer end pointer in Ibuf1/Ibuf0.
- IVA.CAVLC_BUFPTR: Set the pointer inside Ibuf1 from which the bitstream is written. The first time, IVA.CAVLC_BUFPTR is set to the IVA.CAVLC_RBTOP value (at the top of the Ibuf1 buffer).
- IVA.CAVLC_BITPTR: This register resets the first call of the CAVLC function. Set the number of MSB bits to be included in the valid bitstream in the stream word register.

- IVA.CAVLC_STRMWDU: This register resets the first call of the CAVLC function. This includes the upper half of the 32-bit stream word register. The value is less than 32 bits and specifies how many remaining bits are not written in the bitstream after iVLCD completion.
- IVA.CAVLC_STRMWDL: This register resets the first call of the CAVLC function. This includes the lower half of the 32-bit stream word register. The value is less than 32 bits and specifies how many remaining bits are not written in the bitstream after iVLCD completion.

  Because the encoded bitstream does not always finish as a complete 32-bit word at the end of 1-MB encoding, IVA.CAVLC_STRMWDU contains the upper short of the 32-bit word, IVA.CAVLC_STRMWDL contains the lower short, and CAVLC_BITPTR indicates how many bits are valid, starting from the MSB of IVA.CAVLC_STRMWDU.
- IVA.CAVLC_IBUFSEL: This register specifies input port, output port, and swapping configuration. If the CAVLC-generated bitstream is b0, b1... b15, b16... b31 ... (b0 is the first bit of the bitstream), and if the stream byte swap bit in IBUF_SEL is 0, the first 32 bits of the bitstream are stored in a 32-bit memory word as:

mem[31:24]	mem[23:16]	mem[15:8]	mem[7:0]
|b16b23	|b24,..,b31	|b0,,b7	|b8,..,b15|

If the stream byte swap bit is 1,

mem[31:24]	mem[23:16]	mem[15:8]	mem[7:0]
|b24...b31	|b16,..,b23	|b8, ..,b15	|b0,...,b7|

Initialize these registers each time the CALVC function is run:

- IVA.CAVLC_GO_REG: Setting this bit starts the CAVLC module. It is the same as a Start_sequence.
- IVA.CAVLC_MBTYPE: This register contains the MB type and the coded block pattern. The codec block pattern field has 6 bits. The cbp configuration is the same as that of the H.264 standard.
- IVA.CAVLC_HDPTR: Set a pointer on Hmem memory to read the MB header symbol and its length.
- IVA.CAVLC_HDCOUNT: This register contains the number of MB header pairs. The range of this value is 0 to 1023.
- IVA.CAVLC_NAPTR: Set a pointer on Hmem memory from which nA parameters are stored.
- IVA.CAVLC_NBPTR: Set a pointer on Hmem memory from which nB parameters are stored.
- IVA.CAVLC_COEFFPTR: Set a pointer on Ibuf0 memory to read residual data.

The following registers do not need to be initialized; they contain only information about the encoded bitstream:

- IVA.CAVLC_NUMTTL: This register specifies the total number of bits generated. This value considers remaining bits not yet written in the bitstream.
- IVA.CAVLC_NUMHD: This register specifies how many bits are generated from the MB header.
- IVA.CAVLC_NUMRESI: This register specifies how many bits are generated from residual data.

5.4.8 Interrupt Management

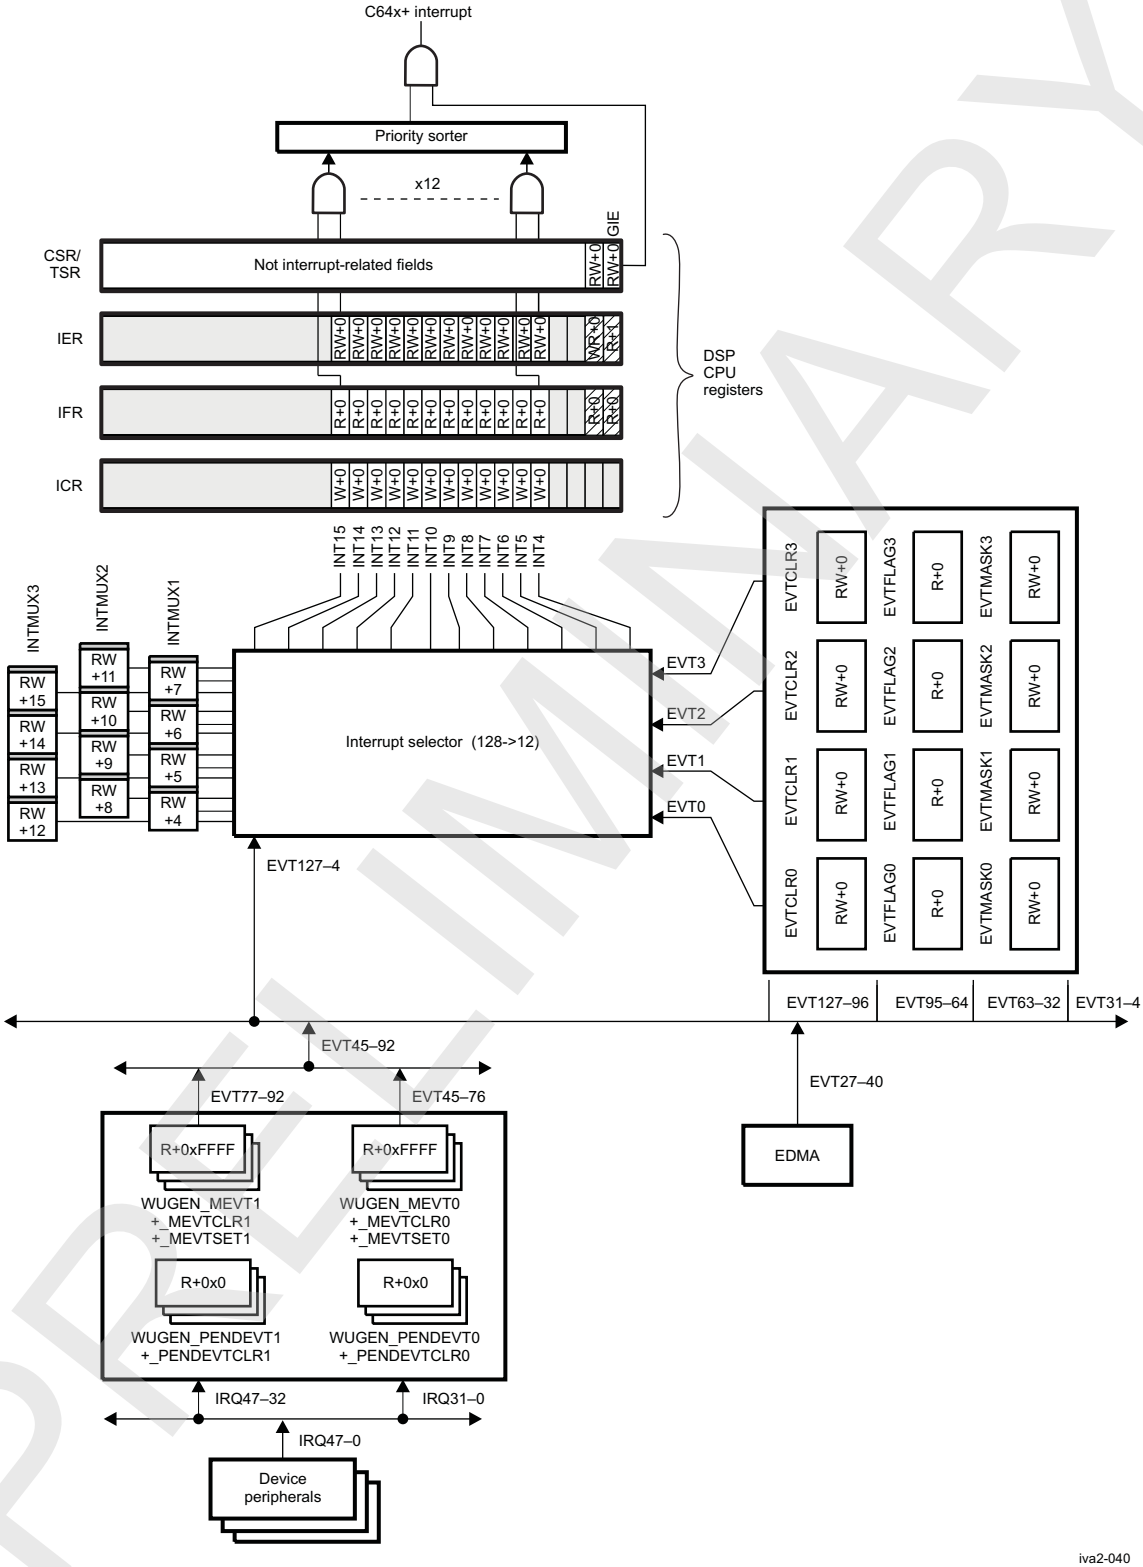
5.4.8.1 Interrupt Flow in IVA2.2 Subsystem

The DSP megamodule interrupt controller (IC) detects, combines, and routes up to 128 system events (internal and external) to the 12 DSP CPU interrupt lines. For more information about interrupt mapping of the IVA2.2 subsystem (internal and external interrupts), see Table 5-3.

In addition to performing handshaking for chip-level wake-up sequencing for waking from static power-down, the DSP megamodule WUGEN module internally routes the interrupt request to the IC module. This occurs because the WUGEN module is the only DSP megamodule module in the CORE power domain to enable the powered-off DSP subsystem to be awakened after the DSP receives an interrupt from any device peripherals.

Figure 5-29 shows the IVA2.2 subsystem interrupt flow with the main WUGEN and IC registers used for event generation.

Figure 5-29. IVA2.2 Interrupt Flow



NOTE: The CSR/TCR, IER, IFR, and ICR registers belong to the DSP CPU block (C64x+). For more information, see the C64x+ documentation (Section 5.3.1.8).

5.4.8.2 Event Combined Programming Sequence

In addition to generating a combined interrupt based on programmable event combinations, the event combiner provides a masked view of the event flag registers. By reading the masked event flag (IVA_IC.MEVTFLAGi where i = {0 to 3}) registers, the DSP CPU sees only the event flags pertaining to the corresponding combined event (EVTx with x = {0, 1, 2, 3}).

When servicing a combined interrupt, perform the following steps:

1. Read the IVA_IC.MEVTFLAGi register corresponding to the combined event EVTx (where i = {0 to 3}).
2. Check the pending events.
3. Write the value of the IVA_IC.MEVTFLAGi register into the IVA_IC.EVTCLRx register (where i = {0 to 3}).
4. Service the received interrupts.
5. Repeat steps 1 through 4 until IVA_IC.MEVTFLAGi = 0x0 (where i = {0 to 3}).

This clears only those events combined on EVTx. Any events masked in the IVA_IC.EVTMASKi register (where i = {0 to 3}) do not need to be cleared if set in the IVA_IC.EVTFLAGi register (where i = {0 to 3}) (they can generate an exception or are used as event outputs).

Before returning, the DSP CPU should repeat steps 1 through 4 until no pending events are found. This ensures that any events received during the ISR are captured. If an event EVTx is received at the same time that its flag is being cleared in the IVA_IC.EVTCLRi register (where i = {0 to 3}), it does not clear. Repeating steps 1 through 4 ensures that no events are missed.

5.4.8.3 Event <-> Interrupt Mapping Programming Sequence

The INTC allows programming independently which of the 128 inputs events is mapped to each DSP CPU interrupt by writing the event number in the bit field corresponding to the CPU interrupt in the IC.INTMUXj registers (where j = {1 to 3}).

Example:

```
/* ---------------------------------------------------- */
/*evtTable has the 12 evt <-> CPU interrupt mapping */
/* ---------------------------------------------------- */
evtTable[0] = 55; // Mailbox event highest priority
evtTable[1] = 61; // McBSP1TX event
[...]
evtTable[11] = 29; // EDMA3 gbl completion event lowest priority
for(I=0; i<12; I++) {// for each CPU maskeable interrupt
INTMUX(I >> 2 + 1) |= (evtTable[i] & 0x7F) << ((I & 0x3) << 3);
}
```

5.4.8.4 Interrupt Exception Programming Sequence

The INTC can generate a system event (INTERR) that is internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is dropped (that is, when a DSP CPU interrupt is received while the interrupt flag is already set in the DSP CPU).

This can inform the user of possible problems in the software code, such as whether interrupts were disabled for an extended period of time, or whether pipelined (noninterruptible) code sections were too long.

NOTE: Because the interrupt drop detection logic is in the CPU, only interrupts sourced from a single system event can be detected. The dropping of individual combined events is not possible, although dropping the output of an event combiner is possible. Only the first dropped interrupt detected is reported by the INTERR event.

The IVA_IC.INTXSTAT register holds the ID of the CPU interrupt and the system event number of the dropped event. By setting the IVA_IC.INTXCLR[0] CLEAR bit to 1, the software user resets the IVA_IC.INTXSTAT register to 0.

When servicing the interrupt exception, the CPU performs three steps:

1. Reads the IVA_IC.INTXSTAT register
2. Checks the error condition
3. Clears the error through the IVA_IC.INTXCLR register

The dropped events that generate the INTERR event (EVT96) can be qualified by a mask register. CPU interrupts that are to be ignored by the drop detection hardware can be masked in the IVA_IC.INTDMASK register.

5.4.8.5 Interrupt Controller Basic Programming Model for Power Down of IVA2.2 Subsystem

When going to a low-power state not involving IVA2.2 logic power off, there are no special software settings to perform. In particular, the noncombined interrupts can be used without any specific handling for that power transition. To run the procedure for a correct transition to power-down state not involving logic-off, the user must perform the following sequence:

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear associated bits in the WUGEN_MEVT0 and WUGEN_MEVT1 register to unmask wake-up interrupts.

NOTE: Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

The user must program the following procedure when transitioning to the (logic) power-off state (OFF state for device):

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts, and are unmasked in combined event registers (if combined events are used).
2. Clear correct bits in the WUGEN_MEVT0 and WUGEN_MEVT1 registers to unmask wake-up interrupts.
3. Save necessary context (all except interrupt-related registers).

NOTE: Steps 3 through 5 are automatic, but interruptible. If a wake-up interrupt occurs at this stage, the transition to power down is canceled and the next transition restarts from the beginning. Software tip: A software variable (semaphore) can be set in Step 3, modified in all calls of the wake-up interrupt ISR routine, and checked before executing the IDLE instruction in Step 5. For a complete description of the DSP CPU ISR register, see the C64x+ documentation (Section 5.3.1.8).

4. Save the interrupt configuration in:

   (a) IVA_IC.INTMUXj register (where j = {1 to 3})
   (b) IVA_IC.EVTMASKi register (optional, where i = {0 to 3})
   (c) IVA_IC.INTDMASK register (optional)
   (d) DSP CPU IER register. See the C64x+ documentation for IER register description (Section 5.3.1.8).
5. Execute the DSP IDLE instruction.

NOTE: Software must not unmask in the WUGEN module an event that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the IVA2.2 subsystem exits the power-down state but does not wake up.

5.4.8.6 Interrupt Controller Basic Programming Model for Power On of IVA2.2 Subsystem

Noncombined events can be lost after power on wakeup of the DSP megamodule module. To avoid this, one solution is to replay the DSP CPU interrupt after restoring the interrupt selector and event combiner context.

- Programming model at boot time

There is no specific software setting needed to use combined/noncombined events during normal operation. However, at boot time, the event can be captured in the event-combiner event flag and not propagated to DSP. For this purpose, the following sequence must be performed:

1. The IVA2.2 logic ensures that interrupts are only presented to DSP megamodule after:
   (a) The DSP megamodule module has its clock.
   (b) The DSP megamodule module is correctly reset.

NOTE: Steps a and b ensure that the DSP megamodule module cannot miss a dropped event.

2. From the time the pre-idle sequence is started to the time when the IVA2.2 context is fully restored and operational after wakeup, it is assumed that only external (from device peripherals) interrupts can occur. DSP megamodule internal interrupts can result only from an application software side-effect; the application is stopped when entering the pre-idle sequence and is restarted only after IVA2.2 context is fully restored and operational (with special attention to memory protection). EDMA interrupts are inactive at this stage, as the EDMA module is completely reset after power up, and a software action is required to make the EDMA interrupts active again.
3. All device peripheral interrupts are level and are kept asserted until the software acknowledges the interrupt by writing 1 to the interrupt status register (DSP CPU ISR) bit corresponding to the enabled asserted event(s). The device peripheral must keep an event flag to track missed interrupts. For a complete description of the DSP CPU ISR register, see the C64x+ documentation (Section 5.3.1.8).
4. There is no specific requirement to configure or restore interrupt mapping, except having the interrupts globally disabled during the sequence:
   (a) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 0 to disable all interrupts except the reset interrupt and NMI (nonmaskable interrupt). The GIE bit is the same physical bit in the TSR and CSR registers. For a complete description of these registers, see the C64x + documentation (Section 5.3.1.8).
   (b) Remap interrupts by configuring the IVA_IC.INTMUXj registers (where j = {1 to 3}).
   (c) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 1 to enable all DSP CPU interrupts.

The DSP CPU software recognizes which degree of power state the C64x reaches when executing the IDLE instruction, because the PRCM module is under C64x software control. Therefore, the DSP CPU software can correctly skip some unnecessary parts of the pre-idle routines.

- State after reset for DSP CPU and IVA2.2 IC registers:
  - The DSP CPU IER register value is 0x0.
  - The DSP CPU IFR register value is 0x0 because the interrupt selector default mapping is routing only emulation and unmapped events.
  - The IVA_IC.INTMUXj registers (where j = {1 to 3}): The default mapping is to route EVTx (with x = {0 to 3}) on INTy (with y = {4 .. 15}), that is, emulation and nonmapped events.
  - The IVA_IC.EVTMASKi registers (where i = {0 to 3}) value is 0x0 (all events are unmasked). These registers values are don't care values because of the default interrupt selector mapping (where iVA_IC.INTMUXj registers where j = {1 to 3}).
  - The IVA_IC.EVTFLAGi registers (where i = {0, 1, 2, 3}): These registers log the possible wake-up interrupt(s) (if more than one). At this stage, a new wake-up interrupt from device peripherals cannot be missed, because interrupts are level in the device, waiting for a software acknowledge (the user must clear the interrupt in the module to deassert the interrupt line).

For a complete description of the DSP CPU IER and IFR registers, see the C64x+ documentation (Section 5.3.1.8).

- State after reset for WUGEN registers: two cases depending on the reset type:
  - In case of cold power-on reset (the CORE power domain was in OFF state), the IVA_WUGEN.WUGEN_MEVT0 register value is 0xFFFFFFFF and the IVA_WUGEN.WUGEN_MEVT1 register value is 0xFFFF, meaning that all interrupts are masked.
  - In case of warm power-on reset (the CORE power domain was in ACTIVE state), the WUGEN_MEVT0 and WUGEN_MEVT1 registers value is the previous programmed one, enabling only wake-up interrupts.

- Programming model for a correct warm-reset:

The software user must replay the noncombined events required for wakeup (if any):

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
   (a) IVA_IC.INTMUXj register (where j = {1 to 3})
   (b) IVA_IC.EVTMASKi register (optional, where i = {0 to 3})
   (c) IVA_IC.INTDMASK register (optional)
3. Replay the noncombined event captured in IVA_IC.EVTFLAGi (where i = {0 to 3}):
   For each DSP CPU interrupt I = (4 to 15)
   {
   (a) Grab mapped event by setting the IVA_IC.INTMUXj INTSELi[6:0] field (where j = {1 to 3}).
   (b) Check if the event is combined (EVT0...3) or not combined (EVT4...127).
   (c) If combined, exit the loop and go to next loop iteration.
   (d) If noncombined:
      (i) Check whether the event is pending in the IVA_IC.EVTFLAGi EFy bit (where i = {0 to 3} and y = {0 to 127}).
      (ii) If not pending, exit the loop and go to the next loop iteration.
      (iii) If pending, set the associated IFi bit in the DSP CPU IFR register.
   }

NOTE: Software must ensure that an event is enabled only once in the DSP megamodule interrupt selector/combiner: If a noncombined event is mapped to an enabled DSP CPU interrupt, the associated combined event is masked in the associated IVA_IC.EVTMASKi (where i = {0 to 3}) register (and/or the combined event is not mapped to the DSP CPU interrupt). Reciprocally, if a combined event is mapped to a DSP CPU interrupt, all the unmasked events in the associated IVA_IC.EVTMASKi (with i = {0, 1 to 3}) register are not mapped as noncombined events to an enabled DSP CPU interrupt (through the DSP CPU IER register).

Software program example for Step 3:

```
/* ------------------------------------------------- */
/* Replays IFR bits associated to noncombined events */
/* Assumes interrupts globally disabled (GIE bit set to 0)*/
/* Assumes IVA_IC.INTMUXj() and IVA_IC.EVTFLAGi() are access macros to DSP megamodule IC
registers */
/* ------------------------------------------------- */
myIPR = IPR; // save IPR
for(I=0; i<12; I++) { // for each CPU maskable interrupt
myEvt = ( INTMUX( I >> 2 + 1) >> ( (I & 0x3) << 3 ) ) & 0x7F;
if(myEvt >= 4) { // noncombined event
if( (EVTFLAG(myEvt >> 5 ) >> (myEvt & 0x1F ) ) & 0x1 ) {
myIPR |= (1<<(I+4));
}
}
}
IPR=myIPR; // update IPR register
/* ------------------------------------------------- */
/* Interrupts can be globally re-enabled from that point*/
/* ------------------------------------------------- */
```

4. Restore the CPU interrupt configuration by setting the DSP CPU IER register accordingly.
5. Restore the IVA2.2 context (except saved return-PC).
6. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.

7. Branch to saved return-PC.

For a complete description of the DSP CPU TSR, CSR, IER, or IFR registers, see the C64x+ documentation (Section 5.3.1.8).

- Procedure for a correct cold reset

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
   (a) IVA_IC.INTMUXj register (where j = {1 to 3})
   (b) IVA_IC.EVTMASKi register (optional, with i = {0 to 3})
   (c) IVA_IC.INTDMASK register (optional)
3. It is unnecessary to replay events, because they are masked in WUGEN_MEVT0 and WUGEN_MEVT1 registers (default WUGEN module configuration). This can be done to simplify the boot sequence without discriminating between cold and warm reset.
4. Restore the CPU interrupt configuration by setting the DSP CPU IER REGISTER accordingly.
5. Restore the WUGEN module context. This can be forced even in warm reset to simplify the boot sequence without discriminating between cold and warm reset.

NOTE: If Steps 3 and 5 are performed systematically, the boot code can be shared between warm and cold reset boot without programming two distinct software boot codes.

6. Restore the rest of the IVA2.2 subsystem context (except saved return-PC).
7. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
8. Branch to saved return-PC.

5.4.8.7 Video and Sequencer Module interrupt Handling

5.4.8.7.1 Sequencer Interrupt

The sequencer uses a single FIQ interrupt. This single interrupt is driven by all the video accelerator interrupts, DSP EDMA interrupts, DSP megamodule soft interrupts, and error interrupts. Registers are available to manage these interrupts in the sequencer.

Before servicing an interrupt, the sequencer ISR must:

1. Identify the source event(s) for the interrupt line assertion
2. For each source event:
   (a) Clear the interrupt at the source (in the module interrupt clear register)
   (b) Clear the interrupt at the second-level (sequencer) interrupt controller
   (c) Service the interrupt event

5.4.8.7.2 DSP Megamodule Interrupt

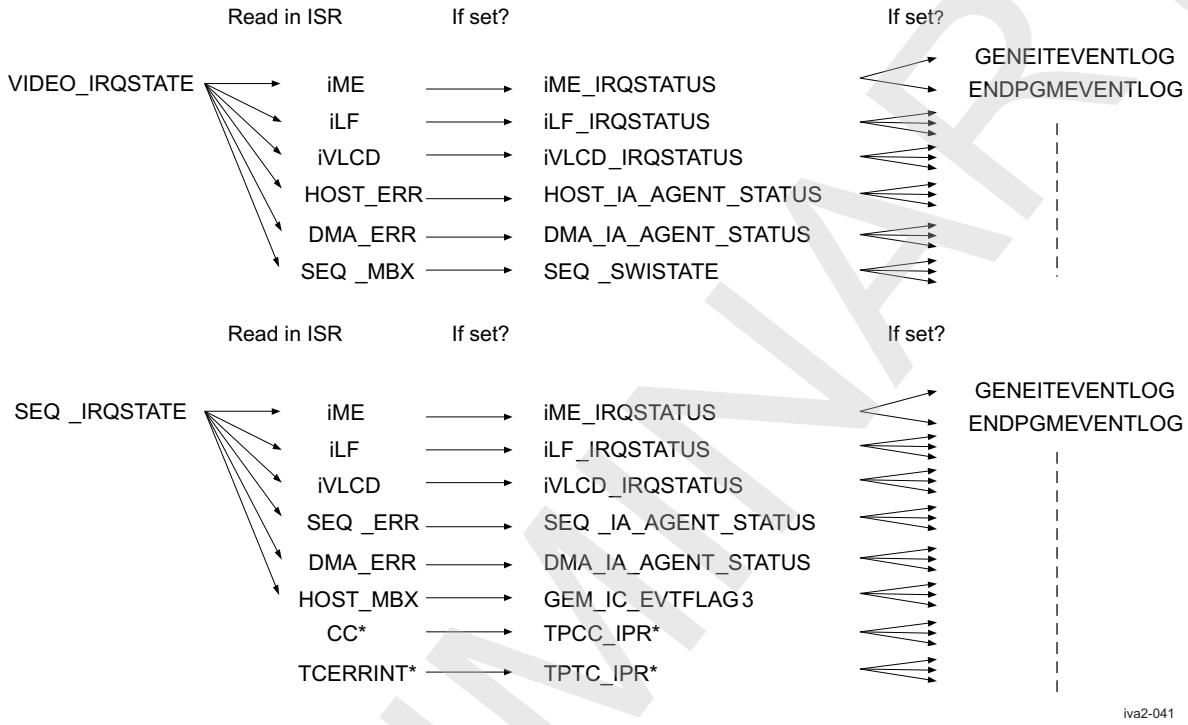
A single interrupt line is used per processor to gather all events that might require an interrupt of the DSP megacell. This interrupt line is shared by all the modules responsible for generating an interrupt request to the associated processor (iME, iLF, iVLCD, DSP megacell initiator error, DMA initiator error, and sequencer soft interrupt). In turn, each of these modules has a single interrupt request output that is shared by all events internal to the module.

Before servicing an interrupt, the processor (DSP megacell) ISR must:

1. Identify the source event(s) for the interrupt line assertion
2. For each source event:
   (a) Clear the interrupt at the source (in the module interrupt clear register)
   (b) Clear the interrupt at the second-level interrupt controller
   (c) Clear the interrupt at the DSP interrupt controller (if combined interrupt is used, see Section 5.4.8.2, *Event Combined Programming Sequence*, for details)
   (d) Service the interrupt event
3. Acknowledge the interrupt to the processor

Step 1 is done hierarchically through reading the IVA.VIDEOSYSC_IRQSTATE register and, depending on which bit is set, through reading of the IVA.module>_IRQSTATUS registers (or equivalent) (see Figure 5-30). Step 2 is done hierarchically, as well, but in the reverse order, using IVA.module>_IRQCLEAR (or equivalent) first and then IVA.VIDEOSYSC_IRQCLR (IVA.SEQ_IRQCLR, respectively).

Figure 5-30. Process of Identifying Source Event of an Interrupt



5.4.9 Memory Management

5.4.9.1 External Memory

5.4.9.1.1 Cacheability

The L1P, L1D, and L2 cache sizes are all 0K byte after reset.

- The user enables the L2 cache by writing 0x2 (maximum cache is 64K bytes) to the IVA_XMC.L2CFG register.
- However, this is not sufficient, because the region external to the IVA2.2 is configured as a noncached area after reset. The user must configure the external area to be cached by setting the IVA_XMC.MARi[0] PC bit to 1, i referring to the index of the related 16-MB page (starting from i = 16 for the first external page at address 0x1000 0000).

The MAR settings only control the L2 and L1D cache's response to CPU data and program fetches. L1P caches the memory range regardless of the values of the MAR bits.

5.4.9.1.2 Virtual Addressing

The device embeds two instances of MMU: one instance is camera MMU (also named MMU1) dedicated to the camera subsystem; the other instance is IVA2.2 MMU (also named MMU2) used by the IVA2.2 subsystem. For more information about MMU2 software settings at IVA2.2 boot, see Section 5.4.1.2, *Example of IVA2.2 Boot*.

For a complete programming guide of IVA2.2 MMU, see Chapter 15, *Memory Management Units*.

5.4.9.2 Internal Memory

5.4.9.2.1 Memory Protection

The DSP megacell memory protection divides the memory map into pages and defines a per-page permission structure. This permission structure is in the MPPA registers: IVA_XMC.L1PMPPAk, IVA_XMC.L1DMPPAk, IVA_XMC.L2MPPAj for L1P, L1D, L2 memory protection, and TPCC_MPPAG, TPCC_MPPAj for EDMA memory protection. Figure 5-31, Figure 5-32, and Figure 5-33 show which register corresponds to each page permission structure.

Figure 5-31. L1P Memory Protection Registers

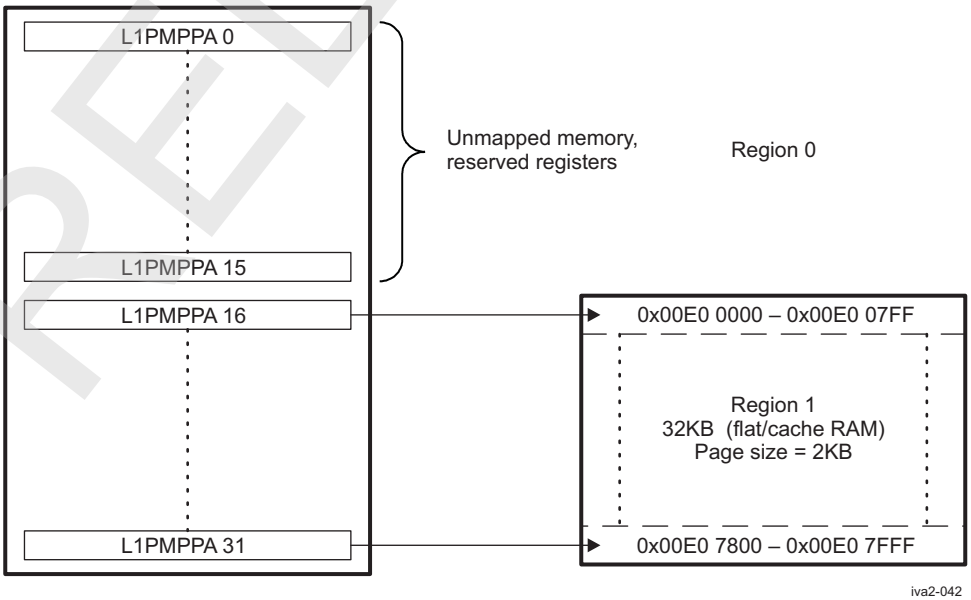


Figure 5-32. L1D Memory Protection Registers

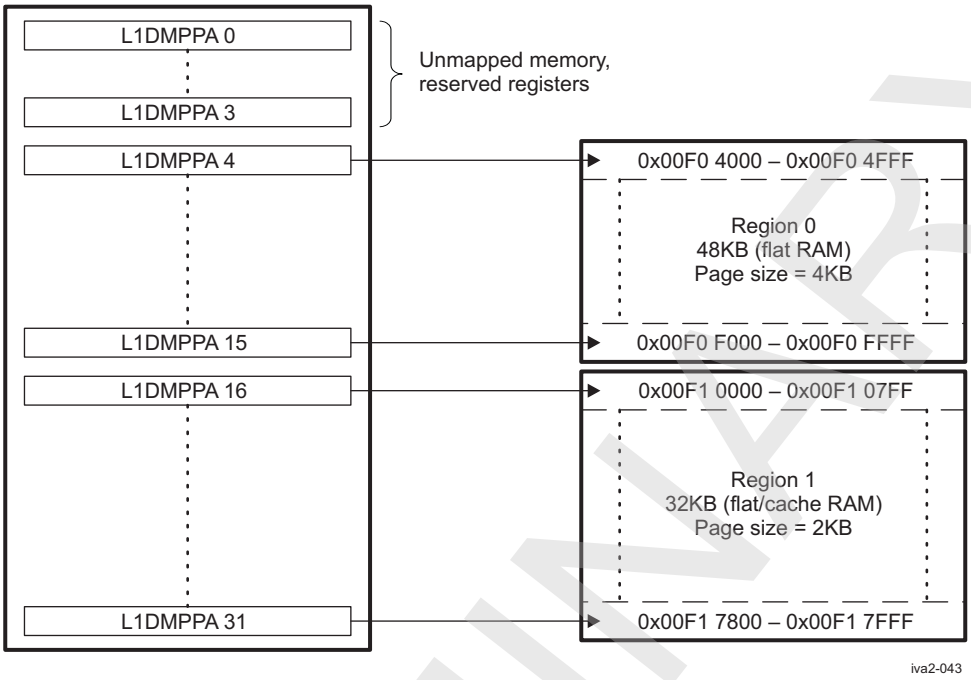

Figure 5-33. L2 Memory Protection Registers

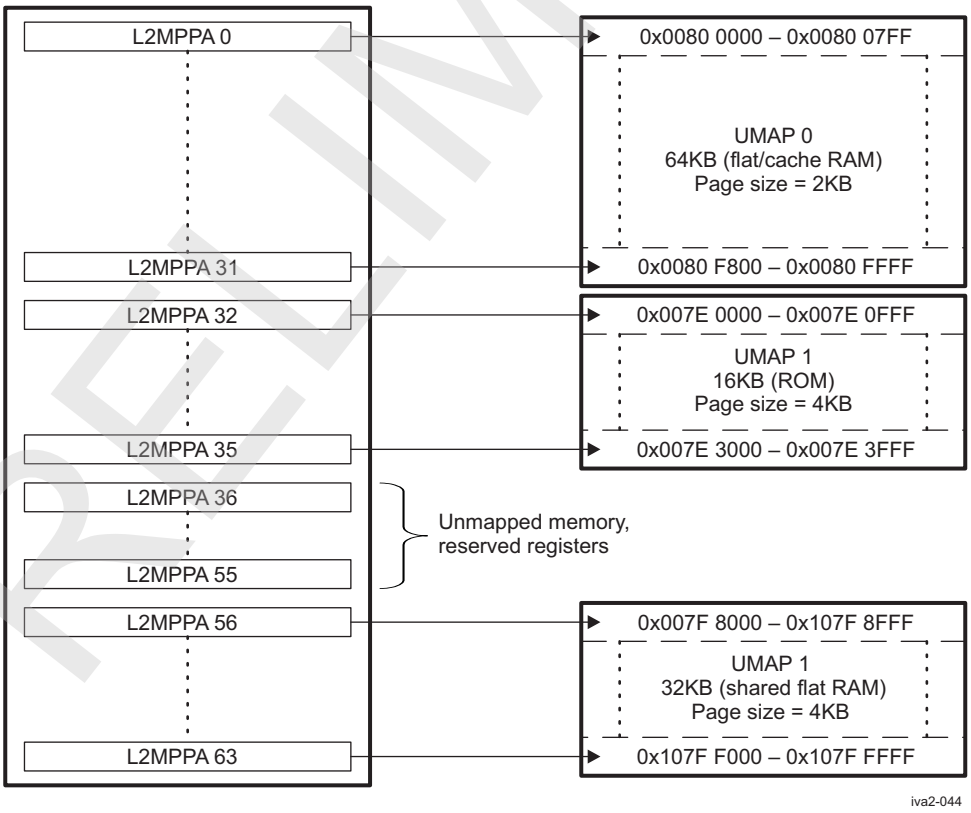

NOTE: When memory is used as cache, all its corresponding MPPA registers should be set to 0x0000.

Table 5-20 shows which register corresponds to each memory address for megacell internal memory.

Table 5-20. IVA2.2 Megamodule Memory Protection Page Registers

Register Number	L1PMPPAk, Address Range	L1DMPPAk, Address Range	L2MPPAj, Address Range
0	N/A[1]	N/A	0x0080 0000 - 0x0080 07FF
1	N/A	N/A	0x0080 0800 - 0x0080 0FFF
2	N/A	N/A	0x0080 1000 - 0x0080 17FF
3	N/A	N/A	0x0080 1800 - 0x0080 1FFF
4	N/A	0x00F0 4000 - 0x00F0 4FFF	0x0080 2000 - 0x0080 27FF
5	N/A	0x00F0 5000 - 0x00F0 5FFF	0x0080 2800 - 0x0080 2FFF

(1) N/A = nonmapped memory. All corresponding registers should be considered reserved.

Table 5-20. IVA2.2 Megamodule Memory Protection Page Registers (continued)

Register Number	L1PMPPAk, Address Range	L1DMPPAk, Address Range	L2MPPAj, Address Range
63	-	-	0x007F F000 - 0x007F FFFF

All these registers include three permission fields in a 16-bit permission entry in the memory protection page attribute MPPA register:

- Allowed ID field:

  Each requestor on the device has an N-bit code associated where it that identifies it for privilege purposes. This code, referred to as the VBUS PrivID, accompanies all memory accesses and DMAs/IDMAs on behalf of that requestor. That is, when a requestor triggers a DMA/IDMA transfer directly, either by writing to IDMA registers or by triggering the execution of a set of EDMA parameters, the corresponding DMA engine captures the PrivID of the requestor and provides that PrivID with the transfer.

  Each memory protection entry is associated with an 8-bit allowed-IDs field that indicates which requestors can access the given page. The memory protection hardware maps the PrivIDs of all possible requestors to bits in the allowed-IDs field in the memory protection entries. The allowed-IDs field discriminates among the various CPUs, non-CPU requestors, and the accesses of a given CPU to its own local memories:

  – AID0 through AID5 map small-numbered VBUS PrivIDs to allowed ID bits.
  – An additional allowed-ID bit, AIDX, captures accesses by higher-numbered PrivIDs.
  – The LOCAL bit treats CPU accesses to its local L1s and L2 specially. Only the L1 and L2 memory controllers implement the LOCAL bit.

  When set to 1, the AID bit grants access to the corresponding PrivID. When set to 0, the AID bit denies access to the corresponding requestor.

  PrivID assignments for bits AID0 through AIDX apply to:

  – CPU memory and IDMA memory: IVA_XMC.L1PMPPAk[15:9] for L1P memory, IVA_XMC.L1DMPPAk[15:9] for L1D memory, and IVA_XMC.L2MPPAj[15:9] for L2 memory
  – EDMA memory: TPCC_MPPAG[15:9] and TPCC_MPPAj[15:9] for EDMA block

  The AIDX bit maps to PrivIDs that do not have dedicated AID bits associated with them. This bit refers to external mastering peripherals, especially on devices with a large number of CPUs. If a given device must discriminate among external mastering peripherals, it can assign lower-numbered PrivIDs to these peripherals.

  For the EDMA module, the AIDX bit is the TPCC_MPPAj[9] and TPCC_MPPAj[9] EXT bits.

  The LOCAL bit governs DSP CPU accesses to its own local L1 and L2 memories. It is defined in IVA_XMC.L1PMPPAk[8] for L1P memory, in IVA_XMC.L1DMPPAk[8] for L1D memory, and in IVA_XMC.L2MPPAj[8] for L2 memory. It is not defined for EDMA.

  With respect to the allowed ID field, the DSP megamodule treats all remote CPU accesses to DSP megamodule memories identically to DMA accesses from that remote CPU. Therefore, DSP megamodule uses the PrivID to consult the corresponding AID bit when considering remote accesses.

  However, the DPS megamodule module never compares local accesses to L1 and L2 memory against the AID bits in the allowed ID field. Instead, it consults the LOCAL bit to determine whether the CPU can access its local memory.

  With this scheme, a software program can designate a page as direct CPU access only by setting the LOCAL bit to 1 and setting all other allowed IDs to 0. Conversely, a software program can designate a page as DMAs issued from this CPU only by setting its AID bit and clearing the LOCAL bit. Such a setting is limited, but it can be useful in a sensitive environment, or in the context of a device driver.

- Request-Type Based Permissions field:

  The DPS megamodule memory protection model defines three fundamental functional access types: read, write, and execute. Read and write refer to data accesses originating through the load/store units on the DSP CPU or through the DMA/IDMA engines. Execute refers to accesses associated with program fetch.

  The DSP megamodule memory protection model allows control of read, write, and execute permissions independently for both user and supervisor mode. This results in the 6-bit permission field shown in Table 5-21.

Table 5-21. Request-Type Access Controls

Bit Name	Description
SR	Supervisor can read
SW	Supervisor can write
SX	Supervisor can execute (1)
UR	User can read
UW	User can write
UX	User can execute (1)

(1) IVA_XMC.L1DMPPAXX do not implement these bits.

For each bit, writing 1 permits the access type, and writing 0 denies it. For instance, setting the UX bit to 1 means that user mode can execute from the given page. The DSP megamodule allows specifying all six of these bits separately. For L1P, L1D, and L2 memories, and for EDMA, these bits are defined in IVA_XMC.L1PMPPAk[5:0], IVA_XMC.L1DMPPAk[5:0], IVA_XMC.L2MPPAj[5:0], and TPCC_MPPAG[5:0] and TPCC_MPPAj[5:0], respectively.

NOTE: IVA_XMC.L1DMPPAk do not implement the SX and UX bit, because execution is not possible from L1D memory. Therefore, these bits are reserved and should not be used in these registers.

- Other registers

  The memory protection block records the address of the fault in the peripheral memory protection fault address register (MPFAR). It records the rest of the information about the fault in the peripheral memory protection fault status register (MPFSR); this register is formatted similarly to the MPPA. Software can write to the memory protection fault command register (MPFCR).

  The MPFAR corresponds to the following registers: IVA_XMC.L1PMPFAR for L1P memory, IVA_XMC.L1DMPFAR for L1D memory, IVA_XMC.L2MPFAR for L2 memory, IVA_IDMA.ICFGMPFAR for IDMA, and TPCC_MPFAR for EDMA.

  The MPFSR corresponds to the following registers: IVA_XMC.L1PMPFSR for L1P memory, IVA_XMC.L1DMPFSR for L1D memory, IVA_XMC.L2MPFSR for L2 memory, IVA_IDMA.ICFGMPFSR for IDMA, and TPCC_MPFSR for EDMA.

  Using the MPFSR register, a memory protection fault can be decoded as follows by software:

  – If the LOCAL status bit is set to 1, the request was a local DSP CPU request to its own memories. Otherwise (if the LOCAL status bit is set to 0), the VBUS ID of the faulting requestor is in the MPFSR[15:9] field.
  – The value of the access type field (SR, SW, SX, UR, UW, UX) indicates the type of access that was at fault.

  The MPFAR and MPFSR store information for only one fault. The hardware block holds the fault information until the software clears it by writing to MPFCR.

  The user clears the recorded fault by setting the MPFCR[0] MPFCLR bit to 1. Writing 1 to this bit clears both MPFAR and MPFSR registers. The MPFAR and MPFSR read-only registers do not respond to writes. Once the user clears the fault, the hardware records the next protection violation, and signals an exception when it occurs. Writing 1 to any other bit of the MPFCR has no effect on the memory protection registers. Writing 0 to the MPFCR[0] MPFCLR bit also has no effect.

  The MPFCR corresponds to the following registers: IVA_XMC.L1PMPFCR for L1P memory, IVA_XMC.L1DMPFCR for L1D memory, IVA_XMC.L2MPFCR for L2 memory, IVA_IDMA.ICFGMPFCR for IDMA, and TPCC_MPFCR for EDMA.

- Events generated to DSP megamodule IC block

  Internal events are generated to inform the DSP megamodule module for memory protection:

  – CCMPINT (EVT28) is generated for a TPCC memory protection interrupt.
  – SYS_CMPA (EVT 119) is generated in case of a SYS CPU memory protection fault.
  – PMC_CMPA (EVT120) and PMC_DMPA (EVT121) are generated in case of CPU and DMA memory protection faults, respectively, on PMC.
  – DMC_CMPA (EVT122) and DMC_DMPA (EVT123) are generated in case of CPU and DMA

memory protection faults, respectively, on DMC.
  - UMC_CMPA (EVT124) and UMC_DMPA (EVT125) are generated in case of CPU and DMA memory protection faults, respectively, on UMC.
  - PMC_CMPA (EVT126) is generated in case of a CPU memory protection fault on EMC.

The AID of the DSP appears in the DNUM control register in the CPU. DNUM is the DSP core number register; it is used to identify which DSP subsystem accessed the shared resources. Because there is only one C64x+:

- GEM_DNUM[7:4] always equals 0x0.
- GEM_DNUM[3:0] equals 0x0 because DSP is labeled as CPU0 in the single core system.

Thus, the possible requestors are:

- C64x
- IDMA
- EDMA
- Any device L3 initiator (through the IVA2.2 slave port)

The PrivID (relative to the DNUM register) equals 0. The ID of IVA DMA accesses is always 0x0, because the IVA DMA inherits ID from DSP megamodule. All accesses on the IVA2 slave port to local memories are seen by DSP megamodule as accesses from an external (non-DSP megamodule) initiator.

Thus, the hard-mapped memory protection IDs are:

- AID0, used for IVA DMA
- AID1 to AID5 (not used)
- AIDX, used by the slave port (L3 initiators)
- LOCAL bit, used by DSP loads, stores, and program fetches to memory attached directly to DSP megamodule

5.4.9.2.2 Bandwidth Management

The bandwidth management scheme can be summarized as weighted-priority-driven bandwidth allocation. Each requestor (EDMA, IDMA, CPU, etc.) is assigned a priority level on a per-transfer basis. The programmable priority level has a single meaning throughout the system: there is a total of nine priority levels, where priority 0 is highest and priority 8 is lowest priority. When requests for a single resource contend, access is granted to the highest priority requestor. When contention occurs for multiple successive cycles, a contention counter ensures that the lower priority requestor gets access to the resource every one out of *n* arbitration cycles, where *n* is programmable through the MAXWAIT field. For each identified requestor, a corresponding MAXWAIT field controls the maximum number of cycles that a request can be blocked.

- CPUARB registers: CPU priority and MAXWAIT programming model

The DSP CPU-initiated transfers consist of two components:

1. Program fetch transfers are issued by the CPU to the PMC, and the resulting L1P cache coherency operations (such as alloc/evict) are then issued to the UMC.
2. Data load/store transfers are issued by the CPU to the DMC, and the resulting L1D cache coherency operations (such as alloc/evict/long distance accesses) are then issued to the UMC.

Both program and data requests use the CPUARB values to define the maximum wait time (CPUARB[5:0] MAXWAIT) and priority (CPUARB[18:16] PRI). The effect of the CPUARB values is not just local to PMC or DMC. Priority/maxwait time applies to DMC/PMC cache transactions throughout the DSP megamodule and controls arbitration at each relevant subblock within DSP megamodule. The priority (PRI) and MAXWAIT field is programmed locally in the UMC, DMC, and EMC blocks, through the IVA_UMC.CPUARBU, IVA_DMC.CPUARBD, and IVA_IDMA.CPUARBE PRI and MAXWAIT fields, respectively.

The default value of the CPUARB[18:16] PRI field is set so that CPU transactions are second to highest in the system. This should be a relatively typical value used in most systems, which results in the DSP CPU being granted highest priority most of the time, but a McBSP-type peripheral (typically programmed as the highest priority transfer for sDMA requests) can interrupt the DSP CPU transfers on a nearly immediate basis.

NOTE: CPU priority is software-programmable, but it is considered static (1-time-programmable) for bandwidth management. That is, during normal operation, all DSP CPU transactions are of the same priority. There is no concept of priority inheritance for CPU-initiated transfers as a result of CPU transfer A set at priority X and CPU transfer B set at priority Y. Because CPUARB must be programmed by the CPU, and is therefore a run-time programmation, the effect of the new CPUARB value must take effect for future CPU transfers.

- UCARB registers - User coherence operations

  User coherence operations are broken into two types, block-oriented coherence and global coherence operations. The priority of these requests relative to other requests in the system varies as follows:

  – Global user coherence: Always highest priority
  – Block-oriented coherence: Always lowest priority

Because user coherence priority is fixed, the UCARB registers do not include a priority field. And because global user coherence operations are inherently highest priority, the MAXWAIT field programming applies only to block-oriented user coherence operations, not to global cache operations.

The UCARB[5:0] MAXWAIT field affects only the UMC (IVA_UMC.UCARBU register) and the DMC (IVA_DMC.UCARBD register). The priority values (being fixed) are assumed to be known at both the UMC and the DMC.

NOTE: The UCARB[5:0] MAXWAIT field (and the implied priorities) does not control the priority of coherence operations that result from DMA transactions or CPU transactions.

- IDMAARB registers - IDMA priority programming model

  IDMA supports two active transfers at any time through IDMA channel 0 (used for memory to/from configuration bus transfers) and IDMA channel 1 (used for memory-to-memory transfers). The IDMAARB[5:0]MAXWAIT field is used to determine the maximum wait time for IDMA transactions. The priority level is not programmed through the IDMAARB register. Instead, the priority level is programmed directly through the IDMA control registers. In summary, IDMA transfer priority is:

  – IDMA channel 0: Always highest priority
  – IDMA channel 1: Programmable priority: the IVA_IDMA.IDMA1_COUNT[31:29] PRI field

  For this reason, the IDMAARB registers do not include a priority field. The IDMAARB[5:0] MAXWAIT field affects not only the EMC (IVA_IDMA.IDMAARBE register) but also the UMC (IVA_UMC.IDMAARBU register) and the DMC (IVA_DMC.IDMAARBD register).

NOTE: IDMA channel 0 has no need for priority inheritance, because it is always the highest priority transfer in the system.

However, if an IDMA channel 1 transfer and an IDMA channel 0 transfer are pending at the same instant, but the IDMA channel 1 queue is blocked because of contention with another requestor, the IDMA channel 1 transfer should briefly inherit the priority of the IDMA channel 0 transfer (which is always 0x0) so that the pending dataphase on IDMA channel 1 can complete and the normal priority mechanism can take control.

- SDMAARB registers - Slave DMA priority programming model

The DSP megamodule slave DMA (SDMA) interface can support multiple active transfers at a time. The SDMAARB[5:0] MAXWAIT field controls the maximum wait time for all slave DMA transactions. The priority level is not programmed by the SDMAARB register. Instead, the priority level is dictated by the priority fields of the IVA_TPCC.QUEPRI register.

The SDMAARB[5:0] MAXWAIT field does not affect only the EMC (IVA_IDMA.SDMAARBE register), but also the UMC (IVA_UMC.SDMAARBU register) and the DMC (IVA_DMC.SDMAARBD register).

NOTE: Because of the pipelined nature of the VBUS interface, the DSP megamodule module can have multiple DMA transfers in flight at a time. To avoid priority inversion, the DSP megamodule must not only evaluate the priority of the transfer at the head of the EMC queue(s), but the priority of all transfers that have been accepted/queued on the VBUS interface(s), and of higher priority transfers that are queued in the device-level DMA infrastructure.

- MDMAARBE register - Master DMA priority programming model

  The IVA_IDMA.MDMAARBE[18:16] PRI field controls the submission priority for master DMA transactions (which are a result of cache misses or long-distance accesses to nonconfiguration space) and configuration bus transactions (long-distance accesses to configuration space or IDMA transfers to configuration space).

  The IVA_IDMA.MDMAARBE priority is different from other programmable priorities in the system, in that the priority value does not affect internal arbitration for resources. This PRI[3:0] value is simply used as the VBUS priority value for all transactions initiated by the DMA master interface or memory-mapped register configuration interface.

  Arbitration for the internal half of the transfer depends on the initiator (which could be DSP CPU, PMC, or DMC) or user coherence (UMC), or IDMA, etc. Arbitration for the external half of the transfer is DMA-dependent, and should rely on the Vbus priority, which is copied from the IVA_IDMA.MDMAARBE[18:16] PRI field.

NOTE: Because no internal arbitration results from the IVA_IDMA.MDMAARBE register, there is no need for the MAXWAIT field in this register.

5.4.9.3 SL2 Memory Management

5.4.9.3.1 SL2 Performance Optimizations

To limit the number of accesses through the SL2 interface and to optimize bandwidth, it is recommended that the user access SL2 using, as much as possible, bursts and aligned on burst boundaries. Optimum bandwidth savings can be obtained by doing bursts of 8x32 aligned on 32-byte boundaries.

This can be done using ARM968 (sequencer module) LDM or STM instructions. For details, see the ARM reference manual.

5.4.9.3.2 SL2 Performance Limitations

Accesses through the SL2IF OCP interface to SL2 memory are not intended to be optimized for single reads, but only for bursts. Maximum bandwidth can be obtained using bursts of 8x32b bursts or larger (bursts larger than 8x32 are divided into 8x32 bursts). Generating single requests to the SL2IF interface has two disadvantages:

- Uses a large portion of the SL2 bandwidth, resulting in iME and iLF performance degradation
- Increases dynamic power consumption

In particular, ARM968 instruction fetches generate single requests on the local interconnect. SL2 is not optimized for ARM968 instruction direct fetching. If the ITCM is too small for an ARM968 program, an ARM968 program must be DMAed in from memory (possibly SL2, as DMA accesses are bursted).

5.4.9.3.3 SL2 Illegal Accesses

It is illegal for the user to generate unaligned bursts that span SL2 address range boundaries.

5.4.10 IVA2.2 Power Management

5.4.10.1 Clock Management

5.4.10.1.1 Clock Configuration

The IVA2.2 subsystem receives one single-clock signal from the PRCM, the DPLL2_ALWON.FCLK.

From the DPLL2_ALWON.FCLK functional clock provided by the PRCM, three internal clocks (CD0_CLK, CD1_CLK, and CD2_CLK) are generated by the IVA2.2 DPLL and SYSC modules:

- The frequency of the CD0_CLK clock can be software-tuned with a PRCM register by setting the PRCM.CM_CLKSEL1_PLL_IVA2 and PRCM.CM_CLKSEL2_PLL_IVA2 registers.
- The CD1_CLK clock is always a divide-by-two of the CD0_CLK clock and its frequency cannot be changed by software.
- The CD2_CLK clock is always a divide-by-two of the CD0_CLK clock and its frequency cannot be changed by software.

For a complete description of the PRCM registers discussed in this section, see Chapter 3, *Power, Reset, and Clock Management*.

5.4.10.1.2 Clock Gating

- IVA2.2 subsystem

  The IVA2.2 internal clocks can be hardware-disabled by the PRCM when the MSTANDBY/WAIT handshake protocol occurs. To configure the PRCM so that IVA2.2 internal clocks are hardware-supervised, set the PRCM.CM_AUTOIDLE_PLL_IVA2[2:0] AUTO_IVA2_DPLL field to 0x1.

  When the IVA2.2 subsystem does not require its internal clocks, they can be disabled at the PRCM level by setting the PRCM.CM_FCLKEN_IVA2[0] EN_IVA2 bit to 0.

  For a complete description of these PRCM registers, see Chapter 3, *Power, Reset, and Clock Management*.
- SYSC module

  The IVA2.2 SYSC module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state is operated with no cycle latency penalty.

  The automatic clock-gating feature is enabled by setting the IVA_SYSC.SYSC_SYSCONFIG[0] AUTOIDLE bit to 1 (default value). This feature can be disabled by setting the IVA_SYSC.SYSC_SYSCONFIG[0] AUTOIDLE bit to 0 and making the clock free-running.
- WUGEN module

  The IVA2.2 WUGEN module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no cycle latency penalty.

  Automatic clock gating is enabled by setting the IVA_WUGEN.WUGEN_SYSCONFIG[0] AUTOIDLE bit to 1 (default mode). The clock can be made free-running by setting the IVA_WUGEN.WUGEN_SYSCONFIG[0] AUTOIDLE bit to 0.
- TPCC from EDMA module

  The EDMA (or TPCC) module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-nongated to clock-gated state operates with no cycle latency penalty.

5.4.10.2 Reset Management

In addition to hardware reset signals generated by the PRCM, the IVA2.2 subsystem can be reset by software control.

The three DSP power domain software resets (DSP_RST1, DSP_RST2, and DSP_RST3) are partial warm-reset sources. These software resets map to the PRCM.RM_RSTCTL_IVA2[0] RST1_IVA2 bit, the RM_RSTCTRL_IVA2[1] RST2_IVA2 bit, and the PRCM.RM_RSTCTL_IVA2[2] RST3_IVA2 bit, respectively, in the PRCM register RM_RSTCTRL_IVA2.

Setting these 3 bits to 1 performs a software reset to the IVA2.2 subsystem.

The reset status is logged in the PRCM.RM_RSTST_IVA2[8] IVA2_SW_RST1 read-only bit for IVA2_RST1 software reset, the PRCM.RM_RSTST_IVA2[9] IVA2_SW_RST2 read-only bit for IVA2_RST2 software reset, and the PRCM.RM_RSTST_IVA2[10] IVA2_SW_RST3 read-only bit for IVA2_RST3 software reset.

For a complete description of these PRCM registers, see Chapter 3, *Power, Reset, and Clock Management*.

NOTE: Software reset can be applied only while the IVA2.2 subsystem is in clock-off mode.

5.4.10.3 Power-Down and Wake-Up Management

- DSP megamodule power-down controller (PDC)

  The DSP megamodule embeds a PDC block that allows power-down management by software. Individual DSP megamodule blocks such as DSP CPU, PMC, DMC, EMC, and UMC can be powered off by the PDC.
- This software control is ensured by the IVA_SYS.PDCCMD register:
  - By setting the IVA_SYS.PDCCMD[16] GEMPD bit to 1, the user enables power-down management during idle mode.
  - By setting the IVA_SYS.PDCCMD xMCLOG[1:0] and IVA_SYS.PDCCMD xMCMEM[1:0] fields (x = {P, D, U}), the user controls the XMC clock-gating and standby memory modes. For example, DMC is controlled with the IVA_SYS.PDCCMD[5:4] DMCLOG and IVA_SYS.PDCCMD[7:6] xMCMEM fields.
  - The programming sequence for transition to clock-off state is as follows:

    Before executing the IDLE instruction, the user must perform the following sequence:

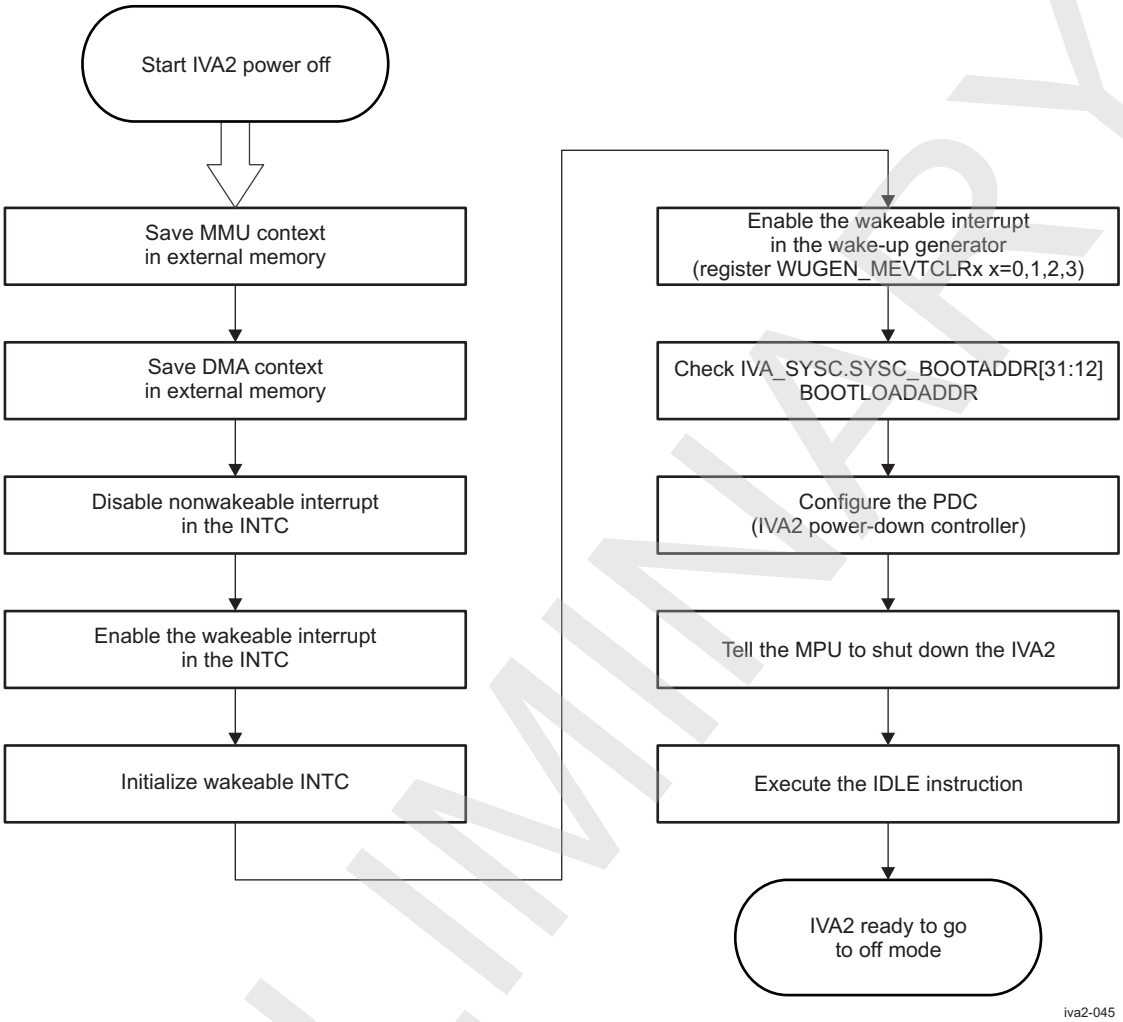
    1. Write 1 to the IVA_SYS.PDCCMD[16] GEMPD bit (standby state); by default, the IVA_SYS.PDCCMD xMCLOG[1:0] and IVA_SYS.PDCCMD xMCMEM[1:0] (x = {P, D, U}) field values are all 0x1, so that module clock gating is enabled and standby mode of memories is statically activated after the IDLE instruction executes.
    2. Mask all interrupts not intended to wake up the IVA2.2 subsystem.
    3. Program the PRCM so that IVA2.2 clocks are cut on IVA2.2 standby. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
    4. Read back all the written registers to ensure write completion.

    The user must also ensure that no other instruction is executed parallel to the IDLE instruction.

    When a clock stop request is asserted, the PDC_INT event (EVT118, see Table 5-3) is generated to the DSP megamodule IC module to inform the DSP CPU to initiate a power-down sequence. For more information about interrupt management, see Section 5.4.8, *Interrupt Management*.
- Programming sequence for transition to power-off state:

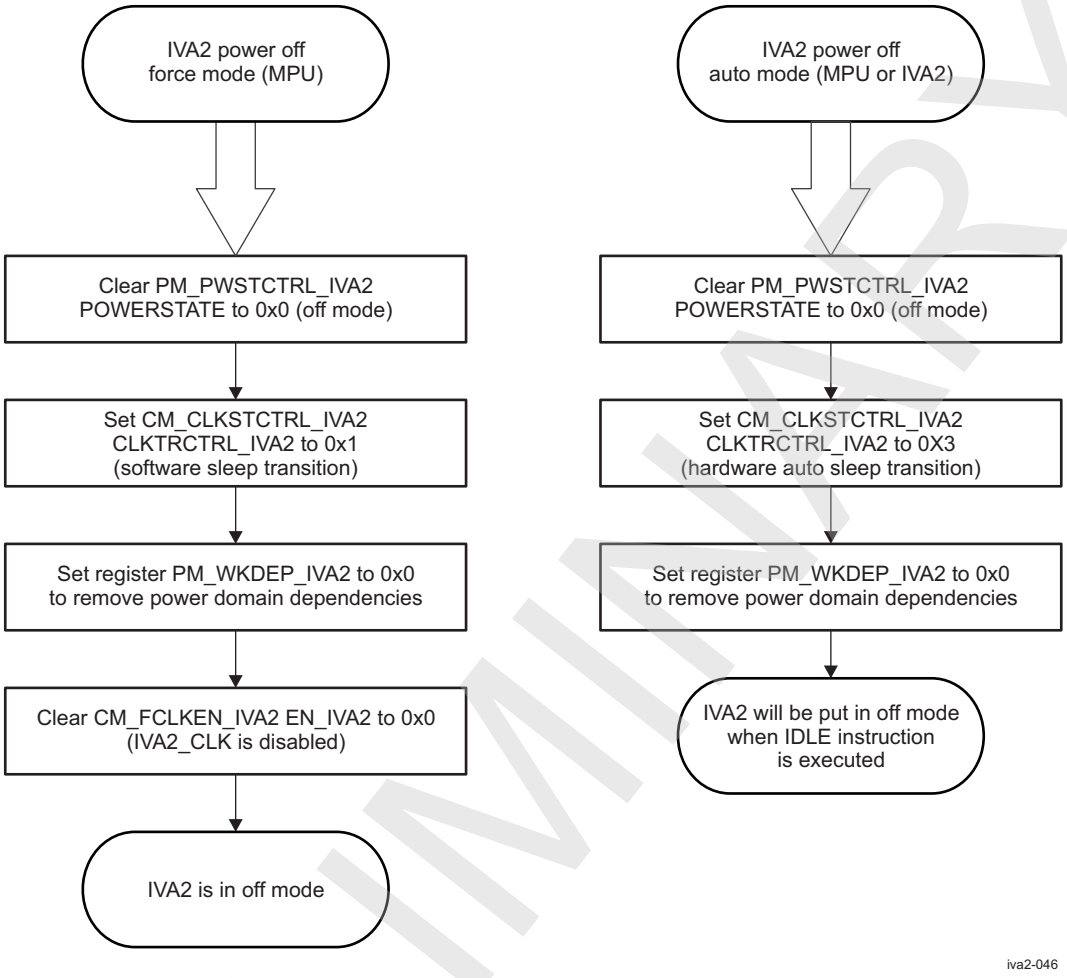
  Before executing the IDLE instruction, the user must perform the sequence shown in Figure 5-34.

Figure 5-34. IVA2 Power Off



The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When IVA2 is ready to go to off mode, there are two ways to completely shut down IVA2 subsystem (see Figure 5-35):

Figure 5-35. IVA2 Power Down

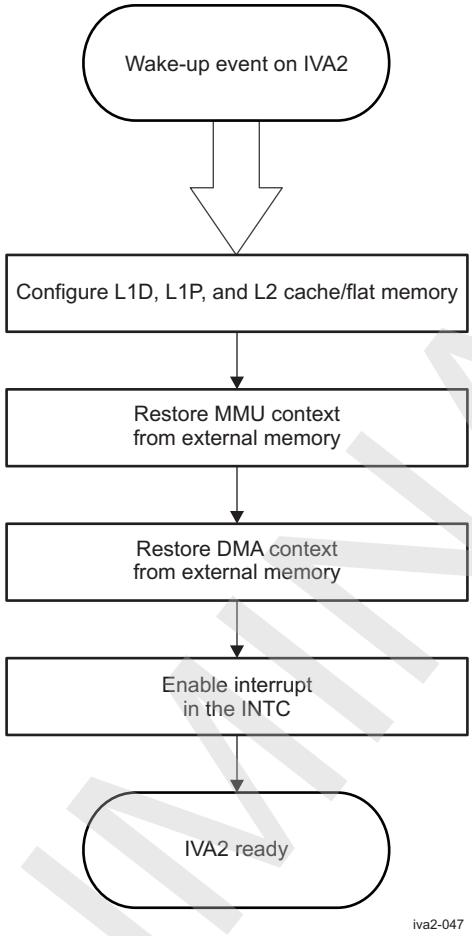


CAUTION

The IVA2 clock must not be stopped manually; otherwise, the WUGEN module inside the IVA2 has no functional clock and cannot wake up the IVA subsystem.

When the IVA2 is shut down, it can be waked up by an external event. The boot code executed after wakeup must include at least the following steps (see Figure 5-36):

Figure 5-36. IVA2 Wake Up



5.4.10.4 Powering Down L2$ Memory While IVA2 is Active

If the L2$ is unused while the DSP is active, the IVA2.2 can completely switch off the 96-KB SRAM attached to the L2$ controller. This typically happens when the DSP is running at a low frequency (for instance, at the same frequency as the SDRAM) where L2$ is not justified. The alternative is to switch off L2$ SRAM completely, losing all L2-cache content and memory-mapped SRAM (from 0x10800000 to 0x1080FFFF). It is impossible to put the SRAM in low-leakage mode and retain data/program while the DSP is active. Also, L2 cache SRAM is the only memory/cache that supports this off mode while DSP is active. L1D and L1P cache SRAM off modes are not supported while DSP is active.

The sequence to enter L2$ off mode while DSP is active follows:

1. Save L2CFG and disable the L2$ by converting L2-cache SRAM to memory-mapped SRAM only (96KB): L2CFG.L2MODE = 0x0.
2. Read back L2CFG to ensure that Step 1 is complete.
3. Save L2MPPAj (j = 0 to 31) and write 0x0 to the L2MPPAj (j = 0 to 31) registers to report access to L2 memory (for debug) and enable associated permission check interrupt and/or exception.
4. Configure the PRCM to switch off L2: PRCM.PM_PWSTCTRL_IVA2.SHAREDL2CACHEFLATONSTATE = 0x0.
5. Read back PRCM.PM_PWSTCTRL_IVA2 to ensure that Step 4 is complete.

After this sequence, the user must not access the L2 memory. If this happens (typically in code under debug), a memory-protection interrupt and/or exception is taken.

The sequence to exit L2$ off mode (while DSP is active) follows:

1. Configure the PRCM to switch on L2: PRCM.PM_PWSTCTRL_IVA2.SHAREDL2CACHEFLATONSTATE = 0x3.
2. Read back PRCM.PM_PWSTCTRL_IVA2 to ensure that Step 1 is complete.
3. Restore L2MPPAj (j = 0 to 31).
4. Restore L2CFG.
5. Read back PRCM.PM_PWSTCTRL_IVA2 to ensure that Step 4 is complete.

NOTE: After this sequence, L2$ is empty and content in L2$-SRAM configured as memory-mapped is lost.

NOTE: This mode does not provide large power savings, but is provided in IVA2.2 as an enabler for power-management software development, anticipating that leakage is a major contributor to power consumption, even in active mode.

5.4.10.5 Video and Sequencer Module Management

5.4.10.5.1 Module Dynamic Power Savings

The video accelerator/sequencer modules implement auto-clock gating to save dynamic power consumption when no activity is locally detected. For some modules (iME, iLF, iVLCD, sequencer, video system controller), it is also possible to disable auto-gating by software. Auto-clock gating has no performance impact.

To optimize local power management, configure the following registers (default values):

- IVA.iME_SYSCONFIG AutoIdle = 1
- IVA.iLF_SYSCONFIG AutoIdle = 1
- IVA.SEQ_SYSCONFIG AutoIdle = 1
- IVA.VIDEOSYSC_SYSCONFIG AutoIdle = 1
- IVA.iVLCD_SYSCONFIG AutoIdle = 1

5.4.10.5.2 System Dynamic Power Savings

For further system dynamic power savings, a module root clock can be independently stopped when the module has no activity.

The root clock of a module can be stopped by writing 0 in the bit associated with that module in the IVA.VIDEOSYSC_CLKCTL register. The clock can be stopped, depending on whether the module is active when it is asked to be stopped. Reading the bit associated with the module in the IVA.VIDEOSYSC_CLKST register lets the user check whether the module clock has effectively been stopped.

Writing 1 in the bit associated with that module immediately restarts clocks if they are stopped, and makes the module operational

When stopping the module root clock, take the following precautions:

- Synchronize with other CPUs/DMAs to determine whether another part of the system requires access to the module.
- Check whether the module has dependencies with other modules.
- Poll the status register in the module to determine whether the module is active.

CAUTION

Invalid configuration of VIDEOSYSC_CLKCTL causes unpredictable results.

For further system dynamic power savings, the sequencer CPU root clock can be independently divided when sequencer activity is reduced.

The root clock of the sequencer CPU can be divided by writing a value different from the value of the NOCLKDIV bit in the VIDEOSYSC_CLKDIV register. There is no software precaution to divide the sequencer CPU clock internally, in terms of traffic or idle conditions. However, this setting is static; that is, it is defined based on whether the sequencer MHz budget must run at full speed, based on a particular task or scenario. The VIDEOSYSC_CLKDIV value must not be changed twice within 16 sequencer clock cycles, or the second request can be ignored. This has no other side effect. Because of the requirement that the setting be static, it is acceptable to make this sequence uninterruptible, pad it with NOPs (or useful operations), or check for change effect, after changing the sequencer clock ratio.

The sequencer CPU clock can be independently divided by 2, 3, or 4, or not divided at all. By default, this clock is not divided.

5.4.11 Error Identification Process

Several mechanisms are available in the IVA2.2 subsystem to report errors at different levels.

5.4.11.1 Error Reporting for IDMA Module

The IDMA has its own error-reporting mechanism. The DSP megamodule implements an error register in EMC (IVA_IDMA.IBUSERR) that latches errors for external invalid transactions on either the DMA (MDMA) bus or the configuration (CFG) bus. Errors are detected on the CFG and MDMA write status or read status interfaces. If an error is received and the corresponding command is an invalid transaction, the IVA_IDMA.IBUSERR[31:29] ERR, IVA_IDMA.IBUSERR[10:8] XID, and IVA_IDMA.IBUSERR[2:0] STAT fields are updated accordingly. An error signaled through a non-0 read status is detected on the read data/status interface or a non-0 write status on the write status interface. Alternately, the EMC records an error if a read or write status response is detected for an unrecognized write ID.

NOTE: The user must ensure that the EMC detects/stores error information only for the first detected error on either the MDMA or CFG bus, regardless of whether it is a read or write status. In other words, a single error register (IVA_IDMA.IBUSERR) is shared by read and write errors and by the MDMA bus and the CFG bus, and only the first error is stored. If a read error and a write error are detected at the same time, the write status error is given higher priority and is latched into the IVA_IDMA.IBUSERR register.

When an error is detected and stored in the IVA_IDMA.IBUSERR register, the EMC_BUSERR event (EVT127, see Table 5-3) is available as a system event that can be selected as either a DSP CPU interrupt or an exception event.

The user can clear latched errors by writing 1 to the IVA_IDMA.IBUSERRCLR[0] CLR bit.

5.4.11.2 Error Reporting for EDMA Module

The TPTC and TPCC blocks of the EDMA module also contain registers to inform the user of a problem during IVA2.2 external DMA communication.

TPCC Block

The TPCC provides a single error interrupt output CCERRINT (EVT38, see Table 5-3) that consolidates the error conditions:

- QDMA missed events (stored in the TPCC_QEMR register)
- DMA missed events (stored in the TPCC_EMR register)
- Transfer completion code error (stored in the TPCC_CCERR[16] TCCERR bit)
- Queue threshold error events (stored in the TPCC_CCERR[n] QTHRXCDn bit, n = {0,1}]

When an error is detected, the CCERRINT event is asserted, because error events do not have enables.

NOTE: The CCERRINT event follows the same conventions as other TPCC interrupt outputs. When the error interrupt condition transitions from a no-errors-are-set state to at least one error set, the error output (CCERRINT) pulses high for one TPCC clock cycle. If additional errors are latched before the original error is cleared by the user, the TPCC does not generate additional interrupt pulses. The software must poll all bits during execution of the ISR, and clear all error conditions, so that subsequent error pulses can be generated by the TPCC block.

Error interrupts can be set and/or reevaluated by writes to the TPCC_EEVAL register.

TPTC Block

The TPTC can also detect several error conditions:

- Read status or write status errors in the TPTCj_ERRSTAT[0] BUSERR status bit
- TR error in the TPTCj_ERRSTAT[2] TRERR status bit
- MMR address error in the TPTCj_ERRSTAT[3] MMRAERR status bit

Errors are recorded in the TPTCj_ERRSTAT register, regardless of whether they are enabled. They can be cleared from the TPTCj_ERRSTAT register only by writing 1 to the corresponding bit of the IVA_TPTCj_ERRCLR register.

The error details register (IVA_TPTCj_ERRDET) contains additional information about the first read status error or write status error detected. Future errors are bit-recorded until the TPTCj_ERRDET register is cleared.

If read status and write status are returned to the TPTC in the same cycle, the read or write status value that has an error (nonzero) is latched in the TPTCj_ERRDET register and the TPTCj_ERRSTAT[0] BUSERR bit is set. If both read and write status are nonzero, the write status is given priority for setting the TPTCj_ERRDET register. The TPTCj_ERRDET register is cleared by writing 1 to the TPTCj_ERRCLR[0] BUSERR bit.

If an error is enabled (by the TPTCj_ERREN register bits), the first occurrence of an enabled error generates a pulsed interrupt to the CPU by the TCERRINT event output (TCERRINT0 with EVT39 for TPTG0 and TCERRINT1 with EVT40 for TPTG1, respectively; see Table 5-3). Subsequent errors do not generate a new pulse until all accumulated errors are cleared by the CPU. The CPU clears bits in the TPTCj_INTSTAT register by writing 1 to the corresponding bit(s) of the TPTCj_NTCLR register.

5.4.11.3 Error Reporting for the L3 Interconnect

L3 interconnect out-of-band errors are also reported by the external L3 interrupt signal (l3_ia_iva2_initSError_o). This signal corresponds to the EVT84 event and is directly connected to the IVA2.2_nIRQ[39] DSP CPU interrupt line. For more information about L3 interconnect error reporting, see Chapter 9, *Interconnect*.

5.4.12 Recommendations for Static Settings

The following static settings are recommended:

- SYSC.SYSC_LICFG0.DMATRUECOMPEN = 1; // DMA last write is nonposted.
- SYSC.SYSC_LICFG0.GEMTRUECOMPEN = 1; // DSP last write is nonposted.
- SYSC.SYSC_LICFG0.GEMBURSTOPTEN = 1; // DSP burst optimization

Ensure that the following setting is carefully set:

- All 2D DMA transfers source and/or destination are to a VRFB view (tiling structure):
  - // DMA 2D burst optimization
  - SYSC.SYSC_LICFG0.DMA2DOPTEN = 1

NOTE: If the preceding condition is not set accurately, setting the DMA2DOPTEN optimization can degrade performance.

NOTE:

1. A supersection type MMU page (16MB) must be defined for that VRFB view.
2. When the SYSC.SYSC_LICFG0.PAGEXINGEN is set to 1, a 2D DMA should not cross a MMU page boundary. When this bit is set, it disables the hardware check mechanism for better performance (but the user should ensure that 2D DMA does not cross MMU pages).

   Therefore, ensure that the following setting is carefully set:
   SYSC.SYSC_LICFG0.PAGEXINGEN = 1.

NOTE: If the preceding condition is not set accurately, setting the PAGEXINGEN optimization can cause undefined results, including deadlock situations.

5.5 IVA2.2 Subsystem Register Manual

Table 5-22 lists the IVA2.2 memory space mapping as seen by the IVA2.2 DSP megamodule.

Table 5-22. Instance Summary

Module Name	Base Address	Size
IC	0x0180 0000	64K bytes
SYS	0x0181 0000	64K bytes
IDMA	0x0182 0000	64K bytes
XMC	0x0184 0000	64K bytes
TPCC	0x01C0 0000	64K bytes
TPTC0	0x01C1 0000	1K byte
TPTC1	0x01C1 0400	1K byte
SYSC	0x01C2 0000	4K bytes
WUGEN	0x01C2 1000	4K bytes
iVLCD[1]	0x0008 0000	8K bytes
SEQ[1]	0x0009 0000	2K bytes
VIDEOSYSC[1]	0x0009 C000	4K bytes
iME[1]	0x000A 0000	4K bytes
iLF[1]	0x000A 1000	4K bytes
IA_GEM	0x000F 8800	1K bytes
IA_EDMA	0x000F 8C00	1K bytes
IA_SEQ	0x000F 9000	1K bytes

(1) These modules are accessible through DSP EFI port, with EFI instruction only. See Section 5.3.4, *Video Accelerator/Sequencer Local Interconnect*.

For more information on the IVA2.2 memory mapping, see Chapter 2, *Memory Mapping*.

NOTE: The MMU2 (IVA2.2 MMU) registers are descibed in Chapter 15, *Memory Management Units*. (The MMU base address is 0x5D00 0000 on the L3 interconnect.)

CAUTION

The IVA2.2 registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

5.5.1 IC Registers

This section provides information about the IC Module. Each register in the module is described in Table 5-24 through Table 5-46.

5.5.1.1 IC Register Mapping Summary

Table 5-23. IC Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

5.5.2 SYS Registers

This section provides information about the SYS Module. Each register in the module is described separately below.

5.5.2.1 SYS Register Mapping Summary

Table 5-48. SYS Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
PDCCMD	RW	32	0x0000 0000	0x0181 0000
REVID	R	32	0x0000 2000	0x0181 2000

5.5.2.2 SYS Register Descriptions

Table 5-49. PDCCMD

Address Offset	0x0000 0000		
Physical address	0x0181 0000	**Instance**	IVA2.2 GEMSYS
Description	Power-Down Command Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															GEMPD	EMCMEM		EMCLOG		UMCMEM		UMCLOG		DMCMEM		DMCLOG		PMCMEM		PMCLOG	

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
16	GEMPD	Power-down during IDLE: GEMPD = 0: Normal operation. Do not power-down CPU or DSP megamodule when CPU is IDLE. GEMPD = 1: Sleep mode. Power-down CPU and DSP megamodule when CPU enters IDLE state	RW	0
15:14	EMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the EMC for powering-down internal memories. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
13:12	EMCLOG	Logic Clock Gating Modes. Determines to what degree the EMC gates its clockinternally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active(pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
11:10	UMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the UMC for powering-down L2 pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1	RW	0x1

Bits	Field Name	Description	Type	Reset
		Write 0x3: Sleep mode 3 - equivalent to sleep mode 1		
9:8	UMCLOG	Logic Clock Gating Modes. Determines to what degree the UMC gates its clockinternally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active(pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
7:6	DMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the DMC for powering-down L1D pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
5:4	DMCLOG	Logic Clock Gating Modes. Determines to what degree the DMC gates its clockinternally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
3:2	PMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the PMC for powering-down L1P pages. 0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
1:0	PMCLOG	Logic Clock Gating Modes. Determines to what degree the PMC gates its clockinternally. 0x0: No clock gating supported beyond leaf clock gating. 0x1: Static clock gating of unused modulesregions when DSP megamodule is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when DSP megamodule is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1

Table 5-70. IDMA1_COUNT

Address Offset	0x0000 0110		
Physical address	0x0182 0110	**Instance**	IVA2.2 GEMIDMA
Description	IDMA Channel 0 Count Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRI			INT	Reserved											FILL	COUNT														Reserved	

Bits	Field Name	Description	Type	Reset
31:29	PRI	Transfer priority. Used for arbitration between CPU and DMA accesses when there are conflicts. PRI = 111b: Low priority PRI = 000b: High priority	RW	0x0
28	INT	CPU interrupt enable INT = 1: Interrupt CPU (IDMA_INT1) on completion INT = 0: Do not interrupt CPU on completion	RW	0
27:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x000
16	FILL	Block fill: FILL = 1: Perform a block fill using the Source address field as the fill value to the memory buffer pointed to by the Destination address field. FILL = 0: Block transfer from the source address to the destination address.	RW	0
15:2	COUNT	16-bit byte count. Must be a multiple of 4 bytes. A transfer count of zero will not transfer any data, but will generate an interrupt if requested in the INT field.	RW	0x0000
1:0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0

5.5.4 XMC Registers

This section provides information about the XMC module, which contains the registers related to the three memory controllers of DSP megamodule: UMC, PMC, and DMC. Each register in the module is described separately below.

5.5.4.1 XMC Register Mapping Summary

Table 5-90. XMC Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
L2CFG	RW	32	0x0000 0000	0x0184 0000

5.5.4.2 XMC Register Descriptions

Table 5-91. L2CFG

Address Offset	0x0000 0000		
Physical address	0x0184 0000	**Instance**	IVA2.2 GEMXMC
Description	L2 cache configuration register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								NUM_MM				Reserved				MMID				Reserved				NOINIT	IP	ID	Reserved			L2CC			L2MODE		

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0
27:24	NUM_MM	Number of megamodules -1 (always 0 for IVA2)	R	0x0
23:20	Reserved	Write 0s for future compatibility. Read returns 0.	R	0x0
19:16	MMID	Megamodule ID (always 0x0 for IVA2)	R	0x0
15:11	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x00
10	NOINIT	No init upon cache config: when written '1', cache config is restored without re-initializing cache context (tags, validity bits) (this is assumed here that the restored cache settings are the same as prior to the execution of the IDLE instruction) when written '0', cache context is re-initialized (cache content is indirectly lost) this bit is always read as 0	W	0
9	IP	Global L1P invalidate (for backward compatibility,deprecated)	W	0
8	ID	Global L1D invalidate (for backward compatibility,deprecated)	W	0
7:5	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x0
4:3	L2CC	L2 cache control 0x0: L2 cache operates normally 0x1: L2 Cache is frozen 0x2: L2 cache is bypassed	RW	0x0
2:0	L2MODE	L2 Configuration Register 0x0: 0KB of L2 Cache 0x1: 32KB of L2 Cache 0x2: 64KB of L2 Cache	RW	0x0

Description	L1D Memory Protection Fault Command Register		
Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																															MPFCLR

Bits	Field Name	Description	Type	Reset
31:1	Reserved	Write 0s for future compatibility. Read returns 0.	W	0x00000000
0	MPFCLR	Write 0: No effect Write 1: Clear fault logged information	W	0

5.5.5 TPCC Registers

This section provides information about the TPCC module. Each register in the module is described separately below.

5.5.5.1 TPCC Register Mapping Summary

Table 5-185. TPCC Register Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
TPCC_PID	R	32	0x0000	0x01C0 0000
TPCC_CCCFG	R	32	0x0004	0x01C0 0004
TPCC_DCHMAPi [1]	RW	32	0x0100 + (0x4*i)	0x01C0 0100 + (0x4*i)
TPCC_QCHMAPj [2]	RW	32	0x0200 + (0x4*j)	0x01C0 0200 + (0x4*j)
TPCC_DMAQNUM0	RW	32	0x0240	0x01C0 0240
TPCC_DMAQNUM1	RW	32	0x0244	0x01C0 0244
TPCC_DMAQNUM2	RW	32	0x0248	0x01C0 0248
TPCC_DMAQNUM3	RW	32	0x024C	0x01C0 024C
TPCC_DMAQNUM4	RW	32	0x0250	0x01C0 0250
TPCC_DMAQNUM5	RW	32	0x0254	0x01C0 0254
TPCC_DMAQNUM6	RW	32	0x0258	0x01C0 0258
TPCC_DMAQNUM7	RW	32	0x025C	0x01C0 025C
TPCC_QDMAQNUM	RW	32	0x0260	0x01C0 0260

5.5.5.2 TPCC Register Descriptions

Table 5-186. TPCC_PID

Address Offset	0x0000		
Physical address	0x01C0 0000	**Instance**	IVA2.2 TPCC
Description	Peripheral ID Register		
Type	R		

31 30	29 28	27 26 25 24	23 22 21 20 19 18 17 16	15 14 13 12 11 10 9 8	7 6	5 4 3 2 1 0
SCHEME	RESERVED	FUNC		RTL	MAJOR	CUSTOM	MINOR

Bits	Field Name	Description	Type	Reset
31:30	SCHEME	PID scheme: Used to distinguish between old ID scheme and current. Spare bit to encode future schemes EDMA uses new scheme, indicated with value of 0x1.	R	0x1
29:28	Reserved	Read returns 0.	R	0x0
27:16	FUNC	Function indicates a software-compatible module family.	R	0x001
15:11	RTL	RTL version	R	0x--
10:8	MAJOR	Major revision	R	0x3
7:6	CUSTOM	Custom revision field: Not used on this version of EDMA.	R	0x0
5:0	MINOR	Minor revision	R	0x--

Reserved	MPEXIST	CHMAPEXIST	Reserved	NUMREGN	Reserved	NUMTC	Reserved	NUMPAENTRY	Reserved	NUMINTCH	Reserved	NUMQDMACH	Reserved	NUMDMACH

Bits	Field Name	Description	Type	Reset
31:26	Reserved	Read returns 0.	R	0x00
25	MPEXIST	Memory Protection Existence MPEXIST = 0: No memory protection. MPEXIST = 1: Memory Protection logic included.	R	1
24	CHMAPEXIST	Channel Mapping Existence CHMAPEXIST = 0: No Channel mapping. CHMAPEXIST = 1: Channel mapping logic included.	R	1
23:22	Reserved	Read returns 0.	R	0x0

Bits	Field Name	Description	Type	Reset
21:20	NUMREGN	Number of MP and Shadow regions	R	0x3
		Read 0x0: 0 Regions		
		Read 0x1: 2 Regions		
		Read 0x2: 4 Regions		
		Read 0x3: 8 Regions		
19	Reserved	Read returns 0.	R	0
18:16	NUMTC	Number of Queues/Number of TCs	R	0x1
		Read 0x0: 1 TC/Event Queue		
		Read 0x1: 2 TC/Event Queue		
		Read 0x2: 3 TC/Event Queue		
		Read 0x3: 4 TC/Event Queue		
		Read 0x4: 5 TC/Event Queue		
		Read 0x5: 6 TC/Event Queue		
		Read 0x6: 7 TC/Event Queue		
		Read 0x7: 8 TC/Event Queue		
15	Reserved	Read returns 0.	R	0
14:12	NUMPAENTRY	Number of PaRAM entries	R	0x3
		Read 0x0: 16 entries		
		Read 0x1: 32 entries (unsupported setting)		
		Read 0x2: 64 entries		
		Read 0x3: 128 entries		
		Read 0x4: 256 entries		
		Read 0x5: 512 entries		
11	Reserved	Read returns 0.	R	0
10:8	NUMINTCH	Number of Interrupt Channels	R	0x4
		Read 0x1: 8 Interrupt channels		
		Read 0x2: 16 Interrupt channels		
		Read 0x3: 32 Interrupt channels		
		Read 0x4: 64 Interrupt channels		
7	Reserved	Read returns 0.	R	0
6:4	NUMQDMACH	Number of QDMA Channels	R	0x2
		Read 0x0: No QDMA Channels		
		Read 0x1: 2 QDMA Channels		
		Read 0x2: 4 QDMA Channels		
		Read 0x3: 6 QDMA Channels		
		Read 0x4: 8 QDMA Channels		
3	Reserved	Read returns 0.	R	0
2:0	NUMDMACH	Number of DMA Channels	R	0x5
		Read 0x0: No DMA Channels		
		Read 0x1: 4 DMA Channels		
		Read 0x2: 8 DMA Channels		
		Read 0x3: 16 DMA Channels		
		Read 0x4: 32 DMA Channels		
		Read 0x5: 64 DMA Channels

Type	W		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																														SET	EVAL

Bits	Field Name	Description	Type	Reset
31:2	Reserved	Write 0s for future compatibility.	W	0x00000000
1	SET	Error Interrupt Set: CPU write of 1 to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of EMR/EMRH, QEMR, or CCERR. CPU write of 0 has no effect.	W	0
0	EVAL	Error Interrupt Evaluate: CPU write of 1 to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the EMR/EMRH, QEMR, or CCERR registers. CPU write of 0 has no effect.	W	0

Address Offset	0x0340 + (0x8*j)
Physical address	0x01C0 0340 + (0x8*j) Instance IVA2.2 TPCC
Description	DMA Region Access enable for bit N in Region i: En = 0: Accesses through Region i address space to Bit N in any DMA Channel Register are not allowed. Reads will return b0 on Bit N and writes will not modify the state of bit N. Enabled interrupt bits for bit N do not contribute to the generation of the TPCC region i interrupt. En = 1: Accesses through Region i address space to Bit N in any DMA Channel Register are allowed. Reads will return the value from Bit N and writes will modify the state of bit N. Enabled interrupt bits for bit N do contribute to the generation of the TPCC region i interrupt.

Table 5-262. TPCC_ER

Address Offset	0x1000		
Physical address	0x01C0 1000	**Instance**	IVA2.2 TPCC
Description	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

Table 5-272. TPCC_CER

Address Offset	0x1018		
Physical address	0x01C0 1018	**Instance**	IVA2.2 TPCC
Description	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

Table 5-274. TPCC_CERH

Address Offset	0x101C		
Physical address	0x01C0 101C	**Instance**	IVA2.2 TPCC
Description	Chained Event Register (High Part): If CERH.En bit is set (regardless of state of EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared through software.

Table 5-276. TPCC_EER

Address Offset	0x1020		
Physical address	0x01C0 1020	**Instance**	IVA2.2 TPCC
Description	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

Address Offset	0x1054		
Physical address	0x01C0 1054	**Instance**	IVA2.2 TPCC
Description	Int Enable Register (High Part): IERH.In is not directly writeable. Interrupts canbe enabled through writes to IESRH and can be disabled through writes to IECRH register. IERH.In = 0: IPRH.In is NOT enabled for interrupts. IERH.In = 1: IPRH.In IS enabled for interrupts.

Table 5-312. TPCC_QER

Address Offset	0x1080		
Physical address	0x01C0 1080	**Instance**	IVA2.2 TPCC
Description	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Table 5-324. TPCC_ER_Rn

Address Offset	0x2000 + (0x200*n) n = 0 to 7		
Physical address	0x01C0 2000 + (0x200*n) n = 0 to 7	**Instance**	IVA2.2 TPCC
Description	Event Register: If ER.En bit is set and the EER.En bit is also set, then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. ER.En bit is set when the input event #n transitions from inactive (low) to active (high), regardless of the state of EER.En bit. ER.En bit is cleared when the corresponding event is prioritized and serviced. If the ER.En bit is already set and a new inactive to active transition is detected on the input event #n input AND the corresponding bit in the EER register is set, then the corresponding bit in the Event Missed Register is set. Event N can be cleared through sw by writing 1 to the ECR pseudo-register.

Table 5-334. TPCC_CER_Rn

Address Offset	0x2018 + (0x200*n) n = 0 to 7		
Physical address	0x01C0 2018 + (0x200*n) n = 0 to 7	**Instance**	IVA2.2 TPCC
Description	Chained Event Register: If CER.En bit is set (regardless of state of EER.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CER.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CER.En bit is cleared when the corresponding event is prioritized and serviced. If the CER.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CER.En cannot be set or cleared through software.

Description Chained Event Register (High Part):
If CERH.En bit is set (regardless of state of EERH.En), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the TC. CERH.En bit is set when a chaining completion code is returned from one of the TPTCs through the completion interface, or is generated internally through Early Completion path. CERH.En bit is cleared when the corresponding event is prioritized and serviced. If the CERH.En bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. CERH.En cannot be set or cleared through software.

Table 5-338. TPCC_EER_Rn

Address Offset	0x2020 + (0x200*n) n = 0 to 7		
Physical address	0x01C0 2020 + (0x200*n) n = 0 to 7	**Instance**	IVA2.2 TPCC
Description	Event Enable Register: Enables DMA transfers for ER.En pending events. ER.En is set based on externally asserted events (through tpcc_eventN_pi). This register has no effect on Chained Event Register (CER) or Event Set Register (ESR). Note that if a bit is set in ER.En while EER.En is disabled, no action is taken. If EER.En is enabled at a later point (and ER.En has not been cleared through SW) then the event will be recognized as a valid TR Sync EER.En is not directly writeable. Events can be enabled through writes to EESR and can be disabled through writes to EECR register. EER.En = 0: ER.En is not enabled to trigger DMA transfers. EER.En = 1: ER.En is enabled to trigger DMA transfers.

Address Offset	0x2080 + (0x200*n) n = 0 to 7		
Physical address	0x01C0 2080 + (0x200*n) n = 0 to 7	**Instance**	IVA2.2 TPCC
Description	QDMA Event Register: If QER.En bit is set, then the corresponding QDMA channel is prioritized vs. other qdma events for submission to the TC. QER.En bit is set when a vbus write byte matches the address defined in the QCHMAPn register. QER.En bit is cleared when the corresponding event is prioritized and serviced. QER.En is also cleared when user writes a 1 to the QSECR.En bit. If the QER.En bit is already set and a new QDMA event is detected due to user write to QDMA trigger location and QEER register is set, then the corresponding bit in the QDMA Event Missed Register is set.

Bits	Field Name	Description	Type	Reset
31	PRIV	Privilege level: Privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable through vbus wdata bus. Is readable through VBus rdata bus. PRIV = 0: User level privilege PRIV = 1: Supervisor level privilege	R	-
30:27	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x-
26:24	PRIVID	Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable through vbus wdata bus. Is readable through VBus rdata bus.	R	0x-
23	ITCCHEN	Intermediate transfer completion chaining enable: 0: Intermediate transfer complete chaining is disabled. 1: Intermediate transfer complete chaining is enabled.	RW	-
22	TCCHEN	Transfer complete chaining enable: 0: Transfer complete chaining is disabled. 1: Transfer complete chaining is enabled.	RW	-
21	ITCINTEN	Intermediate transfer completion interrupt enable: 0: Intermediate transfer complete interrupt is disabled. 1: Intermediate transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)	RW	-
20	TCINTEN	Transfer complete interrupt enable: 0: Transfer complete interrupt is disabled. 1: Transfer complete interrupt is enabled (corresponding IER[TCC] bit must be set to 1 to generate interrupt)	RW	-
19:18	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x-
17:12	TCC	Transfer Complete Code: The 6-bit code is used to set the relevant bit in CER (bit CER[TCC]) for chaining or in IER (bit IER[TCC]) for interrupts.	RW	0x--
11	TCCMODE	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion, A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion, A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .	RW	-
10:8	FWID	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC. 0x0: FIFO width is 8-bit 0x1: FIFO width is 16-bit 0x2: FIFO width is 32-bit 0x3: FIFO width is 64-bit	RW	0x-

Bits	Field Name	Description	Type	Reset
		0x4: FIFO width is 128-bit 0x5: FIFO width is 256-bit		
7:4	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x-
3	STATIC	Static Entry: 0: Entry is updated as normal 1: Entry is static, Count and Address updates are not updated after TRP is submitted. Linking is not performed.	RW	-
2	SYNCDIM	Transfer Synchronization Dimension: 0: A-Sync, Each event triggers the transfer of ACNT elements. 1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements	RW	-
1	DAM	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR, Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	RW	-
0	SAM	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR, Src addressing within an array increments. Source is not a FIFO. 1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	RW	-

SRC																															

Bits	Field Name	Description	Type	Reset
31:0	SRC	Source Address: The 32-bit source address parameters specify the starting byte address of the source. If SAM is set to FIFO mode then the user should program the Source address to be aligned to the value specified by the OPT.FWID field. No errors are recognized here but TC will assert error if this is not true.	RW	0x--------

BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	BCNT : Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum Number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of 0 is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.	RW	0x----
15:0	ACNT	ACNT : number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to TC. An ACNT of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field.	RW	0x----

DBIDX																SBIDX															

Bits	Field Name	Description	Type	Reset
31:16	DBIDX	Destination 2nd Dimension Index: DBIDX is a 16-bit signed value (2s complement) used for destination address modification in between each array in the 2nd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-Sync and AB-Sync transfers.	RW	0x----
15:0	SBIDX	Source 2nd Dimension Index: SBIDX is a 16-bit signed value (2s complement) used for source address modification in between each array in the 2nd dimension. It is a signed value between - 32768 and 32767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-sync and AB-sync transfers.	RW	0x----

Address Offset	0x4014 + (0x20*m)		
Physical address	0x01C0 4014 + (0x20*m)	**Instance**	IVA2.2 TPCC
Description	Link and Reload parameters		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Synced transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not CC-thus BCNTRLD is a dont care field.	RW	0x----

Bits	Field Name	Description	Type	Reset
15:0	LINK	Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (i.e., after count fields are decremented to 0) with a new PaRAM Entry. This is called linking. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the literal byte address of the LINK parameter or the PaRAM base-relative address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (i.e., dont have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (i.e., do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Linkand all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. I.e., a value of 0x3FFE is a non-NULL PaRAM link field.	RW	0x----

DCIDX																SCIDX															

Bits	Field Name	Description	Type	Reset
31:16	DCIDX	Destination Frame Index: DCIDX is a 16-bit signed value (2s complement) used for destination address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when DCIDX is applied, the current array in anA-sync transfer is the last array in the frame, while the current array in a ABsync transfer is the first array in the frame.	RW	0x----

Bits	Field Name	Description	Type	Reset
15:0	SCIDX	Source Frame Index: SCIDX is a 16-bit signed value (2s complement) used for source address modification for the 3rd dimension. It is a signed value between -32768 and 32767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-sync and AB-sync transfers. Note that when SCIDX is applied, the current arraya in an A-sync transfer is the last array in the frame, while the current array in a AB-sync transfer is the first array in the frame.	RW	0x----

Reserved																		DFSTRTPTR		Reserved				ACTV	Reserved				DSTACTV				Reserved		WSACTV	SRCACTV	PROGBUSY

Bits	Field Name	Description	Type	Reset
31:14	Reserved	Read returns 0.	R	0x00000
13:12	DFSTRTPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
11:9	Reserved	Read returns 0.	R	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. ACTV = 0: Channel is idle. ACTV = 1: Channel is busy.	R	1
7	Reserved	Read returns 0.	R	0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter. Read 0x0: FIFO set is empty. Read 0x1: Dst FIFO contains 1 TR Read 0x2: Dst FIFO contains 2 TR Read 0x3: Dst FIFO contains 3 TR	R	0x0

Bits	Field Name	Description	Type	Reset
		Read 0x4: Dst FIFO contains 4 TR		
3	Reserved	Read returns 0.	R	0
2	WSACTV	Write Status Active WSACTV = 0: Write status is not pending. Write status has been received for all previously issued write commands. WSACTV = 1: Write Status is pending. Write status has not been received for all previously issued write commands.	R	0
1	SRCACTV	Source Active State SRCACTV = 0: Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). SRCACTV = 1: Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0
0	PROGBUSY	Program Register Set Busy PROGBUSY = 0: Prog set idle and is available for programming. PROGBUSY = 1: Prog set busy. User should poll for PROGBUSY equal to 0 prior to re-programming the Program Register set.	R	0

Table 5-423. TPTCj_ERRDET

Address Offset	0x12C		
Physical address	0x01C1 012C	**Instance**	IVA2.2 TPTC0
Physical address	0x01C1 052C	**Instance**	IVA2.2 TPTC1
Description	Error Details Register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														TCCHEN	TCINTEN	Reserved		TCC						Reserved				STAT			

Bits	Field Name	Description	Type	Reset
31:18	Reserved	Read returns 0.	R	0x0000
17	TCCHEN	Contains the OPT.TCCHEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
16	TCINTEN	Contains the OPT.TCINTEN value programmed by the user for the Read or Write transaction that resulted in an error.	R	0
15:14	Reserved	Read returns 0.	R	0x0
13:8	TCC	Transfer Complete Code: Contains the OPT.TCC value programmed by the user for the Read or Write transaction that resulted in an error.	R	0x00
7:4	Reserved	Read returns 0.	R	0x0
3:0	STAT	Transaction Status: Stores the non-zero status/error code that was detected on the read status or write status bus. MS-bit effectively serves as the read vs. write error code. If read status and write status are returned on the same cycle, then the TC chooses non-zero version. If both are non-zero then write status is treated as higherpriority. Encoding of errors matches the CBA spec and issummarized here: 0xF = Read 0x0: No Error (should not cause error to be latched) Read 0x1: Read Addressing error Read 0x2: Read Privilege error Read 0x3: Read Timeout error Read 0x4: Read Data error Read 0x7: Read Exclusive-operation failure Read 0x8: No Error (should not cause error to be latched) Read 0x9: Write Addressing error Read 0xA: Write Privilege error Read 0xB: Write Timeout error Read 0xC: Write Data error Read 0xF: Write Exclusive-operation failure	R	0x0

Table 5-445. TPTCj_SACNT

Address Offset	0x248		
Physical address	0x01C1 0248	**Instance**	IVA2.2 TPTC0
Description	Src Actv Set Count		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	B-Dimension count: Number of arrays to be transferred, where each array is ACNT in length. Count Remaining for Src Active Register Set. Represents the amount of data remaining to be read. Initial value is copied from PCNT. TC decrements ACNT and BCNT as necessary after each read command isissued. Final value should be 0 when TR is complete.	R	0x0000

Bits	Field Name	Description	Type	Reset
15:0	ACNT	A-Dimension count: Number of bytes to be transferred in first dimension. Count Remaining for Src Active Register Set. Represents the amount of data remaining to be read. Initial value is copied from PCNT. TC decrements ACNT and BCNT as necessary after each read command isissued. Final value should be 0 when TR is complete.	R	0x0000

Physical address	0x01C2 0040	**Instance**	IVA2.2 SYSC
Description	This register controls various parameters of the IVA2.2 local interconnect network		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															GEMBURSTOPTEN	GEMTRUECOMPEN	Reserved					DMA2DOPTEN	DMATRUECOMPEN	Reserved				Reserved		PAGEXINGEN	Reserved	

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000
16	GEMBURSTOPTEN	DSP megamodule cache-line operation transfers optimizationcontrol: 0: DSP megamodule cache operation transfers are not optimized 1: DSP megamodule cache operation transfers are optimized	RW	0
15	GEMTRUECOMPEN	DSP megamodule program-initiated write-back transfer true completion control: 0: DSP megamodule program-initiated write-back transfer completion is not accurate 1: DSP megamodule program initiated write-back transfer completion is accurate	RW	0
14:10	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x00
9	DMA2DOPTEN	2D transfers optimization control: 0: 2D DMA transfers optimization is disabled 1: 2D DMA transfers optimization is enabled	RW	0
8	DMATRUECOMPEN	DMA write transfer true completion control: 0: DMA write transfer completion is not accurate 1: DMA write transfer completion is accurate	RW	0
7:4	Reserved	Write 0xF for compatibilityRead returns 0xF	RW	0xF
3:2	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0
1	PAGEXINGEN	MMU page crossing enable: 0: Bursts are not allowed to cross 4KB page boundaries 1: Bursts are allowed to cross 4KB page boundaries	RW	0
0	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0

Table 5-484. SYSC_LICFG1

Address Offset	0x048		
Physical address	0x01C2 0048	**Instance**	IVA2.2 SYSC
Description	This register allows controlling various parameters of the IVA2.2 local interconnect network		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																								APINTERVAL							

Bits	Field Name	Description	Type	Reset
31:5	Reserved	Write 0s for future compatibility. Read returns 0.	RW	0x0000000
4:0	APINTERVAL	Control of the Aged Priority (priority inversion) for DMA accesses: When set to 0x0, the aged priority is disabled When set to another value, this controls how often the priority is adjusted: every APInterval cycles, the priority of the port is decreased until the associated request is accepted or the priority of the port equals 0. The priority of the port is reinitialized to the transaction priority each time a new VBUS command is generated, i.e. the last one has been accepted. 0x0: Aged Priority Disabled: There is no aged priority in SCR. DMA transaction keeps the fixed priority defined internally, and has to wait for the bus to be freed by higher priority initiators	RW	0x00

Table 5-486. SYSC_BOOTADDR

Address Offset	0x100		
Physical address	0x01C2 0100	**Instance**	IVA2.2 SYSC
Description	This register defines the physical address of the IVA2 boot loader. This is a copy of the CONTROL_IVA2_BOOTADDR when the IVA2 is released from reset.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTLOADADDR																				Reserved											

Bits	Field Name	Description	Type	Reset
31:12	BOOTLOADADDR	Physical address of the IVA2 boot loader: This is the read-only copy of the CONTROL_IVA2_BOOTADDR when the IVA2 is released fromreset This is an index to a 4K-byte page	R	0x-----
11:0	Reserved	Read returns 0.	R	0x000

Table 5-528. IVLCD_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x0008 0010	**Instance**	iVLCD
Description	This register allows controlling various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITY	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Read returns 0. Write has no effect (write a 0 for forward compatibility)	RW	0x0
8	CLOCKACTIVITY	Clock activity during wake up mode period. 0 - OCP clock can be switched-off.	R	0x0
7:5	RESERVED	Read returns 0. Write has no effect (write a 0 for forward compatibility)	RW	0x0
4:3	SIDLEMODE	Slave interface power management, req/ack control "10" = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of iME	R	0x2
2	RESERVED	read returns 0. write has no effect (write a 0 for forward compatibility)	RW	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger the iME reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	AUTOIDLE	Internal OCP clock gating strategy: 0: OCP clock is free running 1: Automatic OCP clock-gating strategy is applied based on the OCP interface activity	RW	0x1

Table 5-542. VLCD_QIN_ADDR

Address Offset	0x0000 1008		
Physical Address	0x0008 1008	**Instance**	iVLCD
Description	This register sets the input address for the quantization computation.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MEMSEL	RESERVED							ADDR							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0000
15	MEMSEL	Sets the buffer used for the computation 0: IMG BUF A/B 1: IMG BUF1	RW	0x0
14:13	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0
12:0	ADDR	Sets the start address for the computation	RW	0x0000

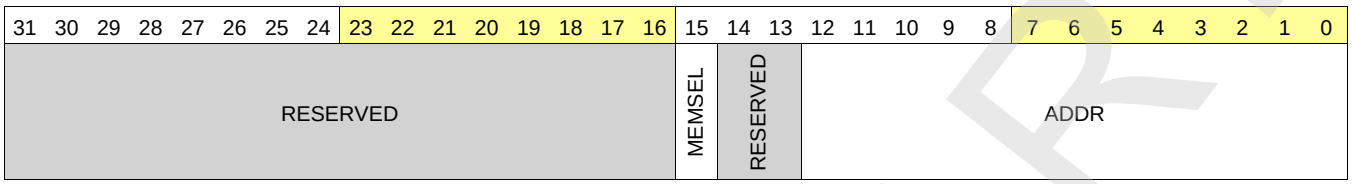
Table 5-544. VLCD_QOUT_ADDR

Address Offset	0x0000 100C		
Physical Address	0x0008 100C	**Instance**	iVLCD
Description	This register sets the output address for the quantization computation.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0000
15	MEMSEL	Sets the buffer used for the computation 0: IMG BUF A/B 1: IMG BUF1	RW	0x0
14:13	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0
12:0	ADDR	Sets the start address for the computation	RW	0x0000

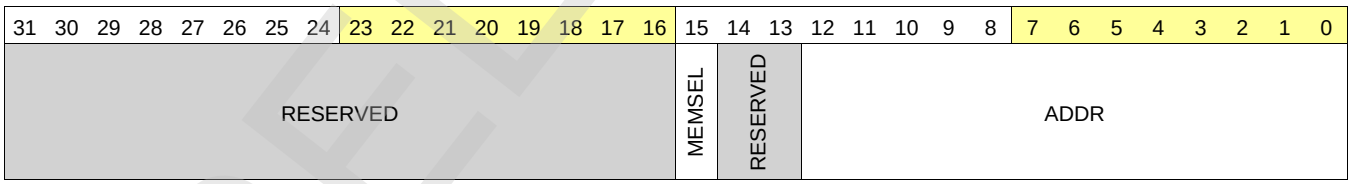
Table 5-546. VLCD_IQIN_ADDR

Address Offset	0x0000 1010		
Physical Address	0x0008 1010	**Instance**	iVLCD
Description	This register sets the input address for the inverse quantization computation.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0000
15	MEMSEL	Sets the buffer used for the computation 0: IMG BUF A/B 1: IMG BUF1	RW	0x0
14:13	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0
12:0	ADDR	Sets the start address for the computation	RW	0x0000

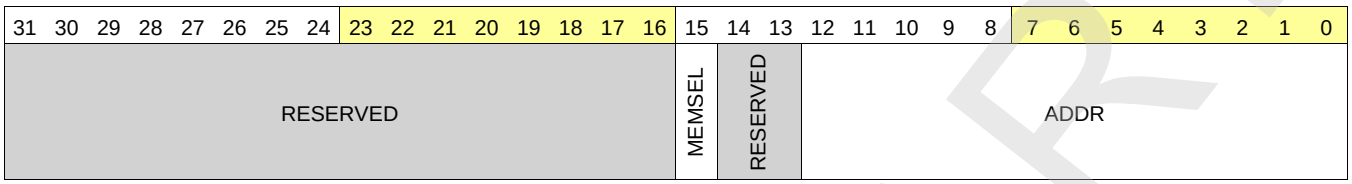
Table 5-548. VLCD_IQOUT_ADDR

Address Offset	0x0000 1014		
Physical Address	0x0008 1014	**Instance**	iVLCD
Description	This register sets the output address for the inverse quantization output address.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0000
15	MEMSEL	Sets the buffer used for the computation 0: IMG BUF A/B 1: IMG BUF1	RW	0x0
14:13	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0
12:0	ADDR	Sets the start address for the computation	RW	0x0000

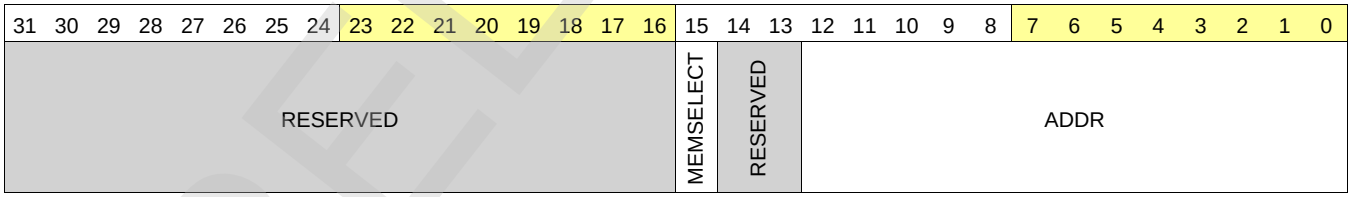
Table 5-550. VLCD_VLCDIN_ADDR

Address Offset	0x0000 1018		
Physical Address	0x0008 1018	**Instance**	iVLCD
Description	This register sets the input address for the variable length coder and decoder operations.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0000
15	MEMSELECT	Sets the buffer used for the computation 0: IMG BUF A/B 1: IMG BUF1	RW	0x0
14:13	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x0
12:0	ADDR	Sets the start address for the computation	RW	0x0000

Table 5-636. VLCD_NRBITSTH

Address Offset	0x0000 1114		
Physical Address	0x0008 1114	**Instance**	iVLCD
Description	This register sets the threshold level of "nrbits" (number of bits) in WMV9.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												NRBITSTH			

Bits	Field Name	Description	Type	Reset
31:4	RESERVED	Write 0s for future compatibility Read returns 0	RW	0x000
3:0	NRBITSTH	Threshold level of "nrbits" (number of bits) in WMV9 decoding. When the "nrbits" gotten from the Huffman table is greater than this threshold value, UVLD error happens. Current VLD algorithm defines the maximum "nrbits" is 6. No need to modify the default value.	RW	0x6

Table 5-704. VIDEOSYSC_CLKCTL

Address Offset	0x0000 0060		
Physical Address	0x0009 C060	**Instance**	VIDEOSYSC
Description	Video accelerator clock control: Writing a 0 forces the module to leave the idle state (modules input clock goes active) Writing a 1 requests the module enter the idle state when no request/commands pending for the module. (Allows module input clock to be stopped). Module automatically exits the idle state and clock starts each time new requests/commands are present. Clock status can be checked in VIDEOSYSC_CLKST register		
Type	W		

Bits	Field Name	Description	Type	Reset
31:6	RESERVED	Reserved Read returns 0	W	0x0
5	SL2IFCLKEN	Clock control of the SL2IF module (iLF and iME modules must be idled as well): 0: Exit idle state and start SL2IF clock 1: Request SL2IF logic to go to idle and stop SL2IF input clock	W	0x0
4	SEQMEMCLKEN	Clock control of the sequencer memory and slave port module: 0: Exit idle state and start SEQ memory and slave port clock 1: Request SEQ slave port logic to go to idle and stop SEQ clock (if SEQ in standby)	W	0x0
3	RESERVED	Reserved Read returns 0	W	0x0
2	IVLCDCLKEN	Clock control of the iVLCD module: 0: Exit idle state and start iVLCD clock 1: Request iVLCD logic to go to idle and stop iVLCD input clock	W	0x0
1	iMECLKEN	Clock control of the iME module: 0: Exit idle state and start iME clock 1: Request iME logic to go to idle and stop iME input clock	W	0x0

Bits	Field Name	Description	Type	Reset
0	iLFCLKEN	Clock control of the iLF module: 0: Exit idle state and start iLF clock 1: Request iLF logic to go to idle and stop iLF input clock	W	0x0

Table 5-713. iME_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x000A 0010	**Instance**	iME
Description	This register allows controlling various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITY	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Read returns 0.	R	0x0
8	CLOCKACTIVITY	Clock activity during wake up mode period. 0 - OCP clock can be switched-off.	R	0x0
7:5	RESERVED	Read returns 0.	R	0x0
4:3	SIDLEMODE	Slave interface power management, req/ack control "10" = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of iME	R	0x2
2	RESERVED	Read returns 0.	R	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger the iME reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy: 0: OCP clock is free running 1: Automatic OCP clock-gating strategy is applied based on the OCP interface activity	RW	0x1

Table 5-754. iLF_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x000A 1010	**Instance**	iLF
Description	This register allows controlling various parameters of the OCP interface		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																							CLOCKACTIVITY	RESERVED			SIDLEMODE		RESERVED	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Read returns 0.	R	0x0
8	CLOCKACTIVITY	Clock activity during wake up mode period. 0 - OCP clock can be switched-off.	R	0x0
7:5	RESERVED	read returns 0.	R	0x0
4:3	SIDLEMODE	Slave interface power management, req/ack control "10" = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of iME	R	0x2
2	RESERVED	read returns 0.	R	0x0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger the iME reset. The bit is automatically reset by the hardware. During reads, it always returns 0.	RW	0x0
0	AUTOIDLE	Internal OCP clock gating strategy: 0: OCP clock is free running 1: Automatic OCP clock-gating strategy is applied based on the OCP interface activity	RW	0x1

Table 5-770. iLF_CPUSTATUSREG

Address Offset	0x0000 05F0		
Physical Address	0x000A 15F0	**Instance**	iLF
Description	CPU Status Register provides information about the progress of the CPU execution		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	DETECTEDENDOFPGM	DETECTEDSTOPSEQ	ENDPGMERROR	OPCODEERROR	WRITEREGERROR	EXECSTATE		PC								CYCLECOUNT															

Bits	Field Name	Description	Type	Reset
31	RESERVED	Read returns 0.	R	0x0
30	DETECTEDENDOFPGM	This bit is set to '1' when, in Debug mode, an EndPgm() instruction or the last instruction of the program buffer has been reached and it is not a LoadInstBuf() instruction. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
29	DETECTEDSTOPSEQ	This bit is set to '1' when a StopSeq() has been issued and the iME is in Halted state. Execution of StopSeq() is postponed to the time when the CPU gets out of the Halted state. This bit is cleared when the StopSeq() command is effectively executed.	R	0x0
28	ENDPGMERROR	This bit is set to '1' when the last instruction of the program buffer is reached and no EndPgm() or LoadInstBuf() instruction have been detected in the program buffer. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
27	OPCODEERROR	This bit is set to '1' when an unknown opcode is decoded from the main program. The following instruction of the sequence is then executed. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
26	WRITEREGERROR	This bit is set to '1' when attempting to write an internal register through an OCP write, while in EXECUTING state. This bit is cleared by a StartSeq() command when in INITIALIZED or COMPLETED state.	R	0x0
25:24	EXECSTATE	Execution States: 00 = Initialized, 10 = Executing, 01 = Halted, 11 = Completed.	R	0x0
23:16	PC	Number of instruction currently executing. Bit #7 is always 0 (PC values range from 0x00 to 0x7f)	R	0x00
15:0	CYCLECOUNT	Total number of cycles executed.	R	0x0000

Camera Image Signal Processor

This chapter describes the camera image signal processor (ISP2P) in the device. ISP2P is backward compatible with ISP2 that is in the legacy device. To facilitate reading in this chapter, ISP2P will be reffered to as ISP.

Topic **Page**

6.1 Camera ISP Overview

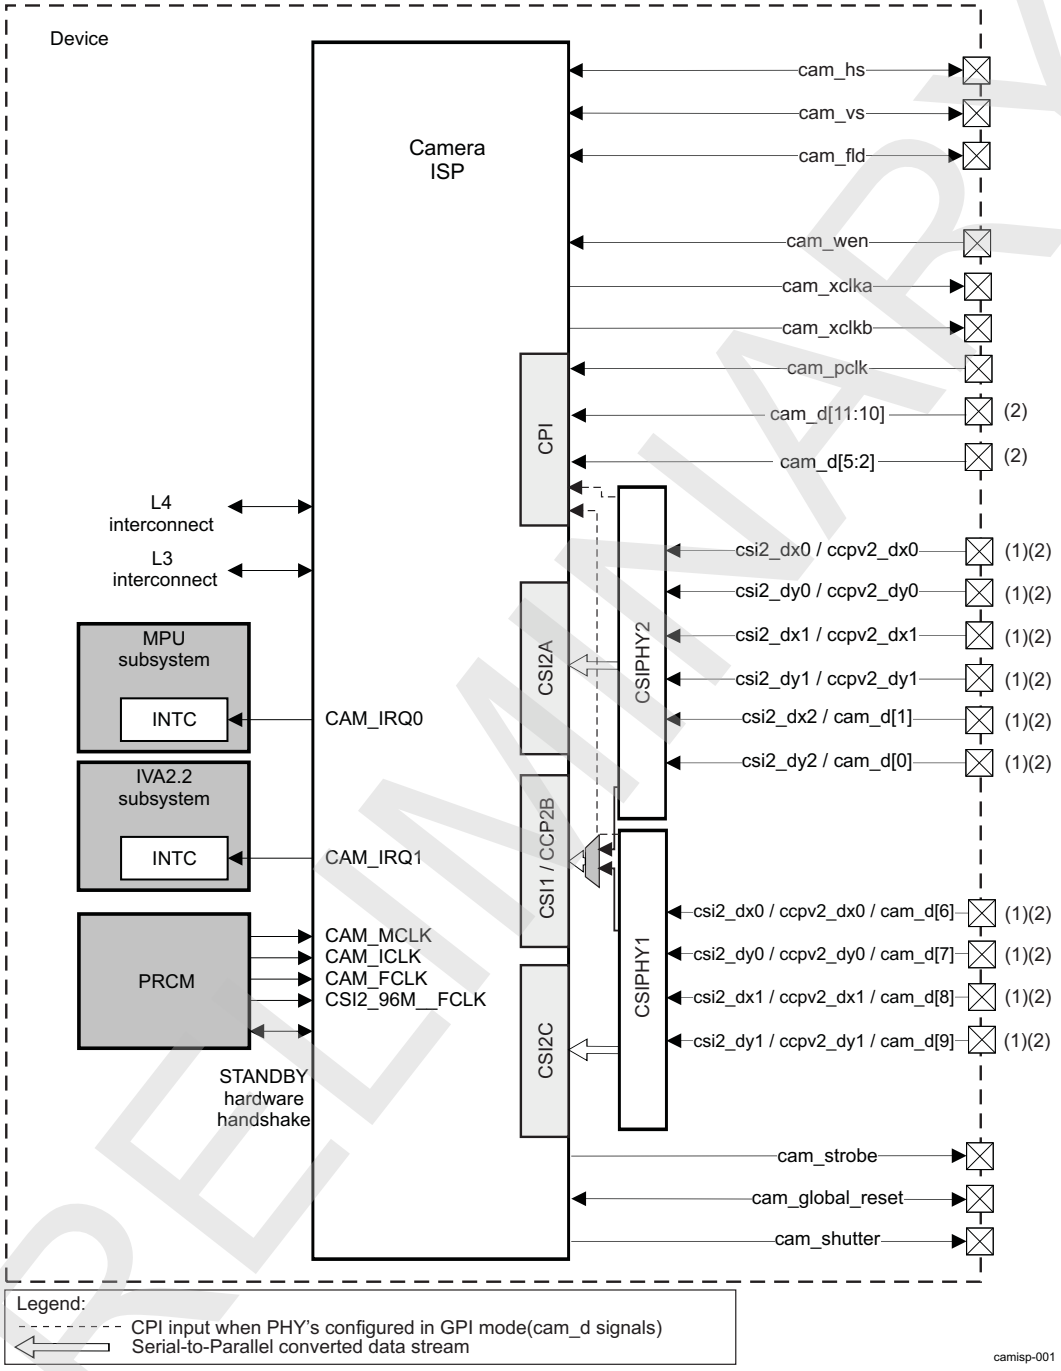
The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the device.

The camera ISP implements three receivers which are named CSI2A, CSI1/CCP2B, and CSI2C. The CSI2A and CSI2C are MIPI® D-PHY CSI2 compatible. The CCP2B (compact camera port) is MIPI® D-PHY CSI1 compatible if used in CSI1 mode. Moreover, on the outside boundaries of camera ISP before the mentioned above receivers, are located two MIPI® D-PHY CSI2 compliant physical layers (CSIPHY1 and CSIPHY2). The two PHY's are MIPI® CSI2 and MIPI® CSI1/SMIA CCP2 compliant. Their purpose is to act as a physical connection between the outside pins for connecting external sensors and the internal receivers. By configuring the outside PHY's and feeding the receivers, the camera ISP supports up to two simultaneous pixel flows from external sensors. Only one of the data flow can use the Video processing hardware while the other must go to memory.

Figure 6-1 shows the camera ISP overview diagram.

Figure 6-1. Camera ISP Overview Diagram



(1) The mode for each PHY can be selected from CSI2, CSI1/CCP2B, and GPI at SCM.CONTROL_CAMERA_PHY_CTRL register. It can also control the connection between one of the PHY's and CSI1/CCP2B receiver via multiplexing.

(2) There is no top-level muxmode (padconf SCM register) control bit for the different camera modes supported by the interfaces. If one or another of the interfaces is enabled, then the camera input signals will be automatically routed to the corresponding ISP receiver depending on the PHY operating mode settings (SCM.CONTROL_CAMERA_PHY_CTRL register).

NOTE: For information about initializing and configuring the CSIPHY, see Section 6.5.2, *Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY*.

6.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
  - Interface with various image sensors:
    - R, G, B primary colors
    - Ye, Cy, Mg, G complementary colors
  - Support for electronic rolling shutter (ERS) and global-release reset shutters
- **CSI1/CCP2B serial interface:** The CSI1/CCP2B receiver is compatible with the SMIA CCP2 specification and the MIPI® CSI1 specification. It supports the following features:
  - Image from sensor
    - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
    - Unidirectional data link
    - 1D and 2D addressing mode
    - Maximum data rate of up to 650 Mbps in CCP2 mode and 208 Mbps in CSI1 mode
    - False synchronization code protection
    - Ping-pong mechanism for double-buffering
    - Support of RGB, RAW, YUV, and JPEG formats
    - DPCM decompression supported
  - Image read from memory
    - RAW formats supported
- **Two MIPI® CSI2 serial interfaces:** The camera ISP implements two MIPI® CSI2 serial interface receivers (CSI2A and CSI2C). The CSI2 receivers enables data transfer at up to 2Gbps. It is based on the MIPI® CSI2 Specification 1.0.
  - Transfer pixels and data received by the CSIPHY1 or CSIPHY2 to the system memory or to the Video processing hardware
  - Uses unidirectional data link
  - Supports up to two data-configurable links, in addition to the clock signaling
  - Maximum data rate of up to 1000M bps per data lane
  - Data merger configuration for CSI2A two data lanes and CSI2C one data lane
  - Error detection and correction by the protocol engine
  - DMA engine integrated with dedicated FIFO
  - Streaming 1-D and 2-D addressing mode (rotation is not supported by the 2D mode)
  - Ping-pong mechanism for double buffering
  - Burst support
  - RAW frame transcoding. Including DPCM and A-law compression
  - JPEG support for unknown length transfer
  - RGB, RAW, and YUV formats supported
  - Storage in progressive mode for interlaced stream (using line numbering)
  - Conversion of the RGB formats
  - Configuration of the associated PHY through Serial Configuration Port (SCP)
  - Fully configurable interface of PHY: position of the clock and data and order of +/- differential signals for each pair.
  - Low power mode using PRCM protocols
- **Parallel interface:** The camera parallel interface (CPI) supports two modes:
  - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-, 10-, 11-, and 12-bit data (if using CCDC inside the Video processing hardware above 10 bit data must be internally converted to 10 bit by the Bridge lane shifter). SYNC mode supports progressive and interlaced image-sensor modules.
  - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. The horizontal and vertical synchronization signals are not provided to the interface.

Instead, the data stream embeds start-of-active video (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations.

- **Video processing hardware:** The Video processing hardware removes the need for expensive camera modules to perform processing functions. It consists of parts: front end and back end:
  - **Video processing front end (VPFE):** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to the video-processing back end for further processing. The Video processing front end is supported by the CCDC module. Signal-processing operations include:
    - Optical clamping
    - Black-level compensation
    - Look-up table (LUT) based faulty pixel correction
    - 2D lens-shading compensation
    - Data formatter
    - Output formatter

    NOTE: Up to 12-bit data at 83 MHz can be transferred from the video port to the ISP submodules. The video processing ISP can treat one pixel every two interconnect clock cycles.
  - **Video processing back end (VPBE):** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
    - **Preview module:** Signal-processing operations include:
      - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
      - Noise reduction and faulty pixel correction
        - Dark frame capture and subtraction
        - Horizontal median filter
        - Programmable filter: 3x3 kernel of the same color
        - Couplet faulty pixel correction
      - Digital gain
      - White balance
      - Programmable color filter array (CFA) interpolation: 5x5 kernel
      - Black adjustment
      - Programmable color correction (RGB to RGB)
      - Programmable gamma correction: 1024 entries for each color
      - Programmable color conversion (RGB to YCbCr 4:4:4)
      - Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
      - Luminance enhancement (non-linear), chrominance suppression and offset

      The preview module can also work from memory to memory.
    - **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling).

      The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.
- **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
  - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
  - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.

The histogram module can also work from memory to memory.

- **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
- **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
- **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
- **Clock generator:** Generates two independent clocks that can be used by two external image sensors
- **Timing control:**
  - Generation clocks passed to the clock generator
  - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
- **Open core protocol (OCP) compliant:**
  - One 64-bit master interface connected to L3
  - One 32-bit slave interface connected to L4

6.2 Camera ISP Environment

6.2.1 Camera ISP Functions

Table 6-1 describes the camera ISP functions and the corresponding application fields.

Table 6-1. Camera ISP Functions

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (If CCDC used inside the Video processing hardware, data must be converted to 10 bit by the Bridge lane shifter). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.
CSI1 / CCP2B serial interface configuration (serial mode)	The camera ISP supports one CCP2B serial interface, compatible MIPI® CSI1.
MIPI® CSI2 serial interfaces (CSI2A and CSI2C) configuration (serial mode)	The camera ISP supports two MIPI® CSI2 serial interface.

NOTE: The two CSI2A and CSI2C receivers and the CSI1/CCP2B receiver can be active simultaneously. Either the CSIPHY1 or CSIPHY2 data can go through the selected interfaces to the video-processing hardware. While the other data directly to memory send by the receiver selected.

The parallel interface is limited to 10 bits when used simultaneously with CSI2A or CSI2C receivers.

The parallel interface cannot be used simultaneously with CSI1/CCP2B receiver.

6.2.3 Camera ISP Connectivity Schemes

The cam_d[9:6] implements the CSIPHY1. The cam_d[1:0] implements the CSIPHY2. Moreover, the PHY's can be configured in GPI, CCP or D-PHY modes from the control module and the SCM.CONTROL_CAMERA_PHY_CTRL control module register. Besides the mode set, from the SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel sets which PHY will be hooked to the CSI1/ CCP2B receiver of the ISP. Some initialization and pad configuration must also be done. For information about initializing and configuring the CSIPHY, see Section 6.5.2, *Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY*.

- In GPI mode, the PHY can be connected to a parallel camera (CAM_D[1:0] in CSIPHY1 and CAM_D[9:6] in CSIPHY2)
- In CCP mode, the PHY can be connected to a CCPV2 camera (strobe/data pairs) or a CSI1 camera (clock/data pairs)
- In D-PHY mode, the PHY can be connected to a CSI2 camera (2 or 1 data lane in CSIPHY1 and 1 data lane only in CSIPHY2)

Table 6-3. Camera ISP Connectivity Schemes

(4) CSI1/CCP2B Interface in blue
(5) Limited: Some data/clock lines connected
(6) CSI2C Interface in green
(7) Full: All data/clock lines connected
(8) Limited: Some data/clock lines connected

NOTE:

- If the parallel camera sensor is the only sensor connected to one CSIPHY, the SCM.CONTROL_CAMERA0_PHY_CAMMOD and SCM.CONTROL_CAMERA1_PHY_CAMMOD bits must be set to 0x11 (that is, GPI mode).
- If the parallel camera sensor and the other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding CSI2_COMPLEXIO_CFG1.DATAx_POSITION bit must be set to 0x0 for the lane used in GPI mode.

6.2.4 Camera ISP Protocols and Data Formats

6.2.4.1 Camera ISP Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 12-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12 bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on cam_d, where one pixel is sampled for every cam_pclk rising edge (or falling edge, depending on the configuration of cam_pclk polarity). For more information, see Section 6.4.

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (cam_hs) and vertical synchronization (cam_vs). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

NOTE: For correct operation, the clock cam_pclk must run during blanking periods (cam_hs and cam_vs inactive). cam_pclk must start before sending cam_d and start cam_vs and cam_hs.

Figure 6-2 and Figure 6-3 show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

Figure 6-2. Camera ISP Synchronization Signals and Frame Timing in SYNC Mode

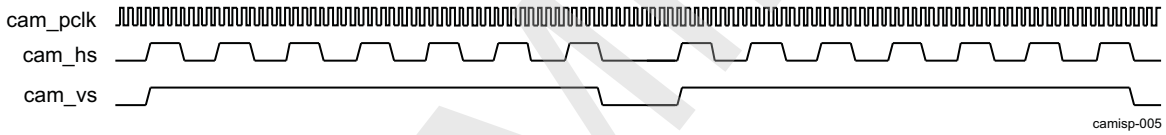

Figure 6-3. Camera ISP Synchronization Signals and Data Timing in SYNC Mode

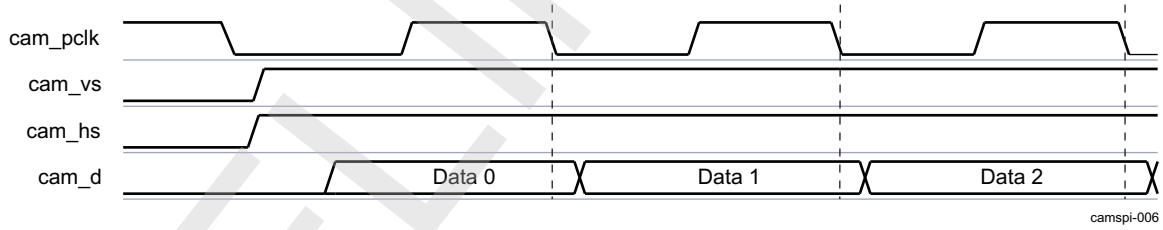
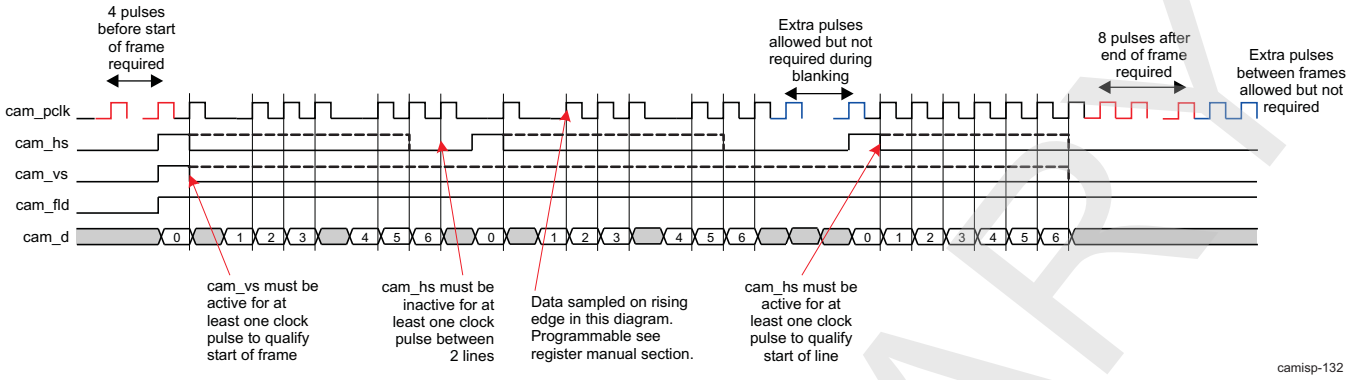


NOTE: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information; 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 6-4 shows the timing diagram of the SYNC move clock gating.

Figure 6-4. Camera ISP SYNC Mode Clock Gating



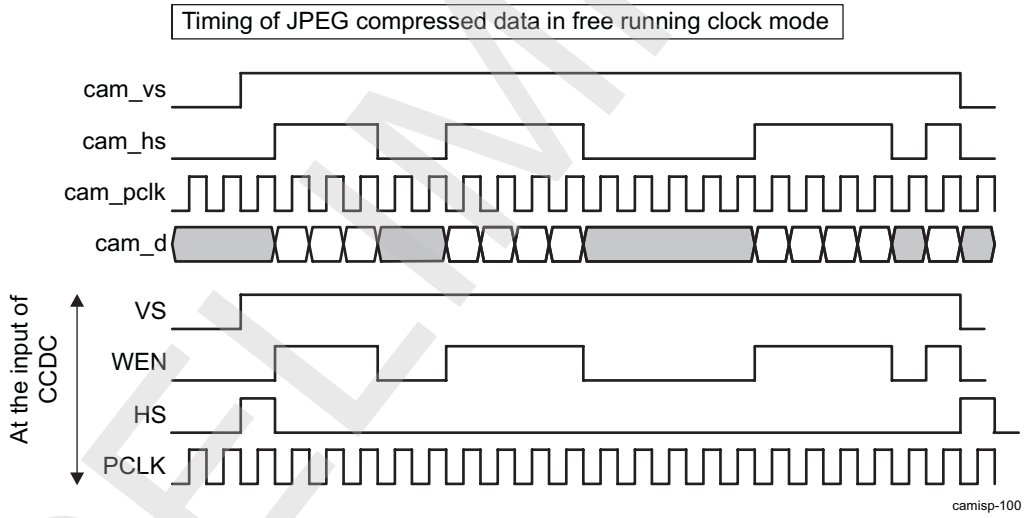
6.2.4.2 Camera ISP Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

To use this mode, set the ISP_CTRL [30] JPEG_FLUSH bit.

Figure 6-5 shows timing diagrams for an JPEG stream.

Figure 6-5. Camera ISP JPEG Stream Timing Diagrams



CAUTION

The bridge cannot be used for JPEG sensor connections.

6.2.4.3 Camera ISP ITU-R BT.656 Protocol and Data Formats (8, 10 Bits)

CAUTION

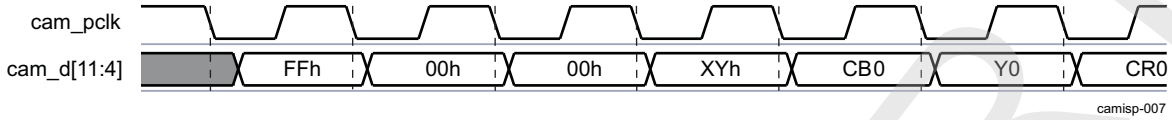
The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 6-6 shows the data timing diagram with embedded synchronization signal.

Figure 6-6. Camera ISP Data Timing With Embedded Synchronization Signals (8-Bit Case)



In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam_hs and cam_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (See the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 6-4 lists the video timing reference codes for SAV and EAV.

Table 6-4. Camera ISP Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 6-5 contains a description of the F, V, and H signals.

Table 6-5. Camera ISP F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the CCDC_REC656IF [1] ECCFVH bit.

NOTE: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

Table 6-6 lists the F, V, and H protection (error-correction) bits.

Table 6-6. Camera ISP F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in Table 6-7 when CCDC_SYN_MODE [11] PACK8 is enabled.

Table 6-7. Camera ISP BT.656 Mode Data Format in SDRAM

8 bit x 4	Pixel3 (Y1/Cr0)	Pixel2 (Cr0/Y1)	Pixel1 (Y0/Cb0)	Pixel0 (Cb0/Y0)
	Bit 31			Bit 0

NOTE: The CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

6.2.4.4 Camera ISP CSI1/CCP2 Protocol and Data Formats

The CSI1/CCP2B receiver supports two protocols:

- MIPI® CSI1 protocol
- CCP2 protocol

The MIPI® CSI1 protocol is compatible with the CCP2 protocol with the following constraints:

- Class 0 CCP2 sensors are used: Data/clock
- No RAW6 or RAW7 data types
- No CRC code generation
- Only one logical channel: Channel 0
- No DPCM

This section describes CSI1/CCP2B protocol and data formats. Table 6-8 describes the I/O for serial interface CSI1/CCP2B.

Moreover, the CSI1/CCP2B receiver is a serial interface to an image sensor. Data is taken from pins and through the configured associated PHY taken to the receiver (for information about initializing and configuring the CSIPHY, see Section 6.5.2.2, *Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver*). The receiver on its side, can send data to the Video processing hardware or memory.

The CSI1/CCP2B receiver interface has several image-data operating modes, summarized in Table 6-8.

Table 6-8. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

CCP2_LCx_CTRL[7:3] Format	CCP2B Data Format	OCP Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Width Constraint: Must Be a Multiple of n Pixels	Storage Increase Versus Packed	2D Mode Availability (1)	Comments
0x0	YUV422 big endian	16	8	N/A	Yes	
0x1	YUV422 little endian	16	8	N/A	Yes	
0x2	YUV420	12	32	N/A	No	
0x3	YUV4:2:2 + VP	N/A, data are sent to VP	2	N/A	N/A	
0x3	RAW8 + VP	N/A, data are sent to VP	4	N/A	N/A	
0x4	RGB444 + EXP16	16	8	N/A	Yes	
0x5	RGB565	16	8	N/A	Yes	
0x6	RGB888	24	16	N/A	No	
0x7	RGB888 + EXP32	32	4	N/A	Yes	
0x8	RAW6 + EXP8	8	16	33%	No	CCP2 only
0x9	RAW6 + DPCM10 + EXP16	16	8	167%	No	DPCM decompression CCP2 only
0xA	RAW6 + DPCM10 + VP	N/A, data are sent to VP	16	N/A	N/A	DPCM decompression CCP2 only
0xB	RAW10 -> RAW6 DPCM	6	64	40%	No	DPCM compression CCP2 only
0xC	RAW7 + EXP8	8	16	14%	No	CCP2 only
0xD	RAW7 + DPCM10 + EXP16	16	8	129%	No	DPCM decompression CCP2 only
0xE	RAW7 + DPCM10 + VP	N/A, data are sent to VP	32	N/A	N/A	DPCM decompression CCP2 only
0xF	RAW10 -> RAW6 DPCM + EXP8	8	16	20%	No	DPCM compression CCP2 only
0x10	RAW6	6	64	N/A	No	CCP2 only
0x10	RAW7	7	128	N/A	No	CCP2 only
0x10	RAW8	8	16	N/A	No	
0x11	RAW8 + DPCM10 + EXP16	16	8	100%	No	DPCM decompression CCP2 only
0x12	RAW8 + DPCM10 + VP	N/A, data are sent to VP	4	N/A	N/A	DPCM decompression CCP2 only
0x13	RAW10 -> RAW7 DPCM	7	128	30%	No	DPCM compression CCP2 only
0x14	RAW10	10	64	N/A	No	
0x15	RAW10 + EXP16	16	8	60%	No	
0x16	RAW10 + VP	N/A, data are sent to VP	16	N/A	N/A	

(1) If data bigger than 10 bits and ment to be used by the CCDC, Bridge lane shifter must be configured for internal conversion to 10 bits.

Table 6-8. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints (continued)

CCP2_LCx_CTRL[7:3] Format	CCP2B Data Format	OCP Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Width Constraint: Must Be a Multiple of n Pixels	Storage Increase Versus Packed	2D Mode Availability (1)	Comments
0x17	RAW10 -> RAW7 DPCM + EXP8	8	16	20%	No	DPCM compression CCP2 only
0x18	RAW12	12	32	N/A	No	
0x19	RAW12 + EXP16	16	8	33%	No	
0x1A	RAW12 + VP	N/A, data are sent to VP	8	N/A	N/A	
0x1B	RAW10 -> RAW8 DPCM	8	16	20%	No	DPCM decompression CCP2 only
0x1C	JPEG, 8-bit data	N/A	N/A	N/A	No	
0x1D	JPEG, 8-bit data + FSP	N/A	N/A	N/A	No	
0x1E	RAW10 -> RAW8	8	16	20%	No	Data right shift

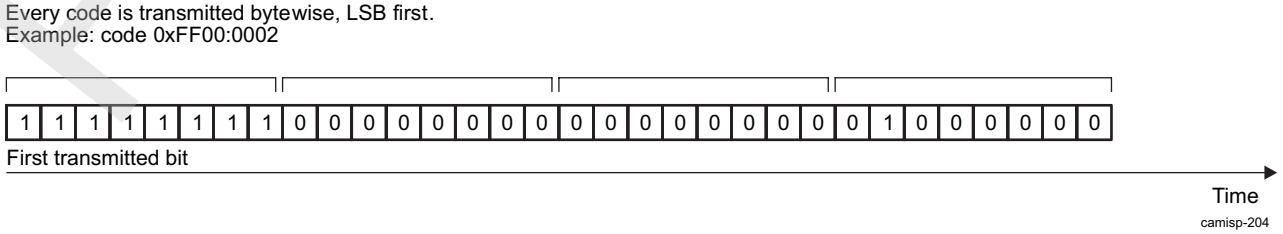
NOTE:

- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros
  CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
  For RGB444 + EXP16:
  - data_out[31:28]=ALPHA[3:0] and data_out[27:16] = RGB444
  - data_out[15:12]=ALPHA[3:0] and data_out[11:0] = RGB444
- EXP32 = Data expansion to 32 bits, padding with alpha
  CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
  For RGB888 + EXP32: data_out[31:24]=ALPHA[7:0] and data_out[23:0]=RGB888
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the Video processing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the Video processing hardware. The behavior of the Video processing hardware is unpredictable if several logical channels to it are enabled simultaneously.

The preamble 0xFF0000 is fixed by construction and must not be modified. However, the CSI1/CCP2B receiver programming model allows the synchronization code identifier to be overwritten: bits 0 to 3.

Every code is transmitted bytewise, least-significant bit (LSB) first. For example, the code 0xFF00:0002 transmitted from the image sensor corresponds to the following bitstream: 11111111 - 00000000 - 00000000 - 01000000. Every default code starts with a set of eight 1s and sixteen 0s that are never received in pixel data. This means that content having eight 1s and sixteen 0s is not allowed. Figure 6-7 shows an example of 0xFF00 0002 transmission.

Figure 6-7. Camera ISP Example of 0xFF00 0002 Transmission



6.2.4.4.1 Camera ISP CSI1/CCP2 Pixel Data Format

This section summarizes how the CSI1/CCP2B pixel data formats are transmitted over the serial interface and how the pixels are reconstructed, stored in memory, or passed to the video port.

The CSI1/CCP2B receiver can cope with all data formats if the data line length sent through the associated PHY is a multiple of 32 bits. This condition is required for the CSI1/CCP2B receiver to work correctly.

However, some data formats impose stronger line-length constraints to correctly finish pixel reconstruction at the end of the lines. If the additional constraints are not respected:

- Only the last reconstructed pixels in every line are erroneous. The missing bits are replaced with 0s to perform pixel reconstruction.
- The FW_IRQ interrupt is triggered.

6.2.4.4.1.1 Camera ISP CSI1/CCP2 YUV Pixel Data Formats

The YUV422 data format can be stored to memory in little- or big-endian format. The line length sent through the associated PHY must be a multiple of 32 bits.

YUV422 data format can also be sent to the video port.

YUV422 + VP is used to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP. Figure 6-8 and Figure 6-9 show big-endian and little-endian YUV422 format, respectively.

Figure 6-8. Camera ISP CSI1/CCP2 YUV422 Big Endian

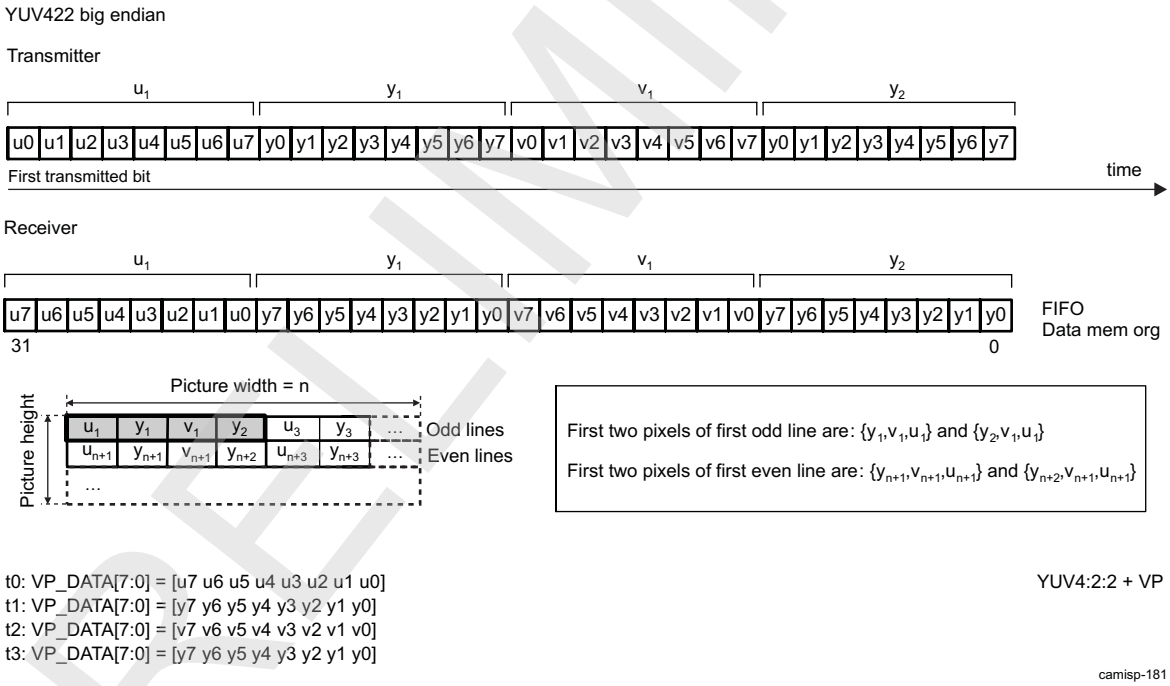


Figure 6-9. Camera ISP CSI1/CCP2 YUV422 Little Endian

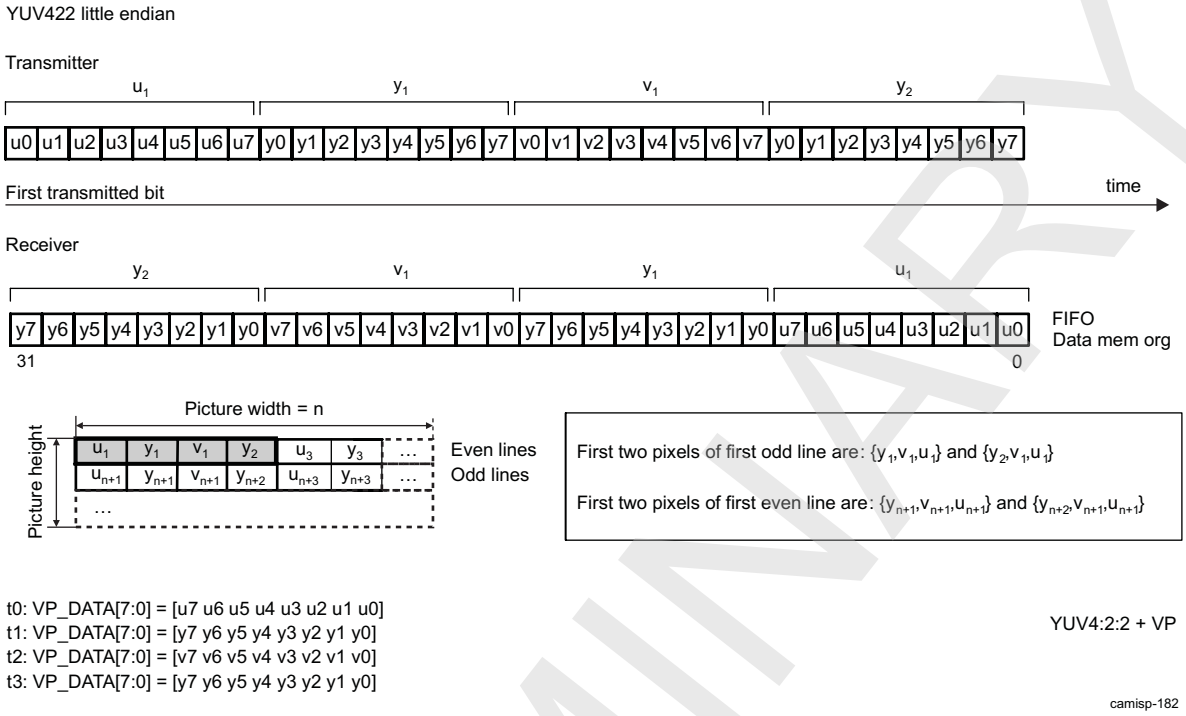
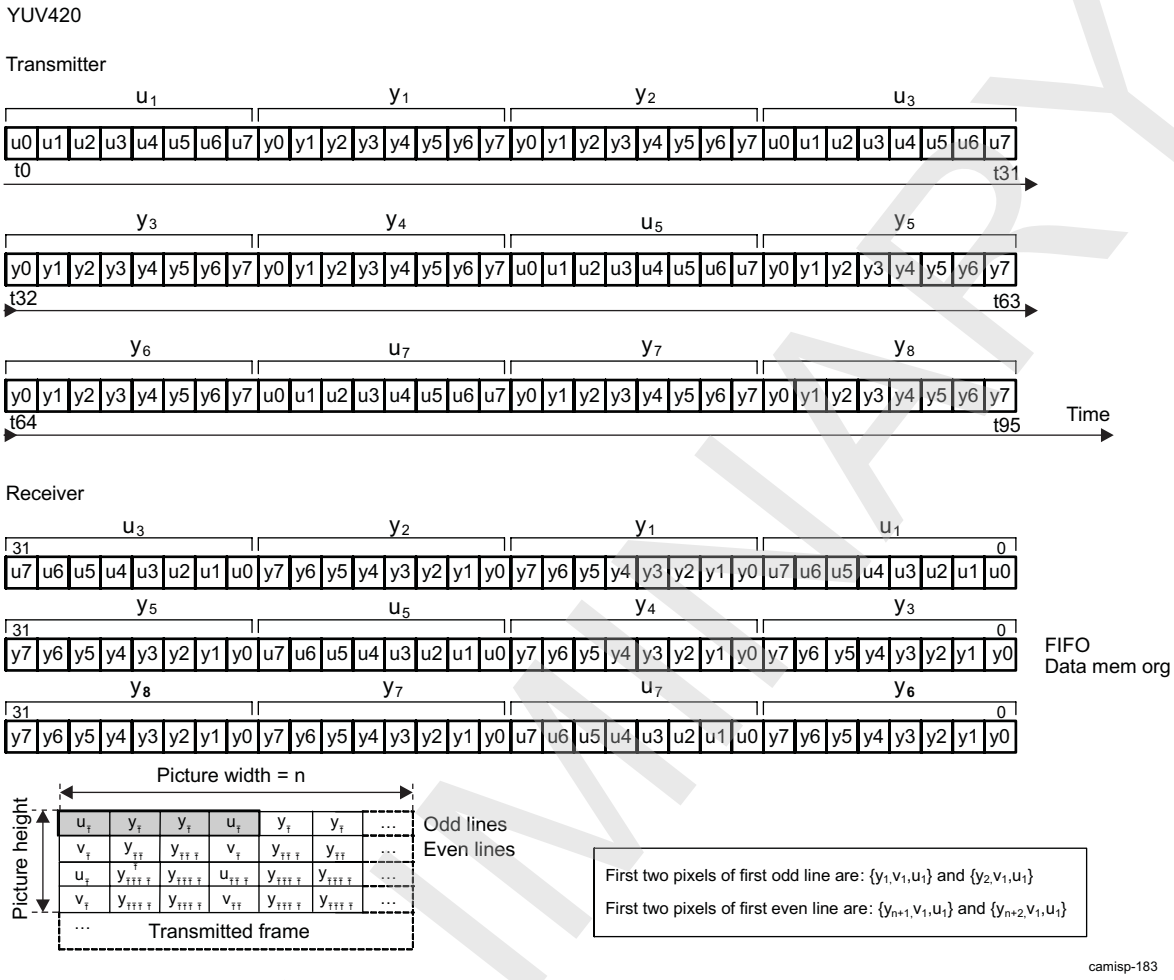


The line length sent through the associated configured PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in Figure 6-10.

Figure 6-10. Camera ISP CSI1/CCP2 YUV420



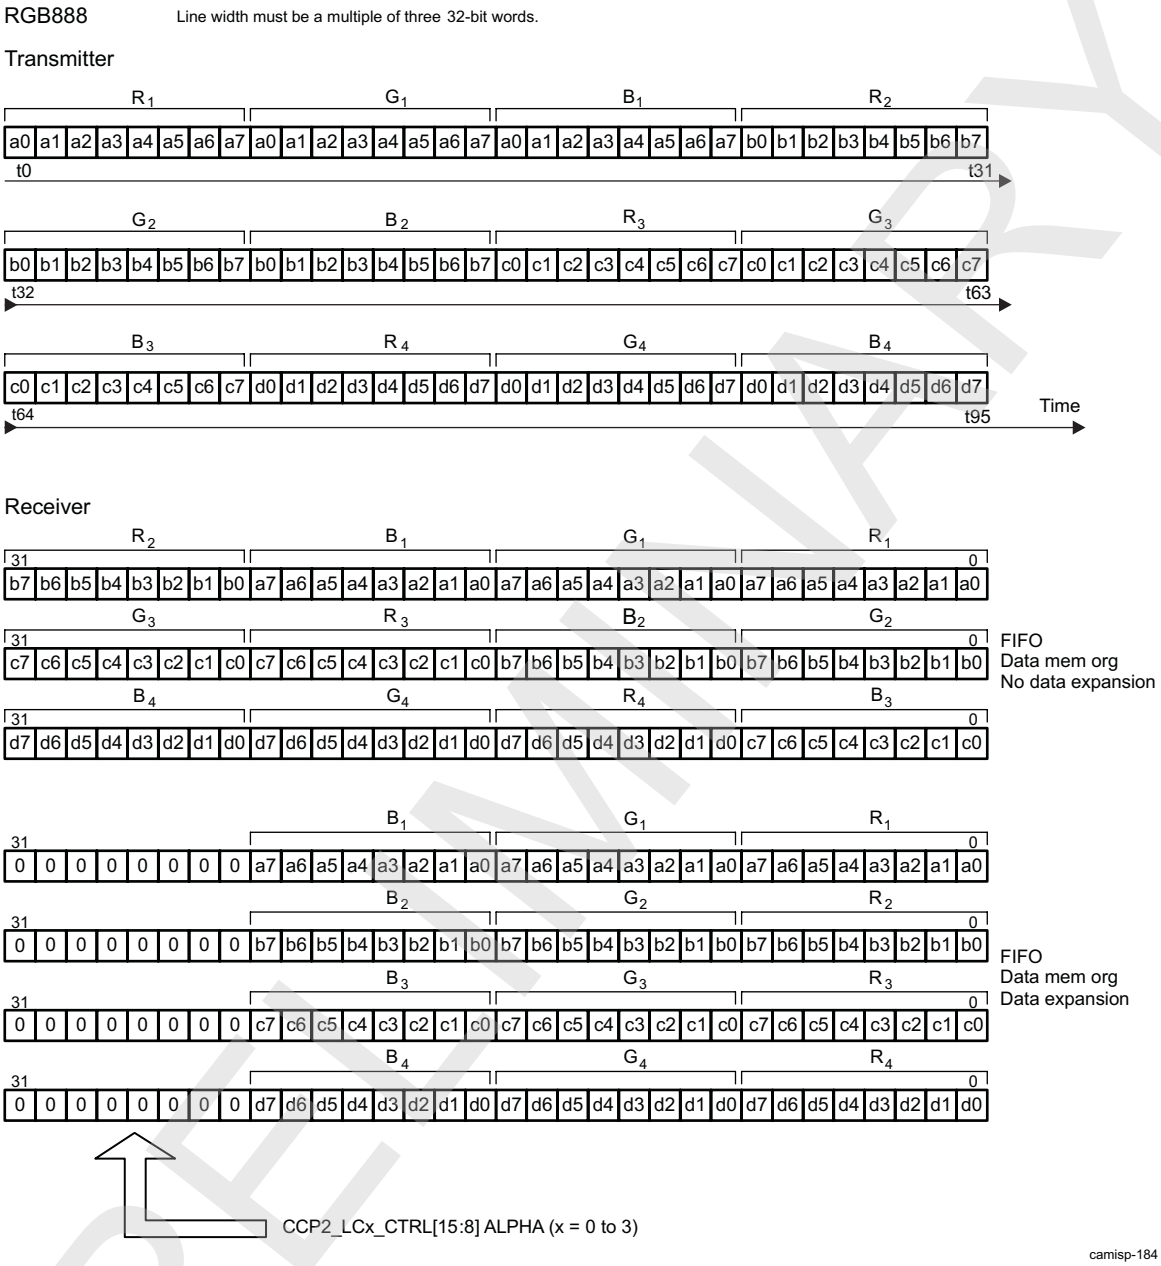
6.2.4.4.1.2 Camera ISP CSI1/CCP2 RGB Pixel Data Formats

RGB888 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction.

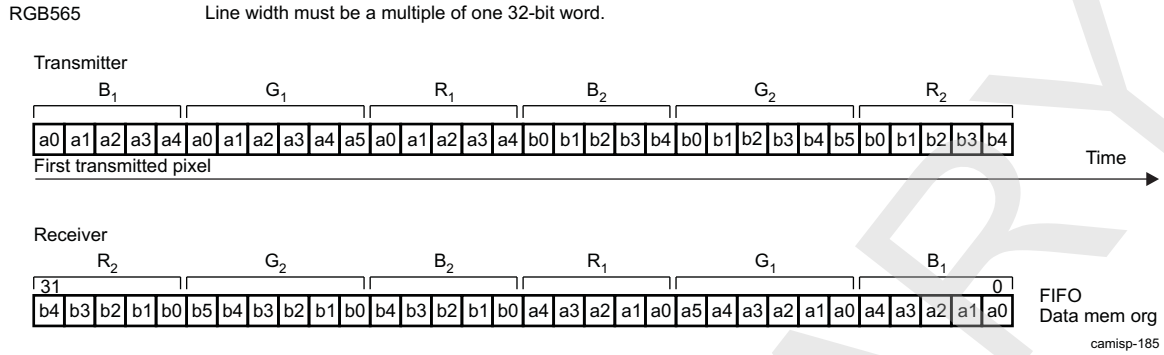
Figure 6-11 shows an example of RGB888 format.

Figure 6-11. Camera ISP CSI1/CCP2 RGB888



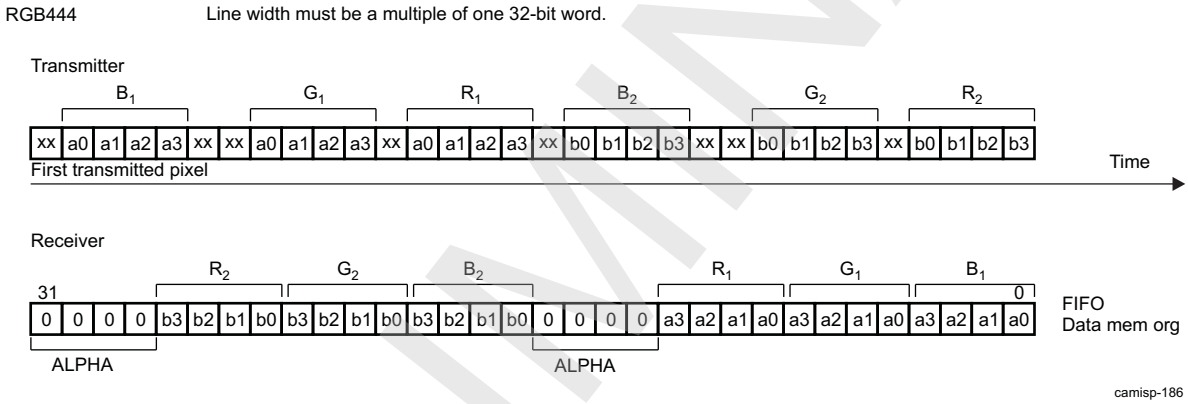
For RGB565, the line length sent through the associated PHY is a multiple of 32 bits (see Figure 6-12).

Figure 6-12. Camera ISP CSI1/CCP2 RGB565



RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits (see Figure 6-13).

Figure 6-13. Camera ISP CSI1/CCP2 RGB444



6.2.4.4.1.3 Camera ISP CSI1/CCP2 RAW Bayer RGB Pixel Data Formats

6.2.4.4.1.3.1 Camera ISP CSI1/CCP2 RAW6 (CCP2 Only)

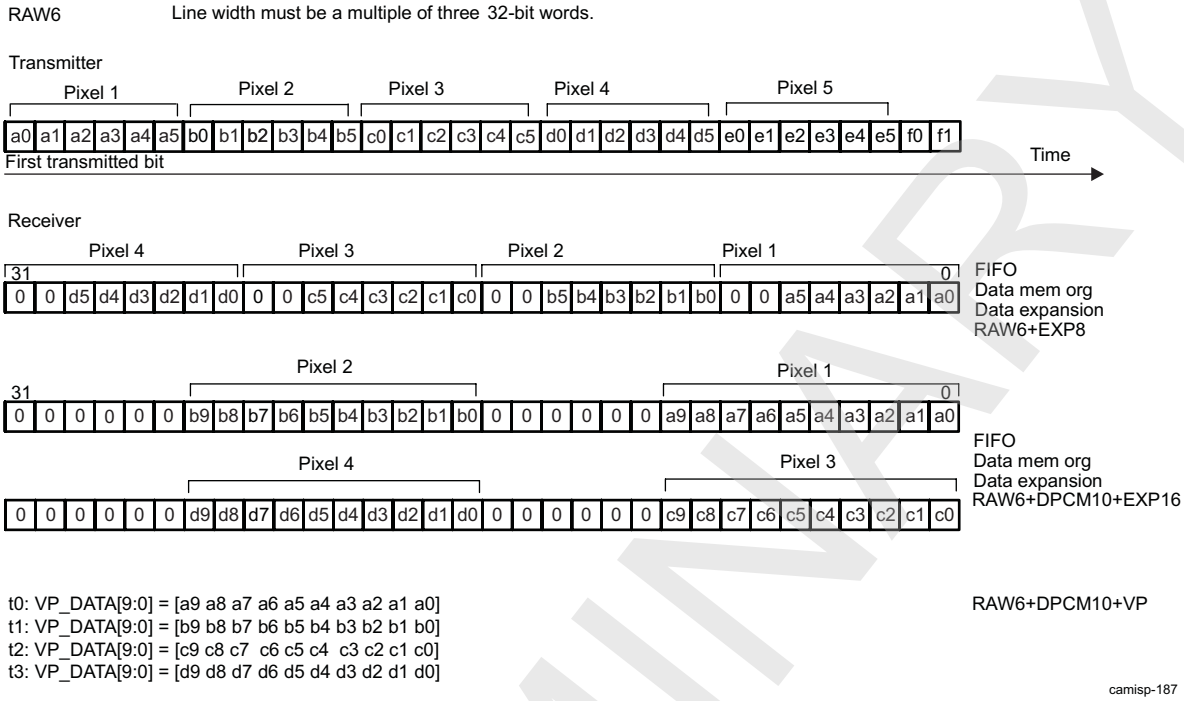
RAW6 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line is a multiple of 3 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 6 is 96; that is 3 x 32 bits).

Figure 6-14 shows RAW6 format.

NOTE: The RAW6 data format do not apply to the MIPI® CSI1 compatible mode.

Figure 6-14. Camera ISP CSI1/CCP2 RAW 6



6.2.4.4.1.3.2 Camera ISP CSI1/CCP2 RAW7 (CCP2 Only)

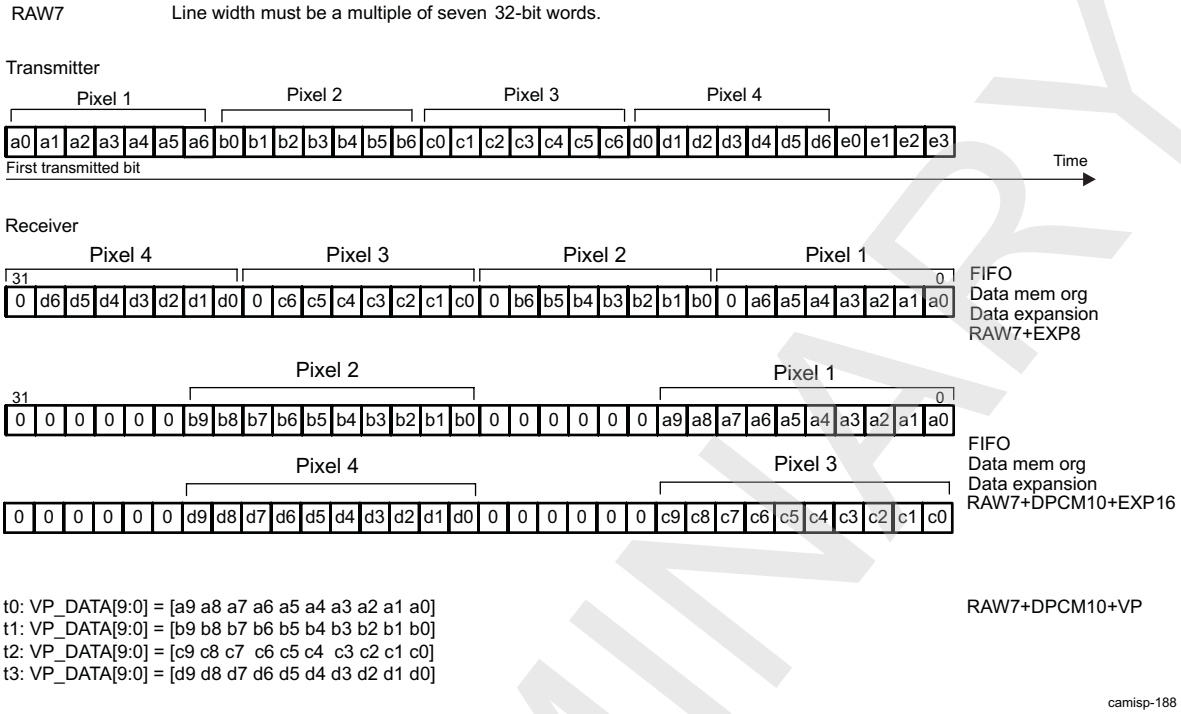
RAW7 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 7 x 32 bits to correctly finish the pixel reconstruction (the lowest common multiple of 32 and 7 is 224; that is, 7 x 32 bits).

Figure 6-15 shows RAW7 format.

NOTE: The RAW7 data format do not apply to the MIPI® CSI1 compatible mode.

Figure 6-15. Camera ISP CSI1/CCP2 RAW 7



6.2.4.4.1.3.3 Camera ISP CSI1/CCP2 RAW8

RAW8 data format can be output to memory in two formats: with no data expansion and with data expansion.

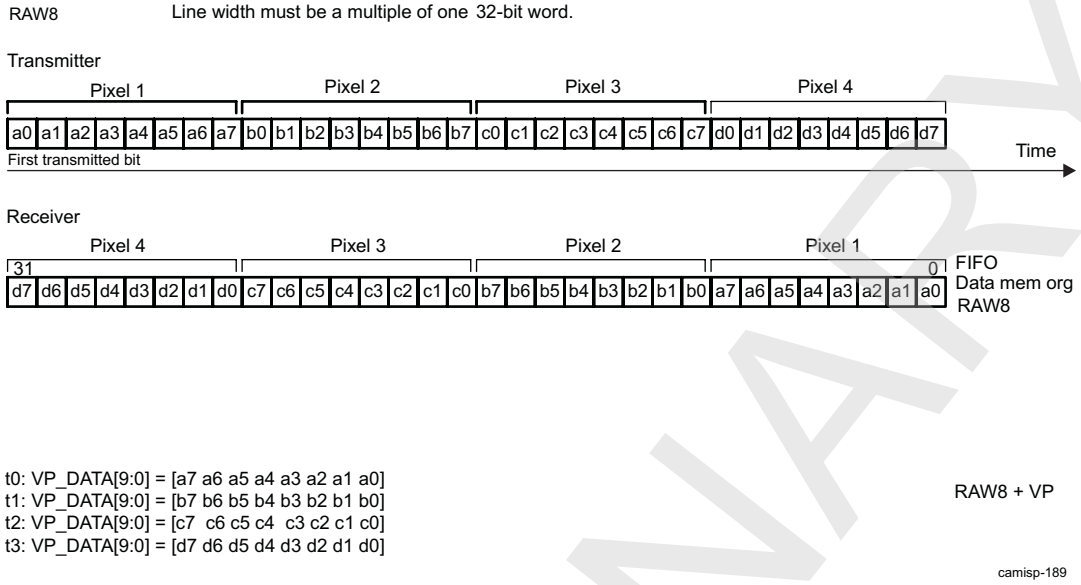
The line length sent through the associated PHY is a multiple of 32 bits.

Figure 6-16 shows RAW8 format.

NOTE:

- Use RAW8 data format to output RAW6 and RAW7 data formats to memory.
- Use YUV422 + VP to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP.

Figure 6-16. Camera ISP CSI1/CCP2 RAW8



6.2.4.4.1.3.4 Camera ISP CSI1/CCP2 RAW10

RAW10 data format can be output to memory in two formats: with no data expansion and with data expansion.

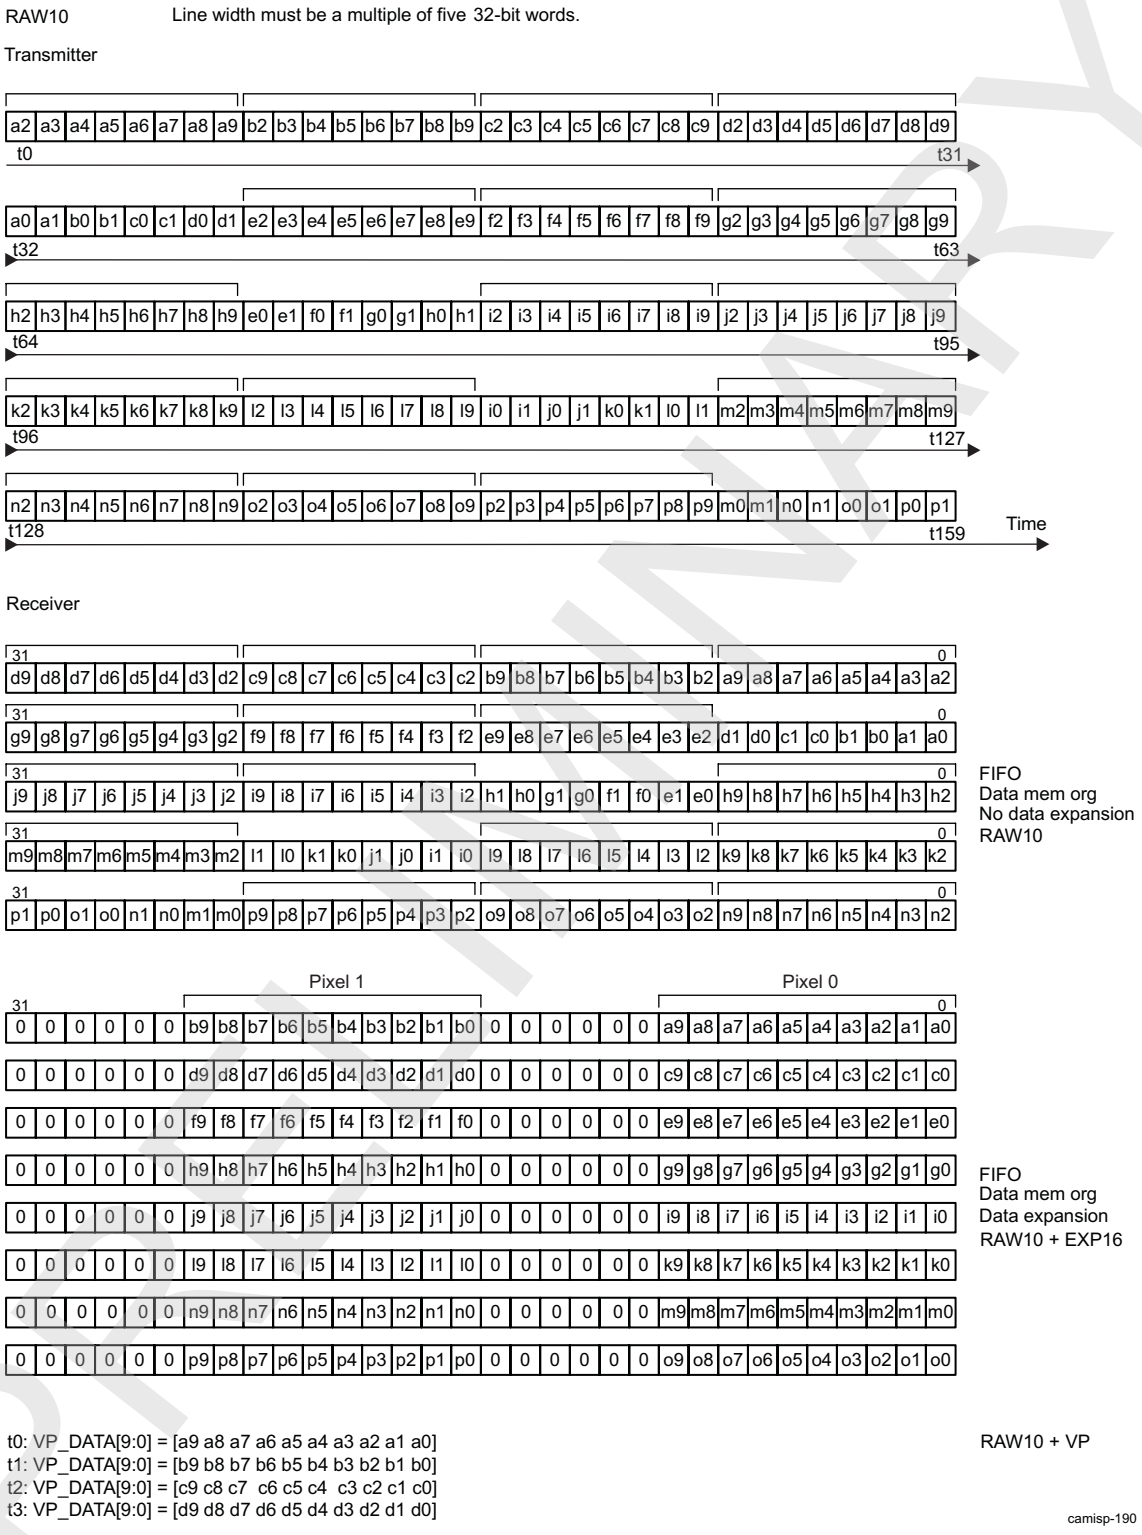
If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 5 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 10 is 320: 10 x 32 bits).

RAW10 data format can be sent to the video port.

Figure 6-17 shows RAW10 format.

Figure 6-17. Camera ISP CSI1/CCP2 RAW10



6.2.4.4.1.3.5 Camera ISP CSI1/CCP2 RAW12

RAW12 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word.

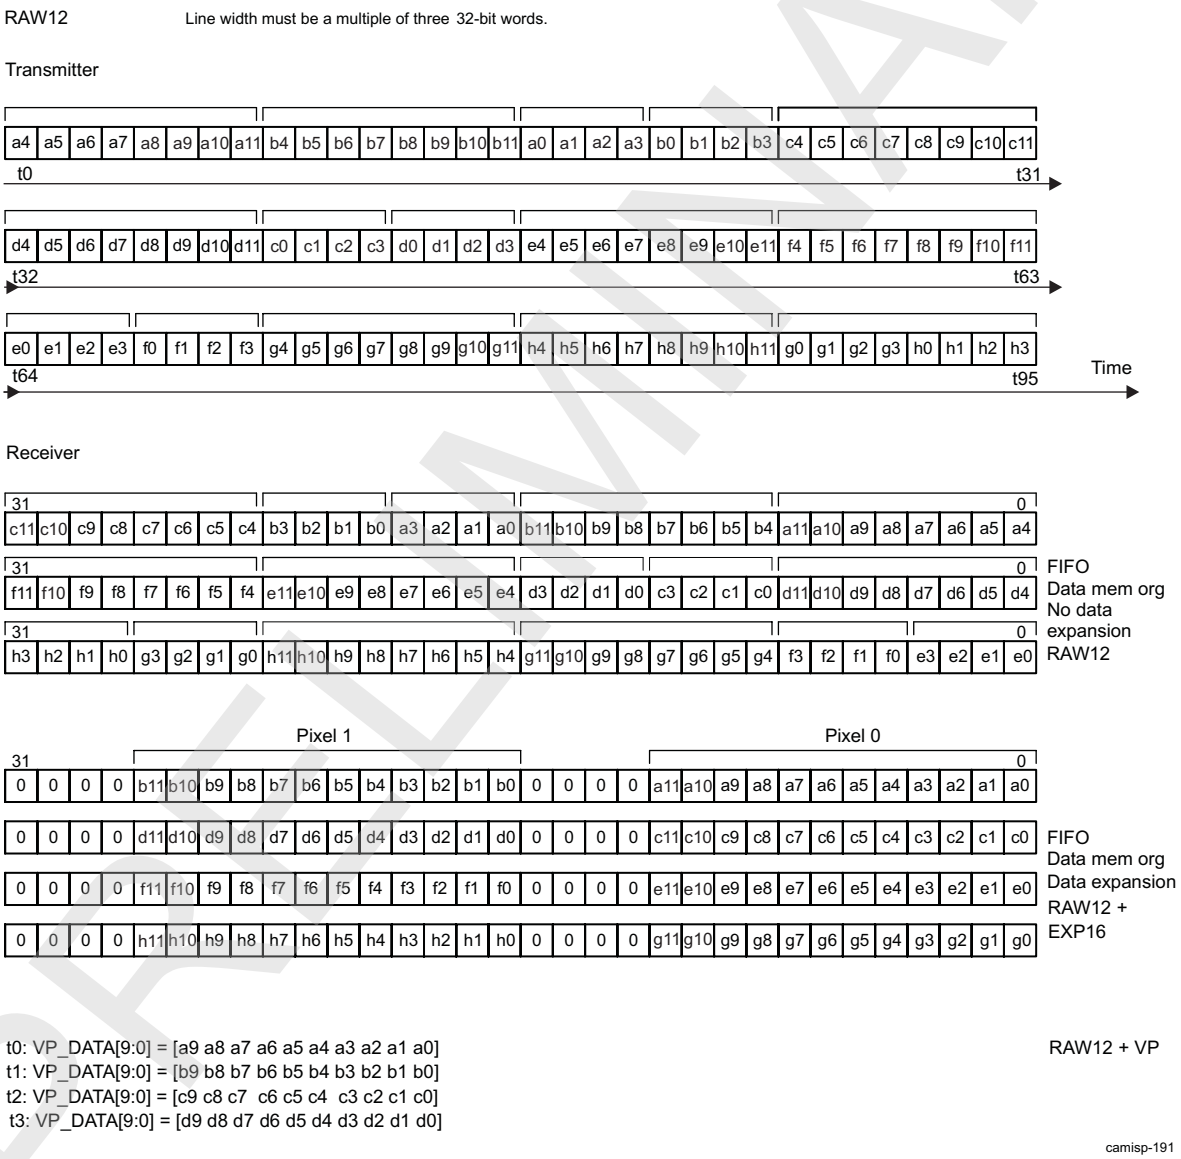
The line length sent through the PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 12 is 96: 3 x 32 bits).

RAW12 data format can be sent to the video port.

Figure 6-18 shows RAW12 format.

NOTE: The Video processing hardware is 10-bit only. Typically, the data lane shifter must be used to perform 10-bit-only processing.

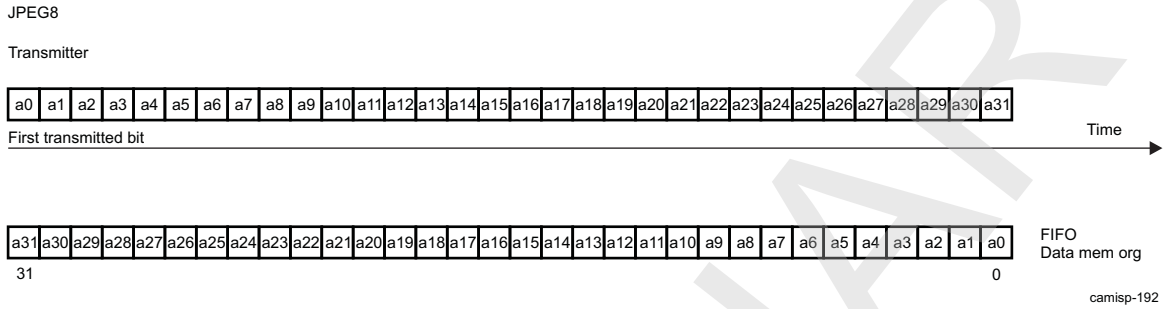
Figure 6-18. Camera ISP CSI1/CCP2 RAW12



6.2.4.4.1.4 Camera ISP CSI1/CCP2 JPEG8 Pixel Data Formats

The line length sent through the associated PHY is a multiple of 32 bits. The false synchronization protection (FSP) code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. Figure 6-19 shows JPEG8 and JPEG8 FSP format.

Figure 6-19. Camera ISP CSI1/CCP2 JPEG8 and JPEG8 FSP



In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream.

In JPEG8 FSP mode, the bitstream is a standard JPEG8 bitstream in which byte-stuffing is used to differentiate synchronization code from original data with the same value. Thus, the JPEG encoder can generate a standard bitstream, and a postprocessing stage (FSP encoder) is used to highlight natural bitstream data equal to synchronization codes, so that the other end can discard the false synchronization codes.

FSP decoding is performed for byte-aligned data and occurs after the frame-start synchronization code is received. If the byte n = 0x0, the FSP decoder looks for bytes 1 and 2. If the bytes are equal to an illegal combination (synchronization codes), the byte 0xA5 that comes after (byte n + 1) is removed from the bitstream.

The 0xA5 padding bytes at the end of the frame are also removed by FSP decoding so that padding does not generate additional data in the FIFO. FSP decoding is then transparent to the software.

Normally, the module detects the illegal combination and then the 0xA5. When the 0xA5 is corrupted or replaced by another code, the value is automatically removed from the bitstream and an interrupt is generated to signal that the code is corrupt and therefore the received data are suspicious. If the line is too noisy for FSP decoding, it is better to configure the subsystem in JPEG8 and use software postprocessing.

6.2.4.5 Camera ISP CSI2 Protocol and Data Format

NOTE: The two CSI2 receivers (CSI2A and CSI2C) support MIPI® CSI2.

6.2.4.5.1 Camera ISP CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2 receiver core depends on the lane configuration.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

The lane merger can merge up to four lanes into a single byte stream.

In case of a single lane, the lane merger is not used to merge byte streams.

Figure 6-20 and Figure 6-21 show an example of byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 6-20. Camera ISP CSI2 Two Data-Lane Merger Configuration

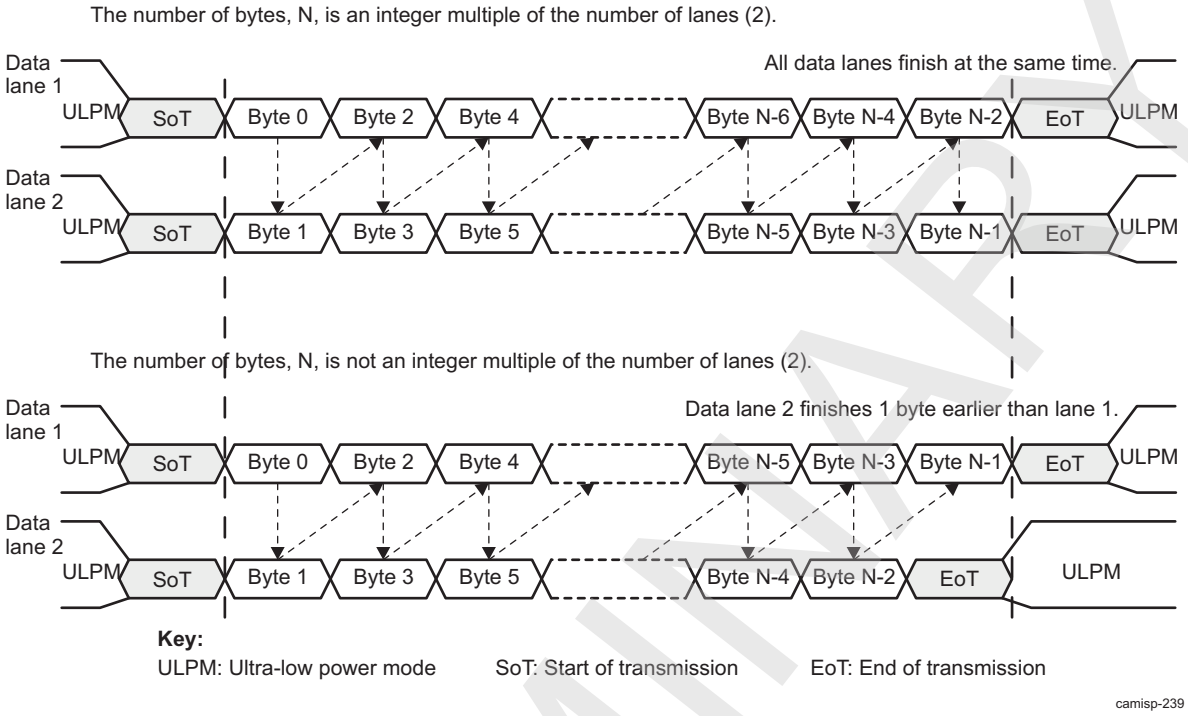


Figure 6-21. Camera ISP CSI2 One Data-Lane Configuration

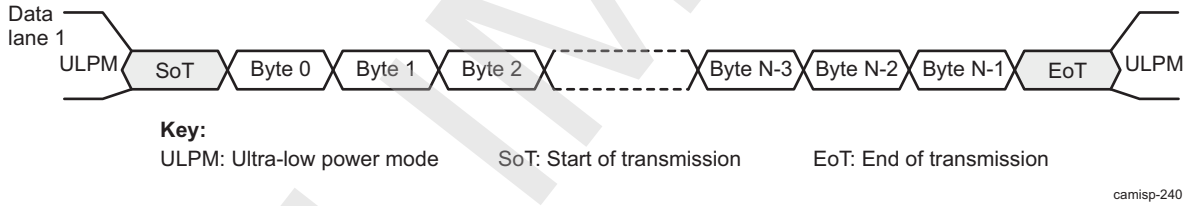


6.2.4.5.2 Camera ISP CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

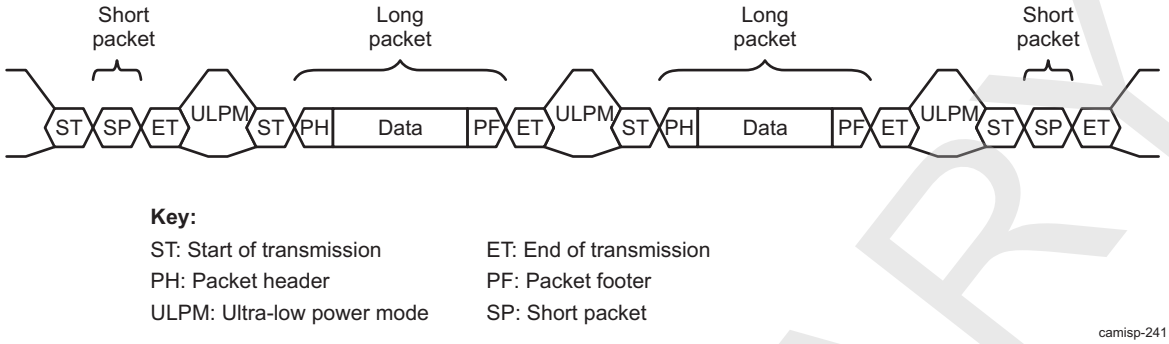
The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 6-22 shows the CSI2 protocol layer with short and long packets.

Figure 6-22. Camera ISP CSI2 Protocol Layer With Short and Long Packets

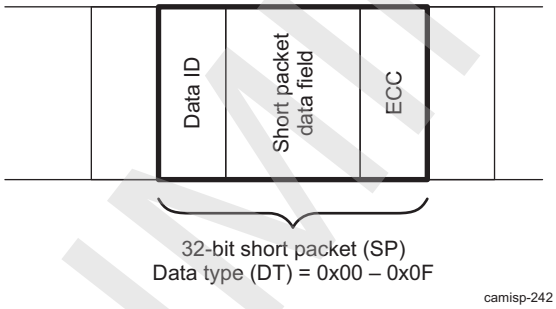


Two packets are always separated from each other with a sequence of a ULPM, an ET, and an ST.

6.2.4.5.2.1 Camera ISP CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 6-23 shows the structure of a short packet.

Figure 6-23. Camera ISP CSI2 Short Packet Structure



For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0. The frame number is inoperative.
- The frame number increments by 1 for every FS packet with the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For line-start code (LSC) and line-end code (LEC) synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0. The line number is inoperative.
- The line number increments by one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended usage is for progressive scan (non-interlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be

different between successive frames. The intended usage is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (there are up to eight contexts to support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

6.2.4.5.2.2 Camera ISP CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements: a 32-bit packet header (PH), an application-specific data payload with a variable number of 8-bit data words, and a 16-bit packet footer (PF). The packet header is further composed of three elements: an 8-bit data identifier, a 16-bit word count field, and an 8-bit ECC. The packet footer has one element, a 16-bit checksum. Figure 6-24 and Table 6-9 show the structure of a long packet.

Figure 6-24. Camera ISP CSI2 Long Packet Structure

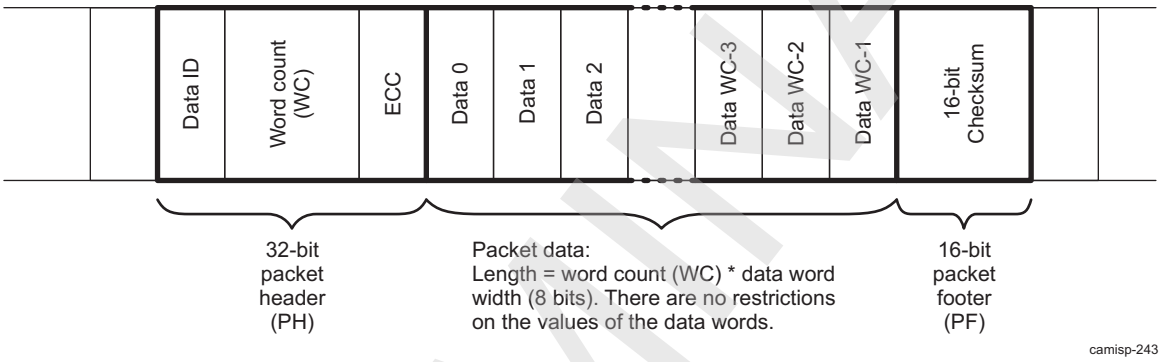


Table 6-9. Camera ISP CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bit)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC * 8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit cyclic redundancy check (CRC) for packet data

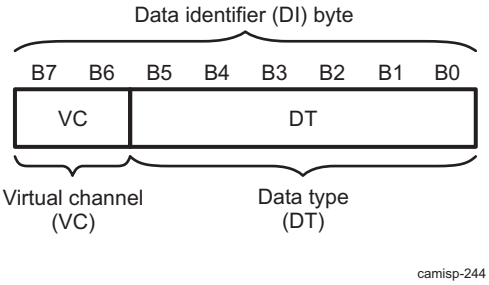
There are no restrictions on packet data size, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

6.2.4.5.2.3 Camera ISP CSI2 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in Figure 6-25. The VC is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 6-25 shows the data identifier structure.

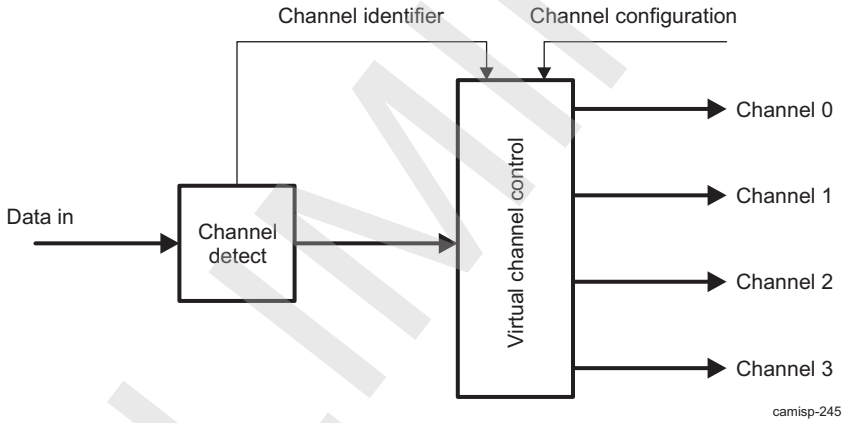
Figure 6-25. Camera ISP CSI2 Data Identifier Structure



Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built up of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. The following synchronization codes are optional for the transmitter: line start and line end. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 6-26 shows a virtual channel.

Figure 6-26. Camera ISP CSI2 Virtual Channel



Pixel Formats

Image-sensor data can have multiple data types. Table 6-10 summarizes the pixel formats supported by the CSI2 receiver interface.

Table 6-10. Camera ISP CSI2 Pixel Format Modes

Mode	Description
YUV420 8-bit	YUV4:2:0 image data

For more information on how the data formats are transmitted and how the data are stored in memory, see Section 6.2.4.5.3, *Camera ISP CSI2 Pixel Data Format*.

6.2.4.5.2.4 Camera ISP CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bit-stream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the current frame

Table 6-11 summarizes the synchronization code values.

Table 6-11. Camera ISP CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

6.2.4.5.2.5 Camera ISP CSI2 Generic Short Packet Codes

When the synchronization code value is between 0x8 and 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

6.2.4.5.2.6 Camera ISP CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit non-image data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

6.2.4.5.2.7 Camera ISP CSI2 Frame Structure

Each frame consists of short packets to indicate start of frame and end of frame. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as start-of-frame (SOF) and end-of-frame (EOF) information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame comprises embedded data and image-sensor data. Figure 6-27 shows where the embedded data and image sensor data are in the frame. The following definitions apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats.
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for software use.

Because the data types are different, the CSI2 receiver uses a different context for embedded data and image-sensor data.

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 6-27. Camera ISP CSI2 General Frame Structure (Informative)

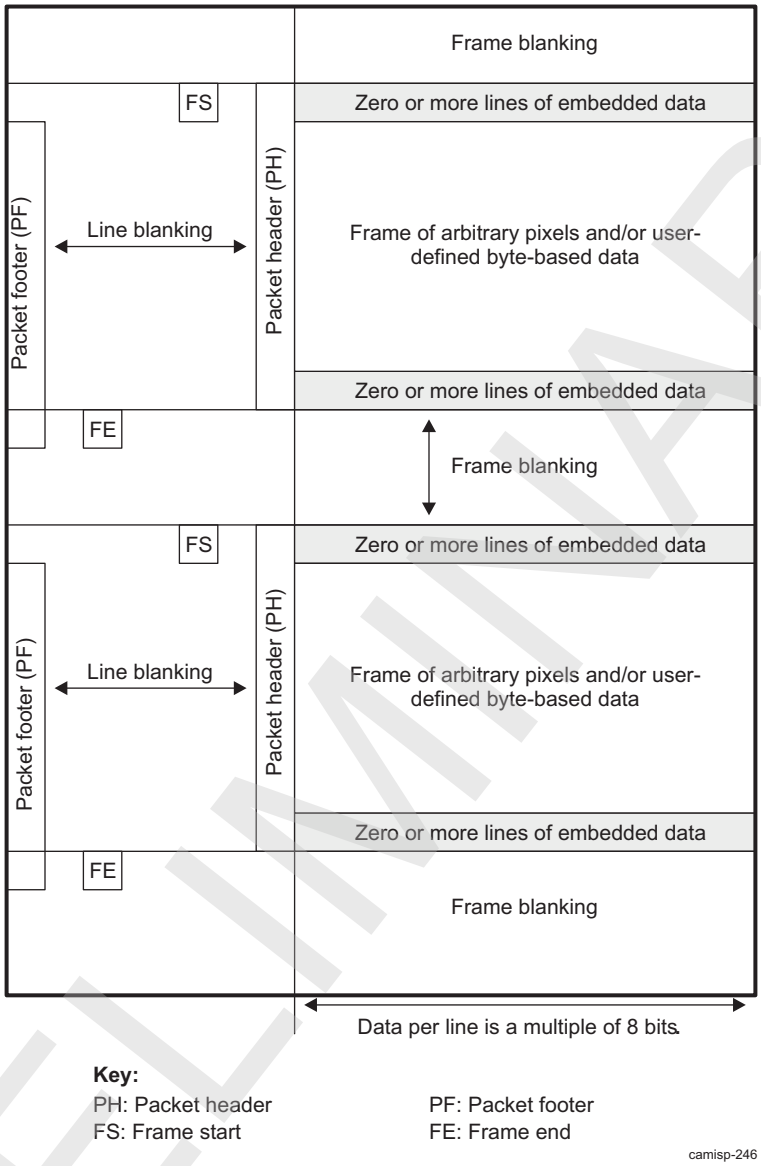

Figure 6-28 shows the frame structure of a YUV422 interlaced video frame without embedded data.

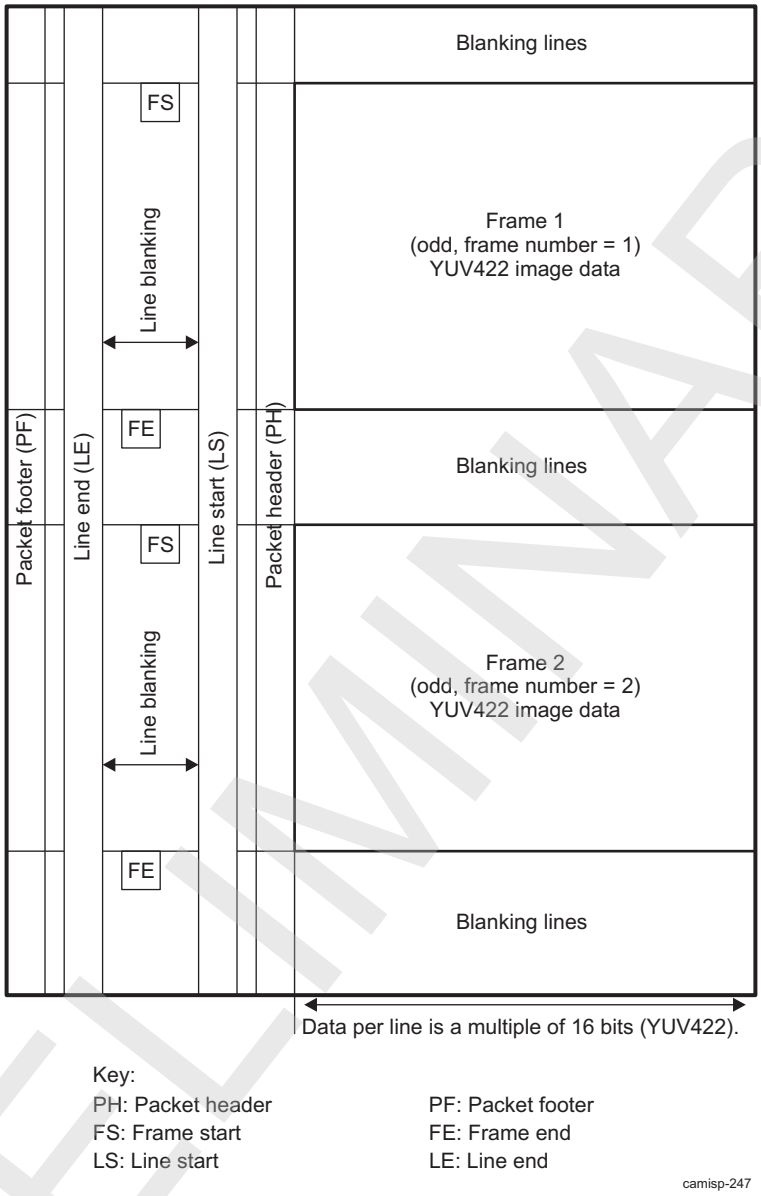
Figure 6-28. Camera ISP CSI2 Digital Interlaced Video Frame (Informative)



The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0.

6.2.4.5.3 Camera ISP CSI2 Pixel Data Format

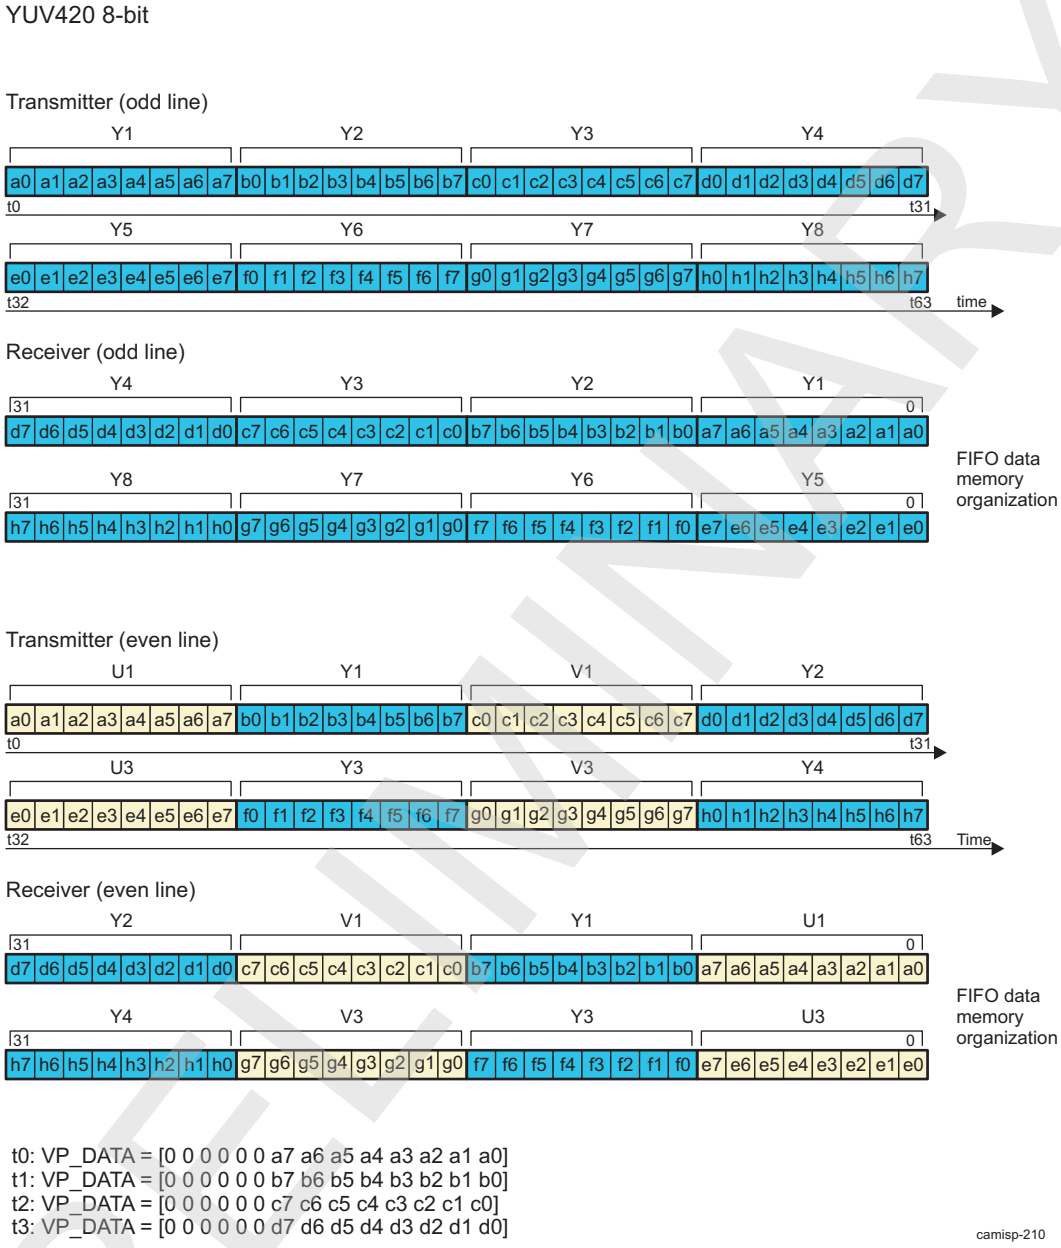
6.2.4.5.3.1 Camera ISP CSI2 YUV Pixel Data Format

6.2.4.5.3.1.1 Camera ISP CSI2 YUV420 8-Bit

YUV420 8-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3*32 bits and the number of lines must be even. Figure 6-29 shows the storage format for YUV420 8-bit data.

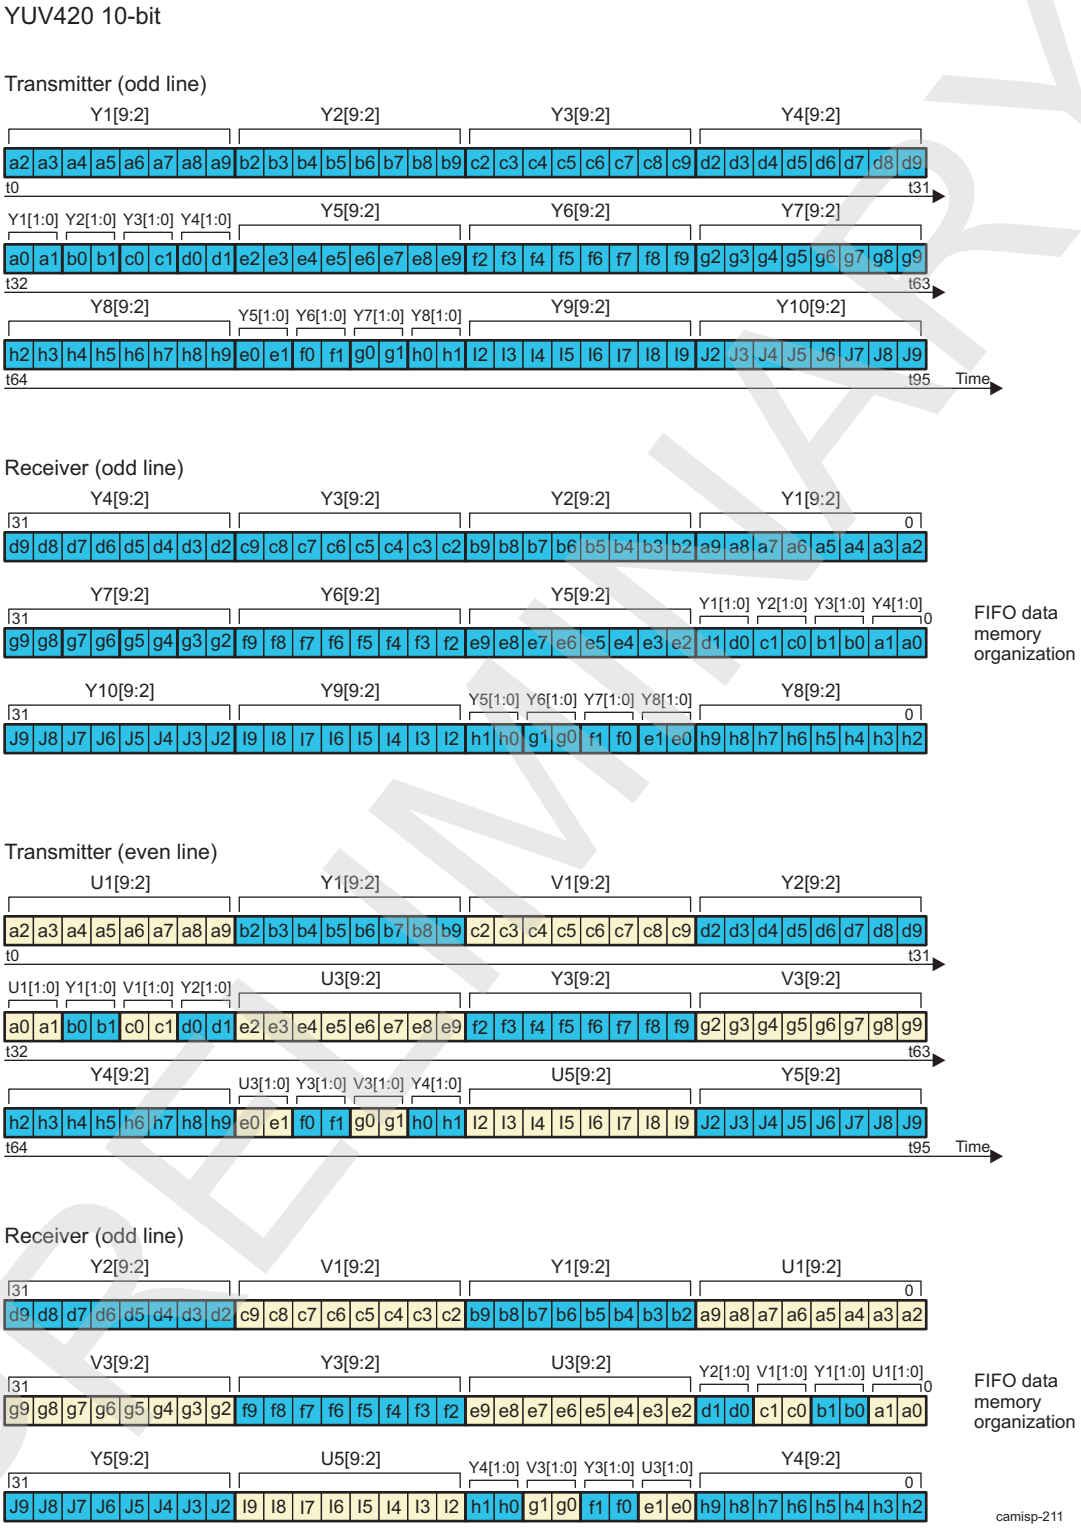
Figure 6-29. Camera ISP CSI2 YUV420 8-Bit



6.2.4.5.3.1.2 Camera ISP CSI2 YUV420 10-Bit

YUV420 10-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. Figure 6-30 shows the storage format for YUV420 10-bit data.

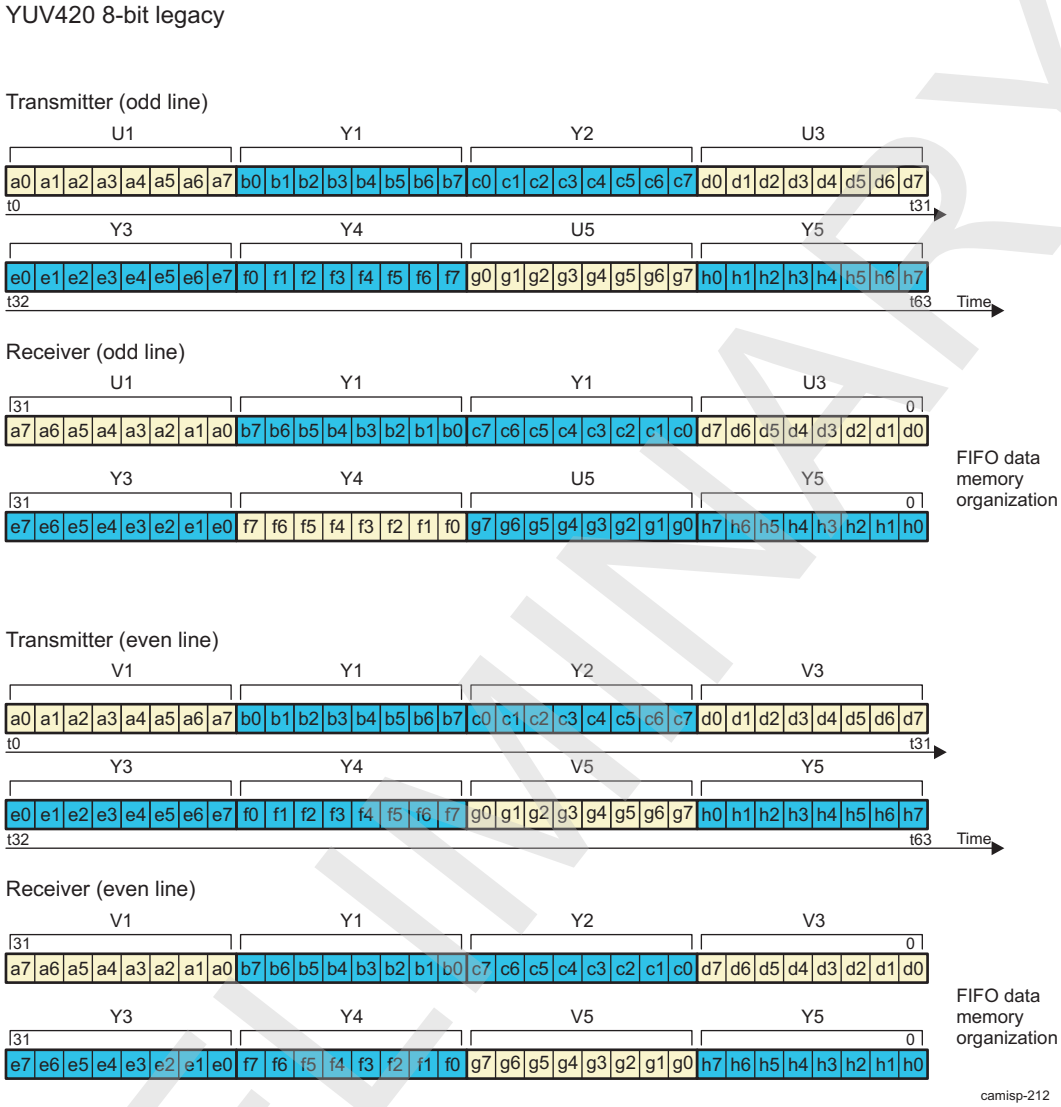
Figure 6-30. Camera ISP CSI2 YUV420 10-Bit



6.2.4.5.3.1.3 Camera ISP CSI2 YUV420 8-Bit Legacy

YUV420 8-bit legacy data can be stored to memory in big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 4 bytes. Figure 6-31 shows the storage format for YUV420 8-bit legacy data.

Figure 6-31. Camera ISP CSI2 YUV420 8-Bit Legacy

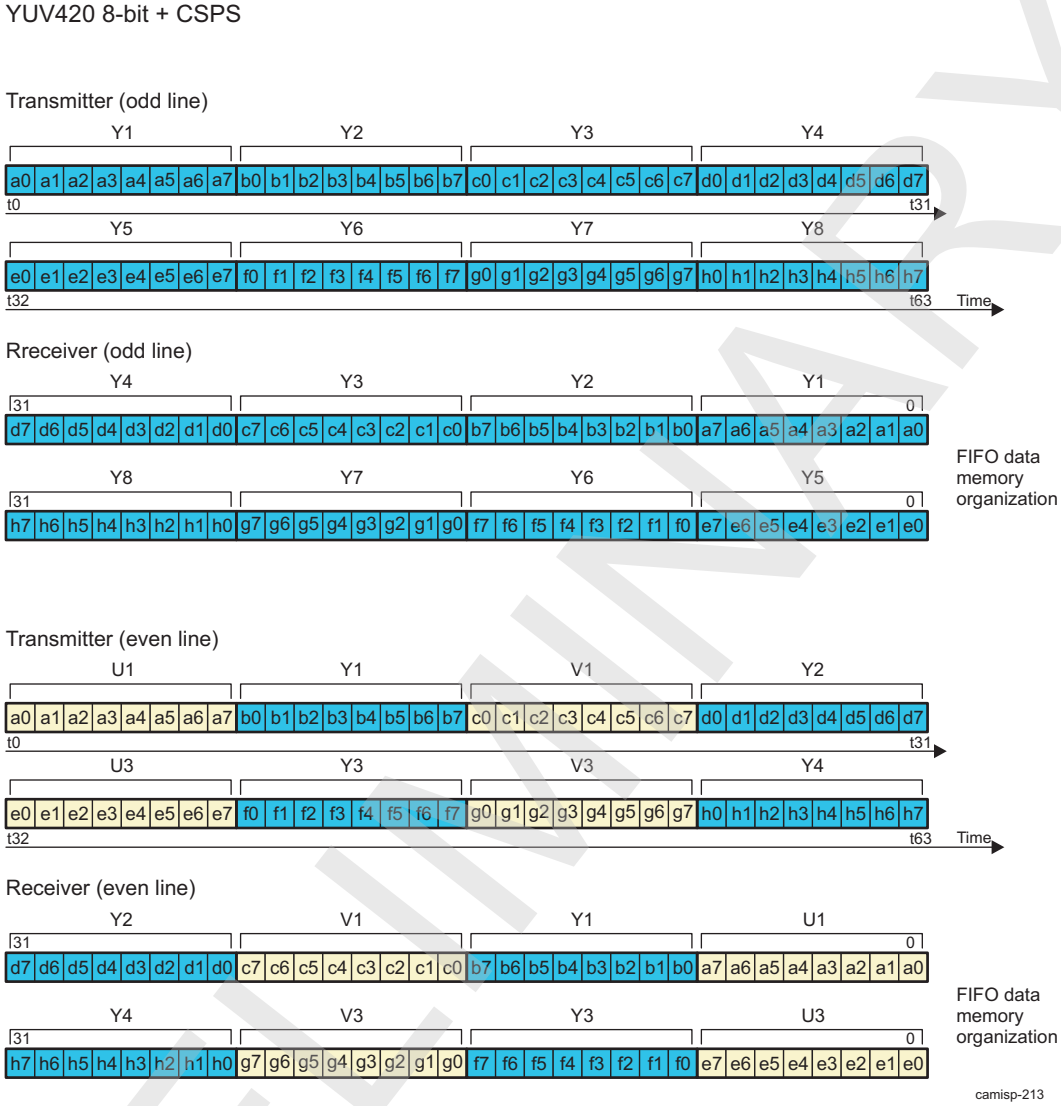


6.2.4.5.3.1.4 Camera ISP CSI2 YUV420 8-Bit + CSPS

YUV420 8-bit CSPS data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3*32 bits and the number of lines must be even. Figure 6-32 shows the storage format for YUV420 8-bit + CSPS data.

Figure 6-32. Camera ISP CSI2 YUV420 8-Bit + CSPS

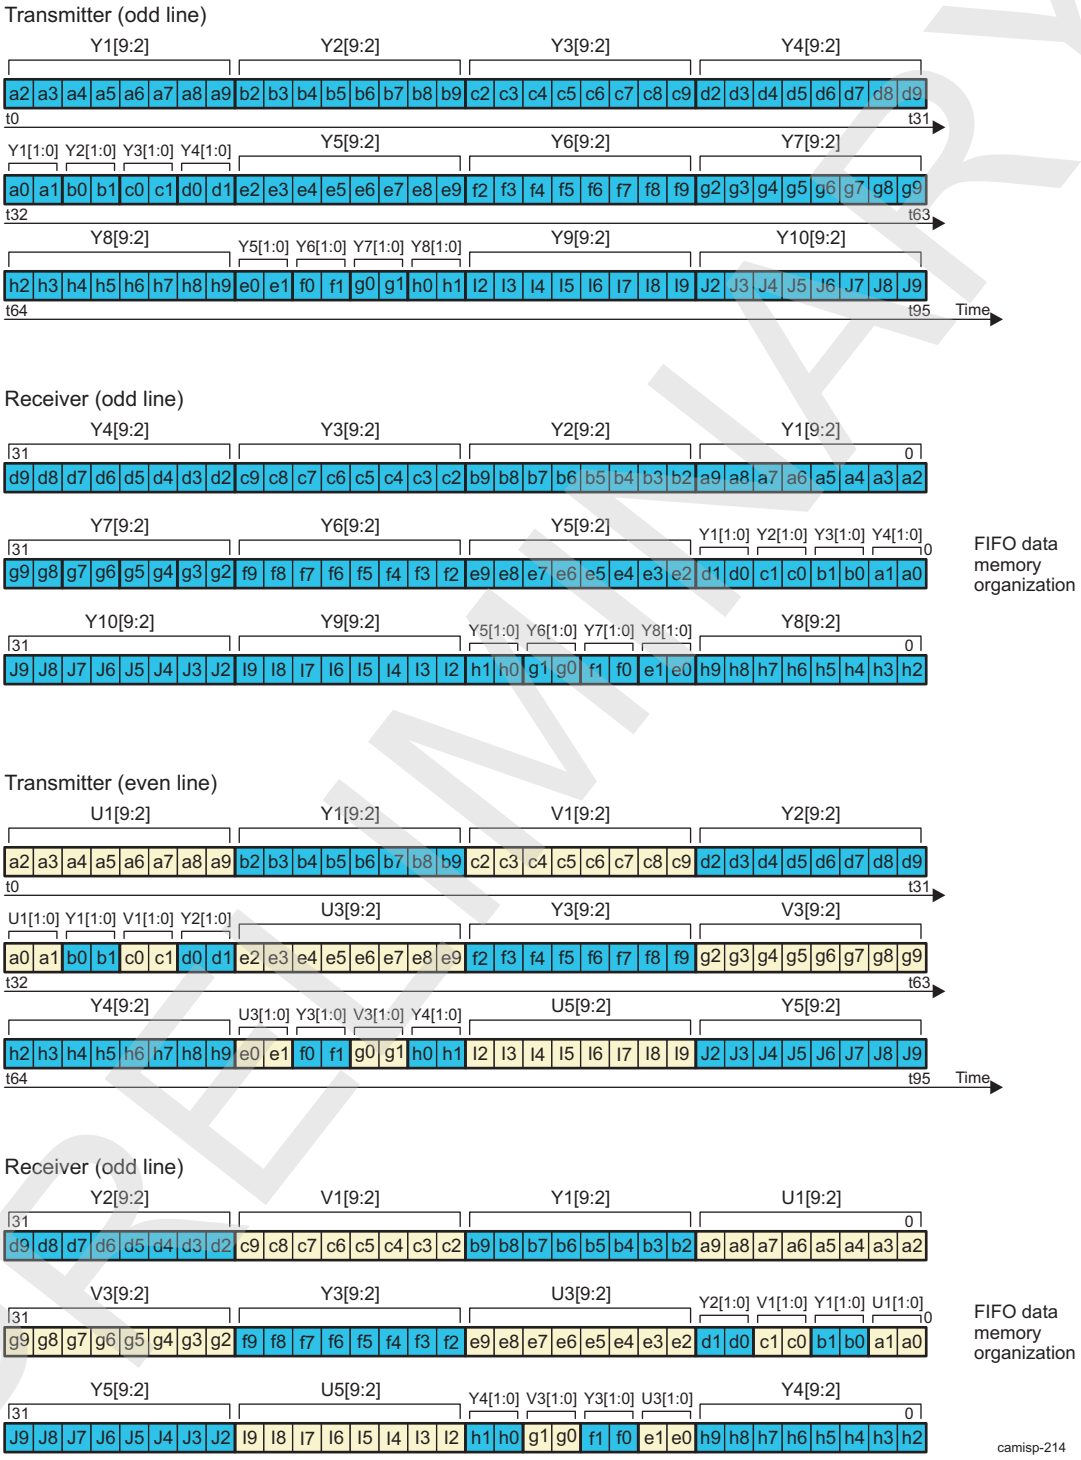


6.2.4.5.3.1.5 Camera ISP CSI2 YUV420 10-Bit + CSPS

YUV420 10-bit CSPS data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3*32 bits and the number of lines must be even. Figure 6-33 shows the storage format for YUV420 10-bit + CSPS data.

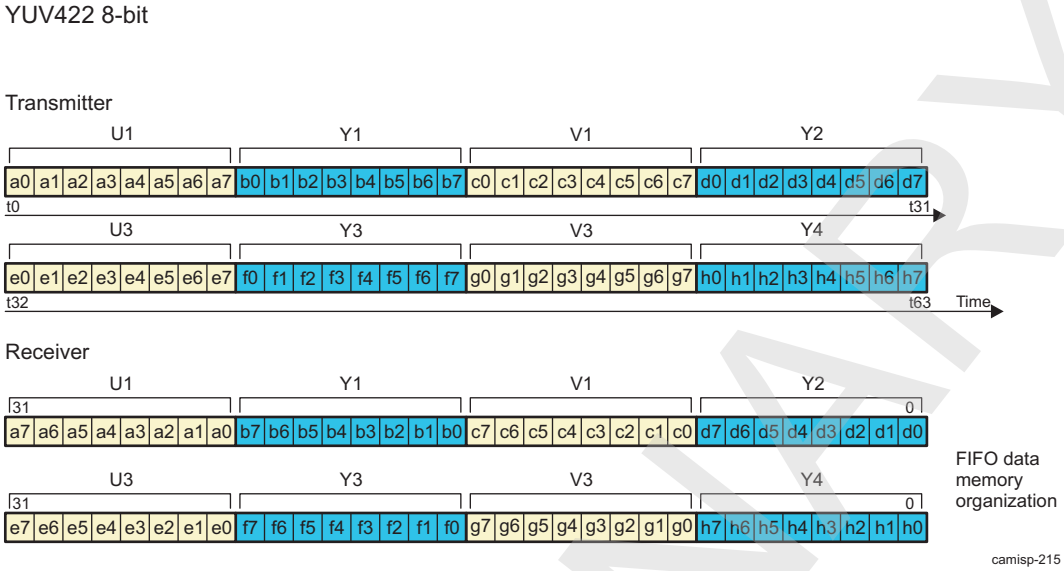
Figure 6-33. Camera ISP CSI2 YUV420 10-Bit + CSPS



6.2.4.5.3.1.6 Camera ISP CSI2 YUV422 8-Bit

YUV422 data can be stored to memory in big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 32 bits. Figure 6-34 shows the storage format for YUV422 8-bit data.

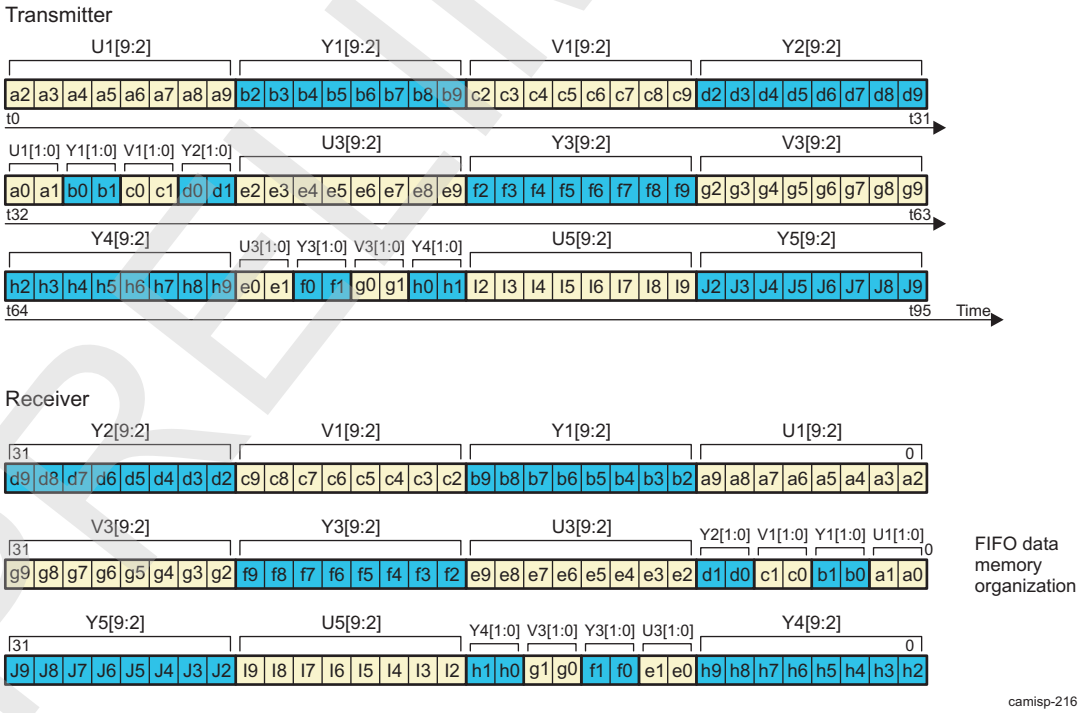
Figure 6-34. Camera ISP CSI2 YUV422 8-Bit



6.2.4.5.3.1.7 Camera ISP CSI2 YUV422 10-Bit

YUV422 data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits. Figure 6-35 shows the storage format for YUV422 10-bit data.

Figure 6-35. Camera ISP CSI2 YUV422 10-Bit

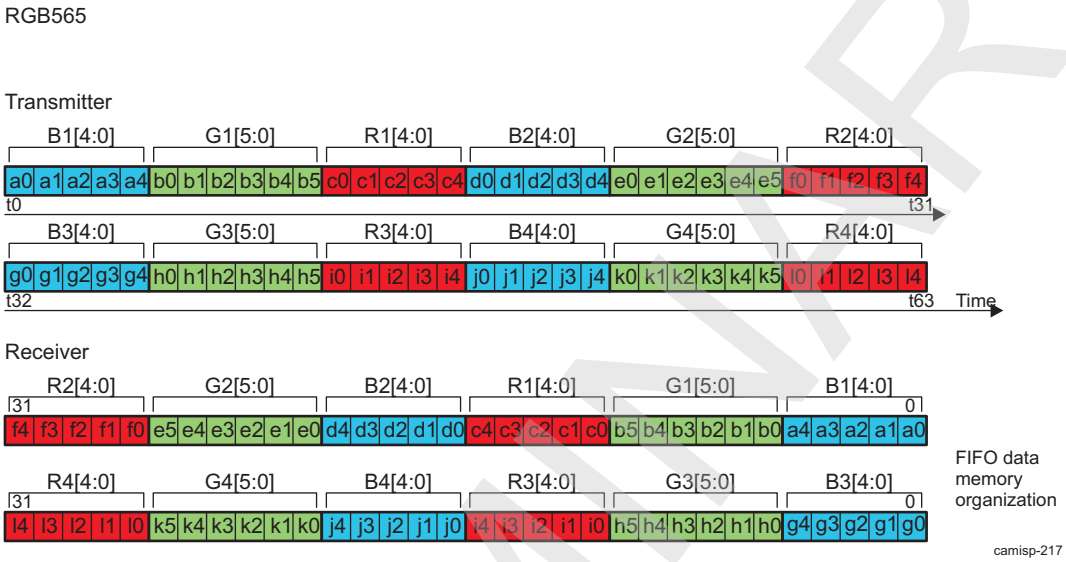


6.2.4.5.3.2 Camera ISP CSI2 RGB Operating Modes

6.2.4.5.3.2.1 Camera ISP CSI2 RGB565

RGB565 data is output to memory without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 16 bits. Figure 6-36 shows the storage format for RGB565 data.

Figure 6-36. Camera ISP CSI2 RGB565

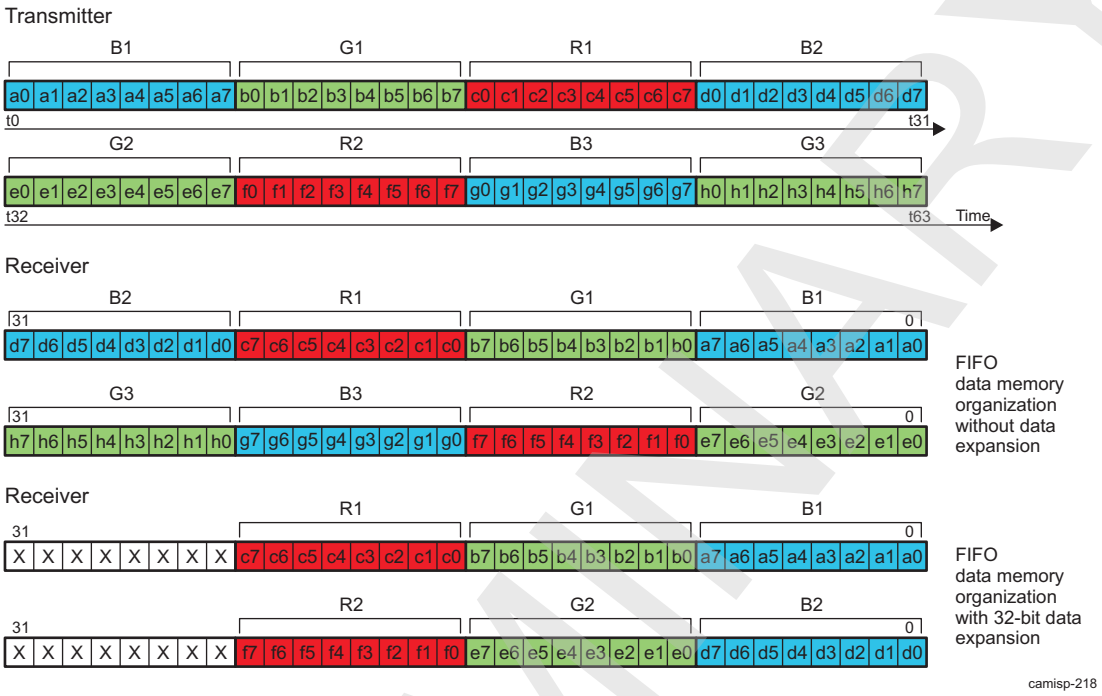


6.2.4.5.3.2.2 Camera ISP CSI2 RGB888

RGB888 data can be output to memory in two formats: with or without data expansion. If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTx_CTRL3 [29:16] ALPHA bit field). Figure 6-37 shows the storage format for RGB888 data.

Figure 6-37. Camera ISP CSI2 RGB888

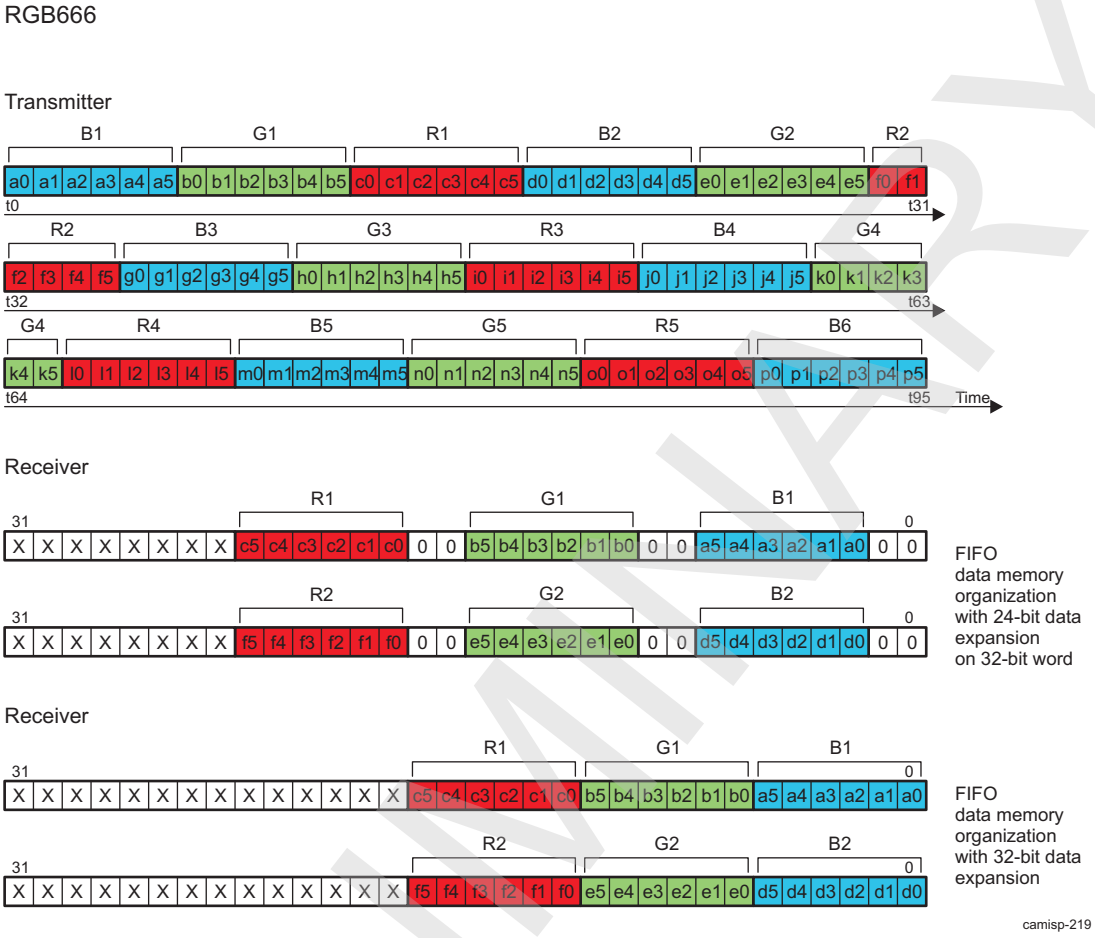
RGB888



6.2.4.5.3.2.3 Camera ISP CSI2 RGB666

RGB666 data is always output to memory with data expansion. The value of the 14 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTx_CTRL3 [29:16] ALPHA bit field). The line length sent through the CSI2 physical protocol is a multiple of 8 bits. Furthermore, the line length is a multiple of 9x8 bits to correctly finish the pixel reconstruction. Figure 6-38 shows the storage format for RGB666 data.

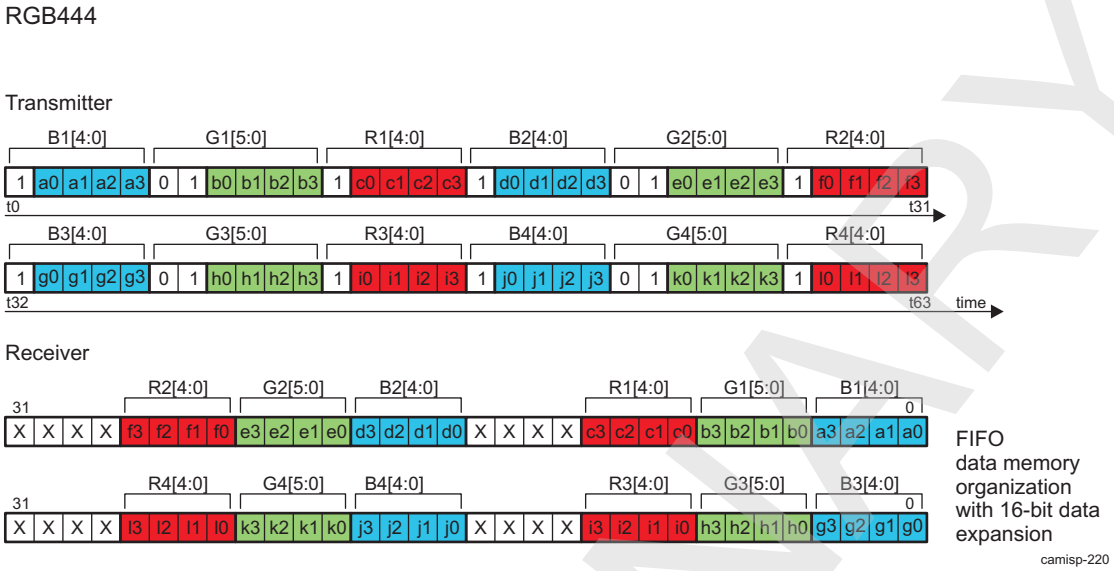
Figure 6-38. Camera ISP CSI2 RGB666



6.2.4.5.3.2.4 Camera ISP CSI2 RGB444

RGB444 data is output to memory with data expansion. When data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications (the CSI2_CTx_CTRL3[29:16] ALPHA bit field). Figure 6-39 shows the storage format for RGB444 data.

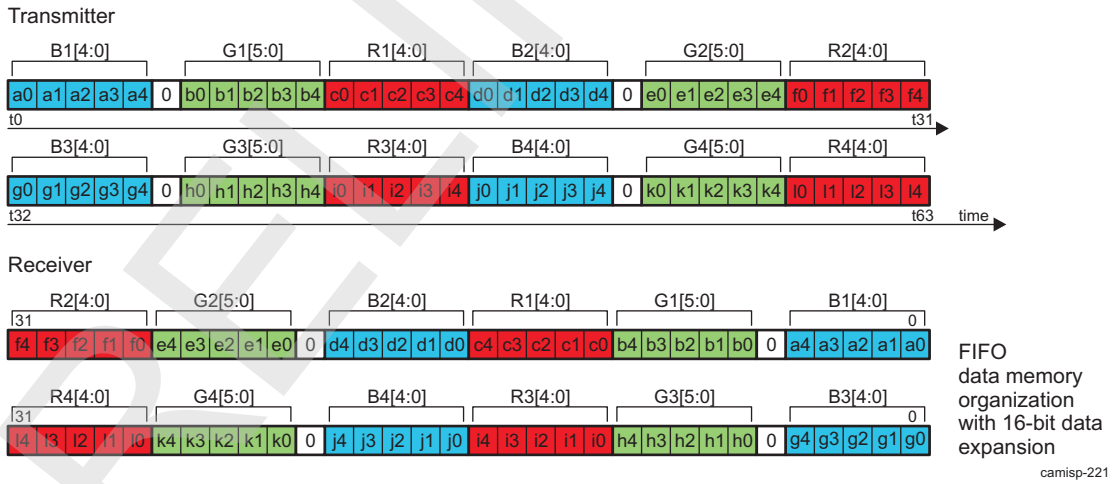
Figure 6-39. Camera ISP CSI2 RGB444



6.2.4.5.3.2.5 Camera ISP CSI2 RGB555

RGB555 data is output to memory with data expansion. Figure 6-40 shows the storage format for RGB555 data.

Figure 6-40. Camera ISP CSI2 RGB555

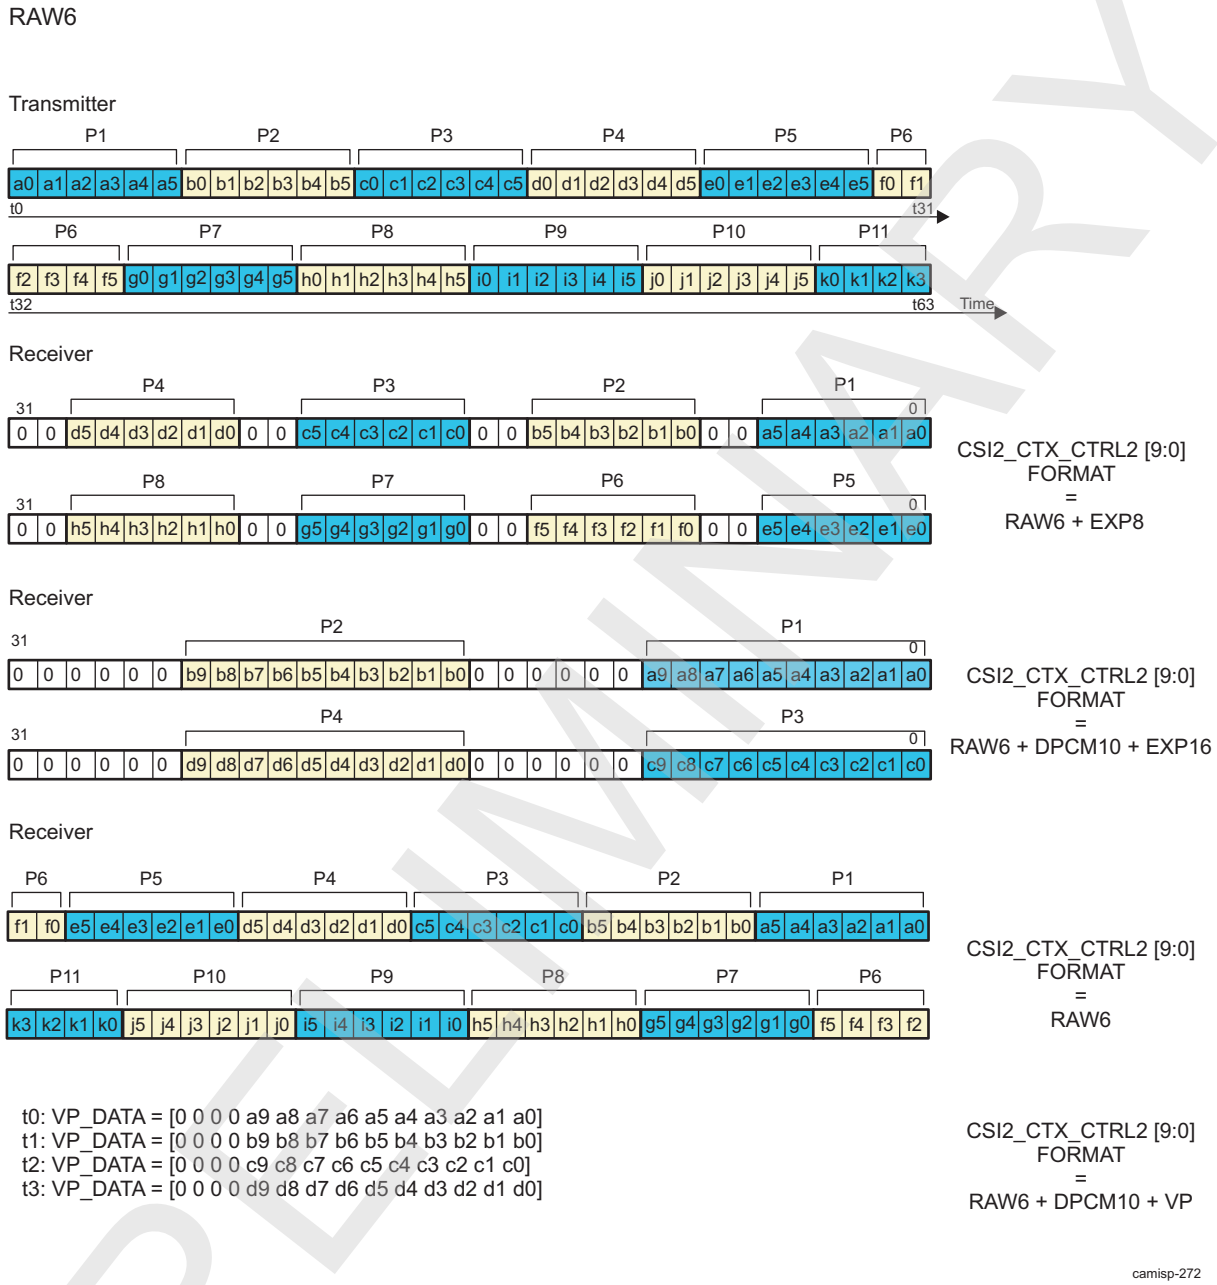


6.2.4.5.3.3 Camera ISP CSI2 RAW Bayer RGB Operating Modes

6.2.4.5.3.3.1 Camera ISP CSI2 RAW6

RAW6 data can be output only with data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 3x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 6 is 24, so 3x8 bits). Figure 6-41 shows the storage format for RAW6 data.

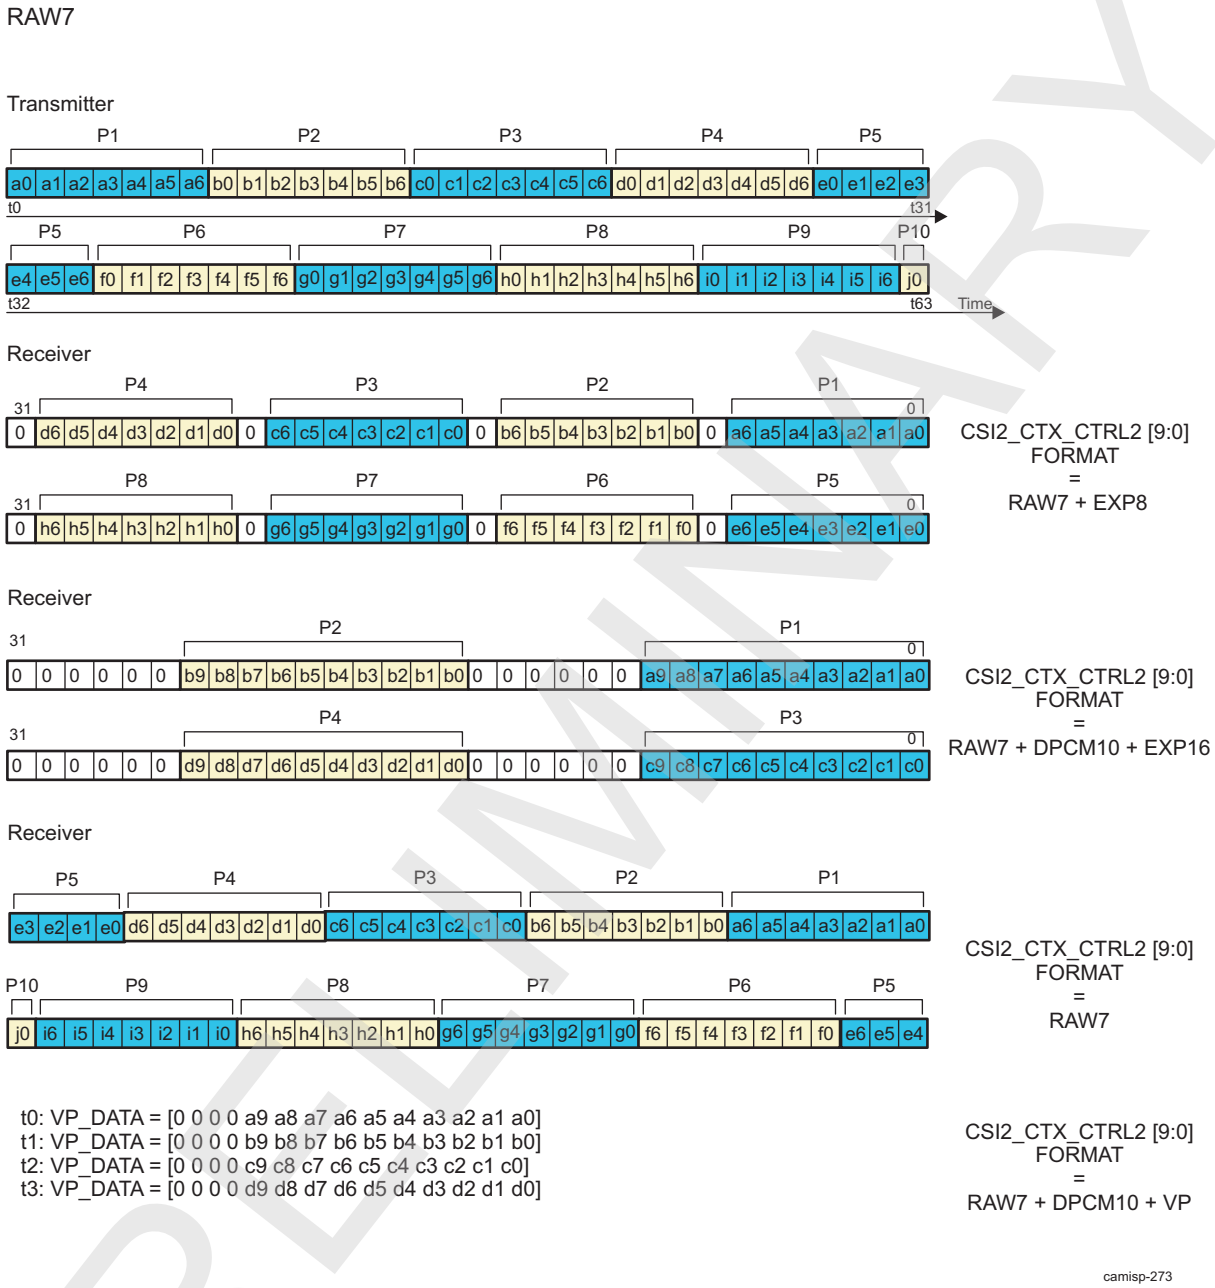
Figure 6-41. Camera ISP CSI2 RAW6



6.2.4.5.3.3.2 Camera ISP CSI2 RAW7

RAW7 data can be output only with data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 7 is 56, so 7x8 bits). Figure 6-42 shows the storage format for RAW7 data.

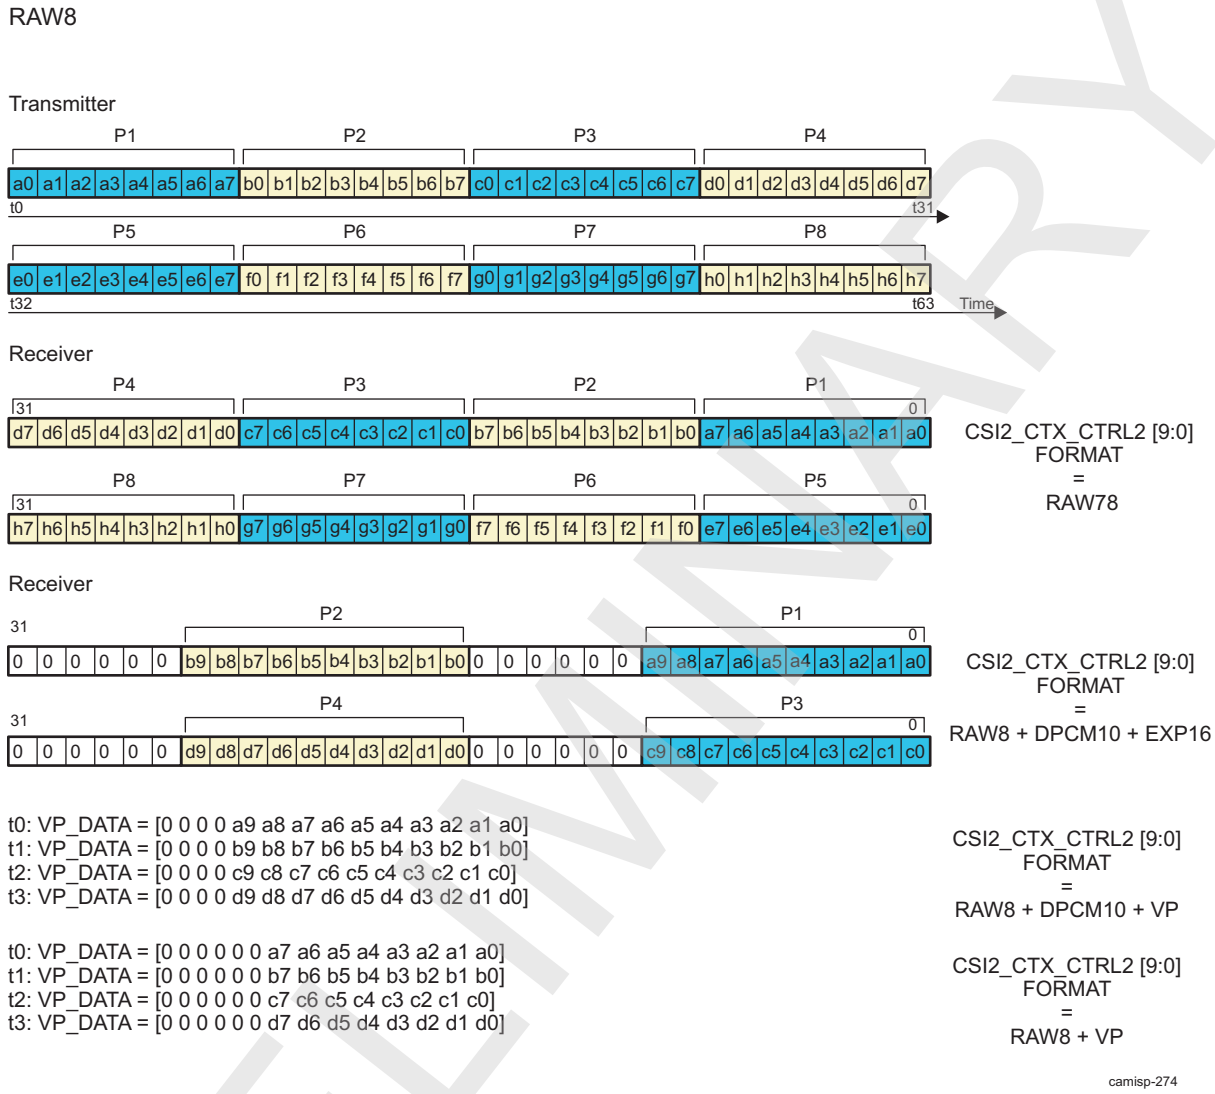
Figure 6-42. Camera ISP CSI2 RAW7



6.2.4.5.3.3.3 Camera ISP CSI2 RAW8

RAW8 data can be output only without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 8 bits. Figure 6-43 shows the storage format for RAW8 data.

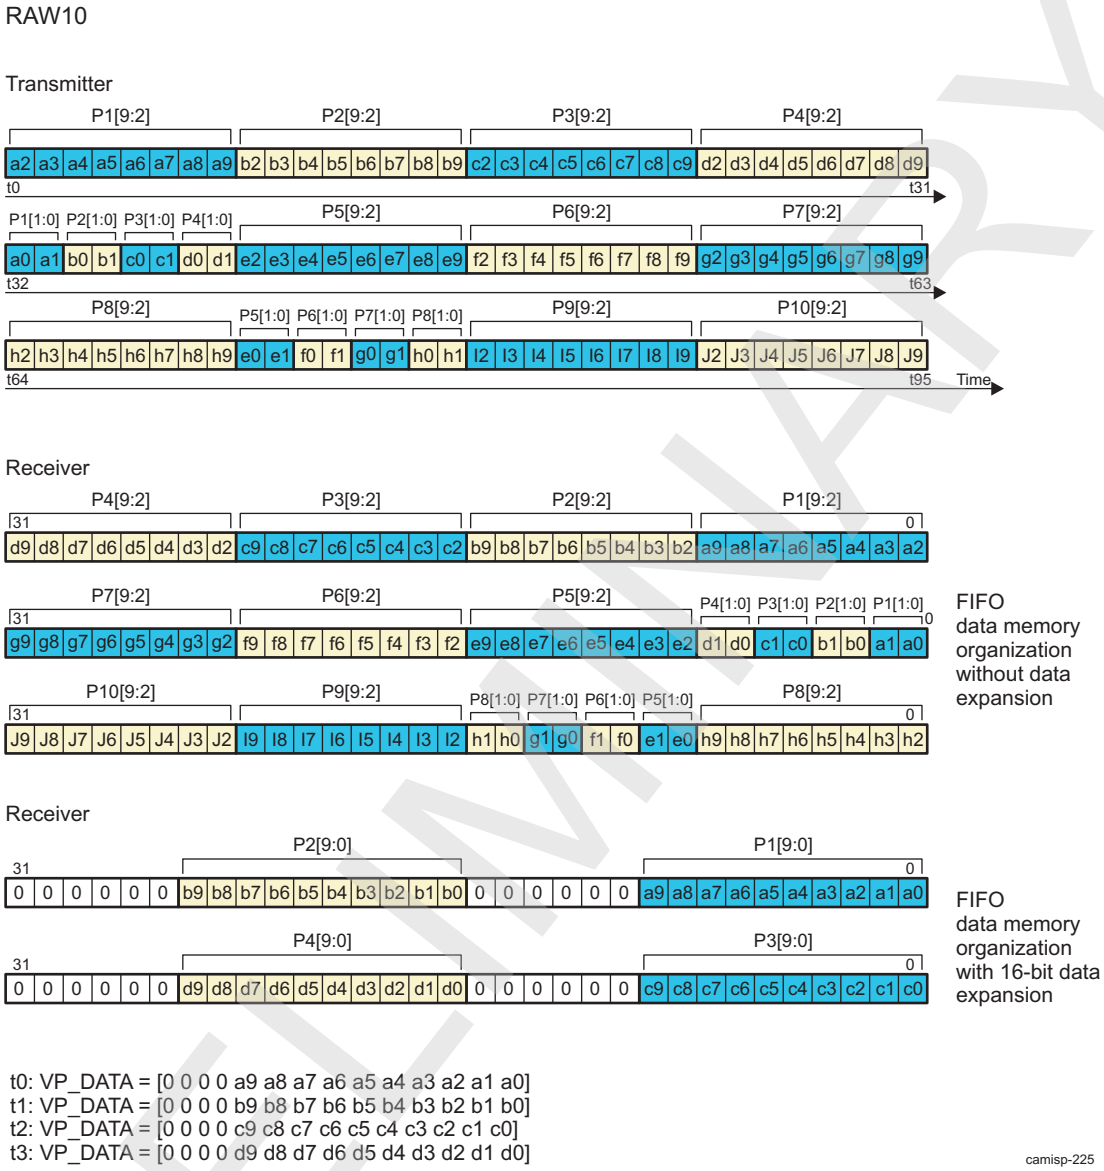
Figure 6-43. Camera ISP CSI2 RAW8



6.2.4.5.3.3.4 Camera ISP CSI2 RAW10

RAW10 data can be output memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 5x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 10 is 40, so 5x8 bits). Figure 6-44 shows the storage format for RAW10 data.

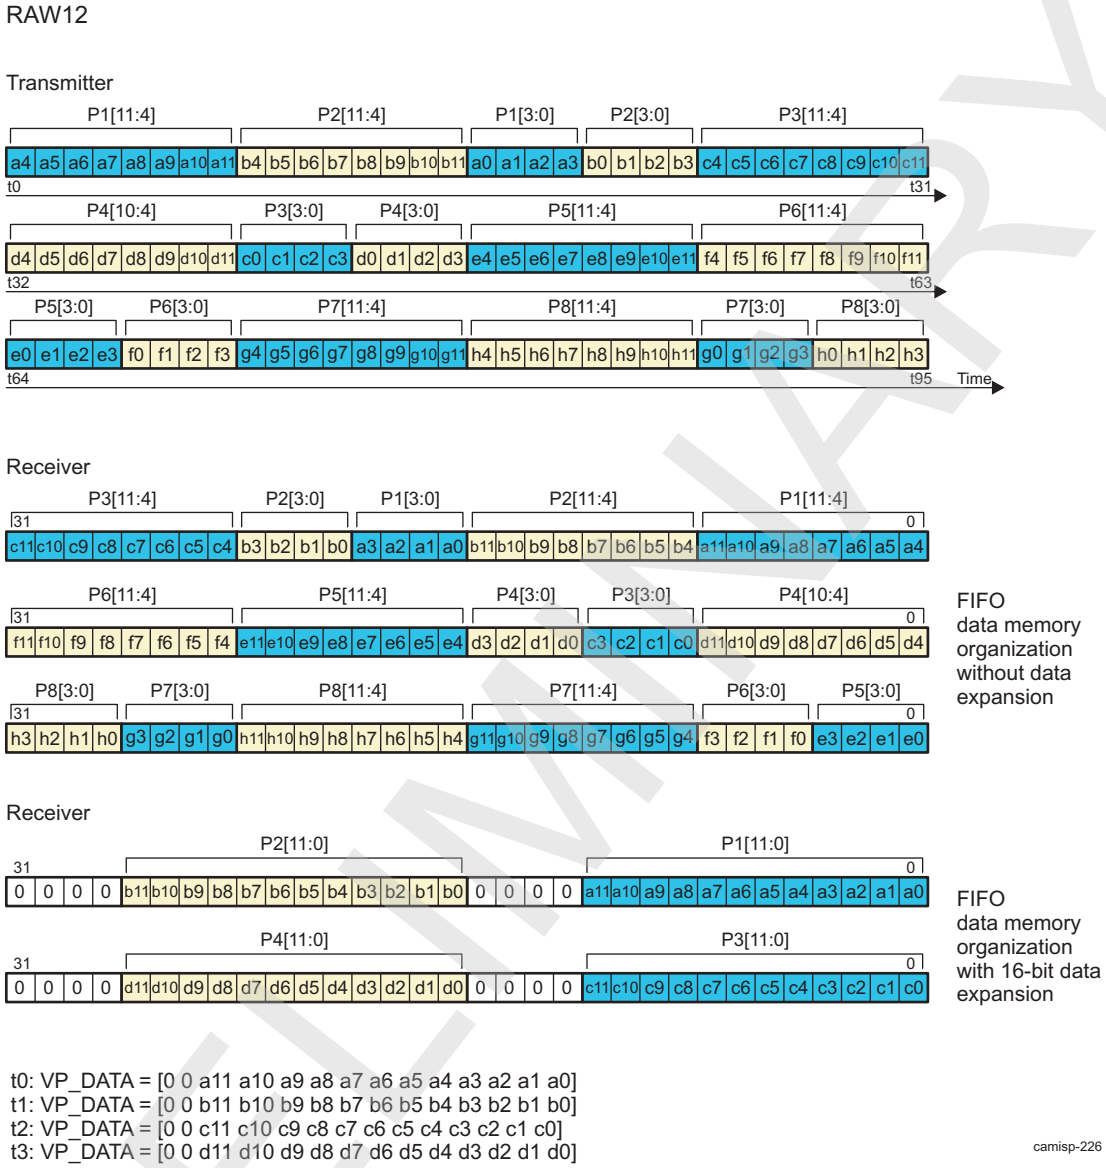
Figure 6-44. Camera ISP CSI2 RAW10



6.2.4.5.3.3.5 Camera ISP CSI2 RAW12

RAW12 data can be output to memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 3x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 12 is 24, so 3x8 bits). Figure 6-45 shows the storage format for RAW12 data.

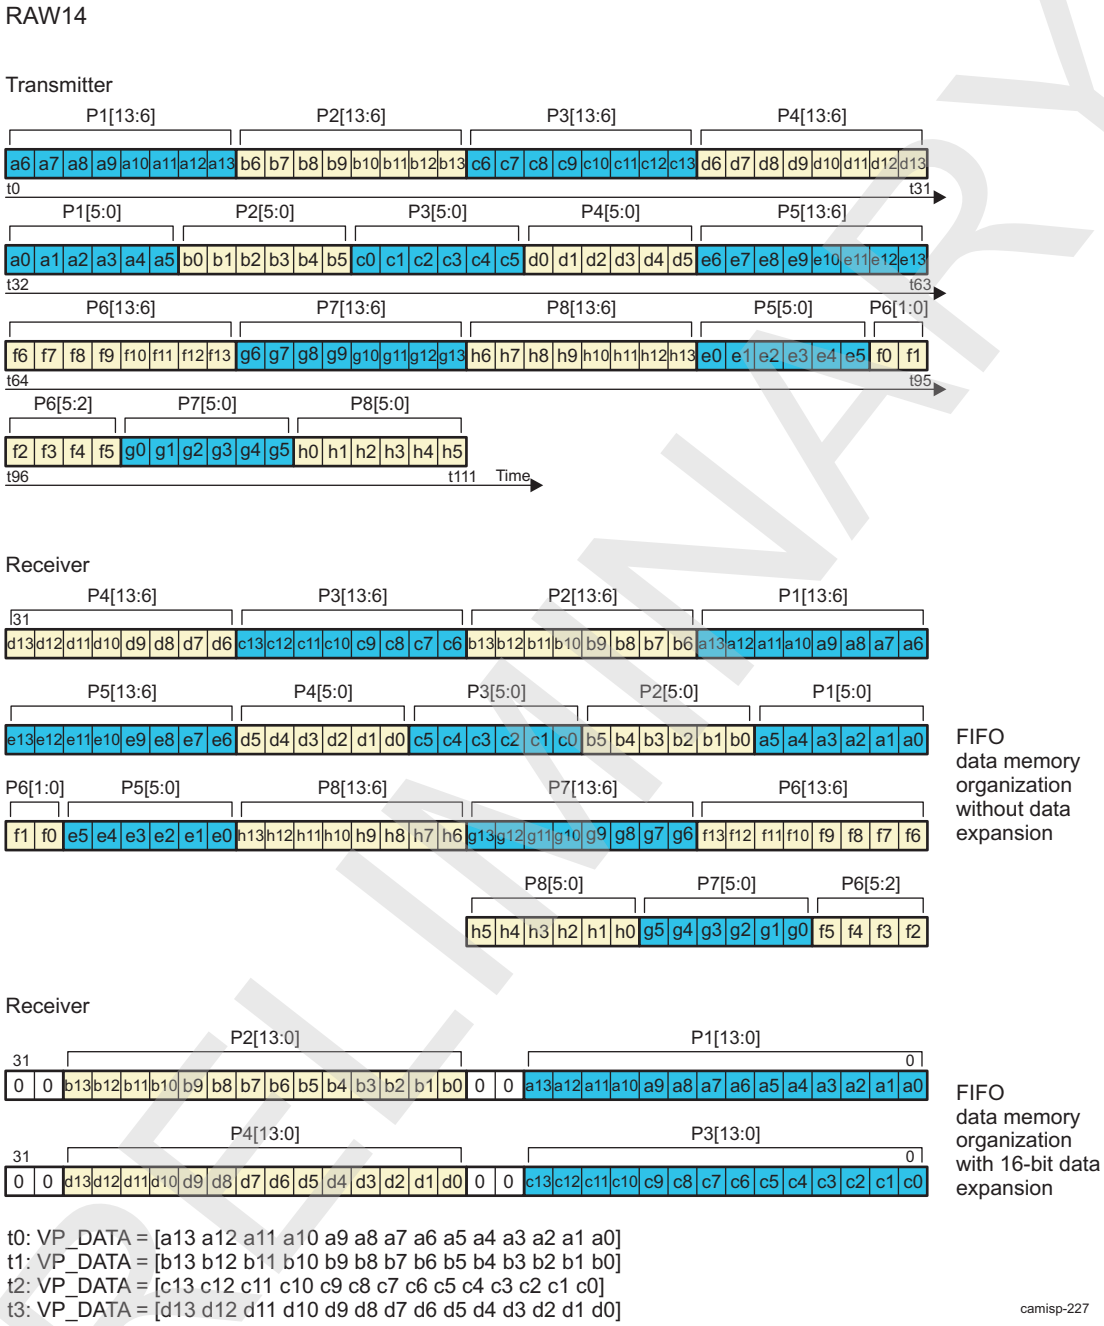
Figure 6-45. Camera ISP CSI2 RAW12



6.2.4.5.3.3.6 Camera ISP CSI2 RAW14

RAW14 data can be output to memory in two formats: with or without data expansion. It can be sent to video port too. If data expansion is used, the 14-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7x8 bits to correctly complete the pixel reconstruction (the lowest common multiple of 8 and 14 is 56, so 7x8 bits). Figure 6-46 shows the storage format for RAW14 data.

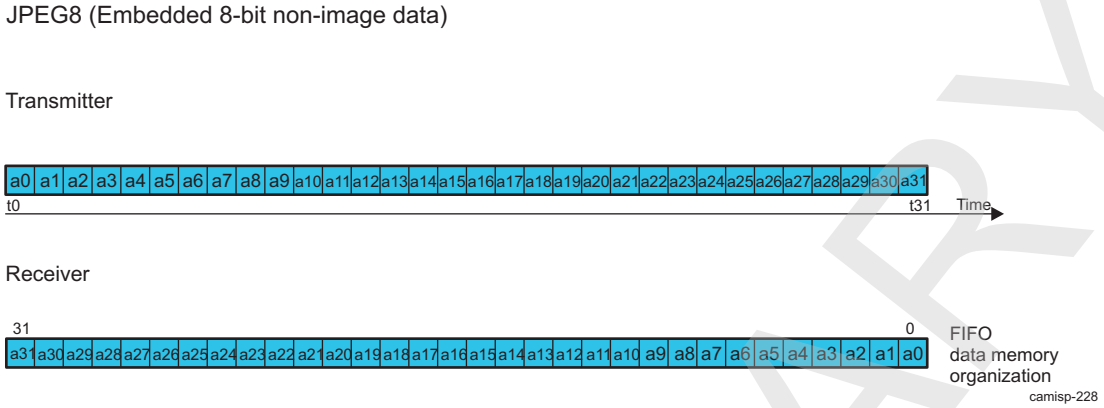
Figure 6-46. Camera ISP CSI2 RAW14



6.2.4.5.3.4 Camera ISP CSI2 JPEG8 Operating Modes

The size of a compressed stream can be known in advance. Figure 6-47 shows the format for storing JPEG8 data.

Figure 6-47. Camera ISP CSI2 JPEG8



6.2.4.5.3.5 Camera ISP CSI2 Generic Format

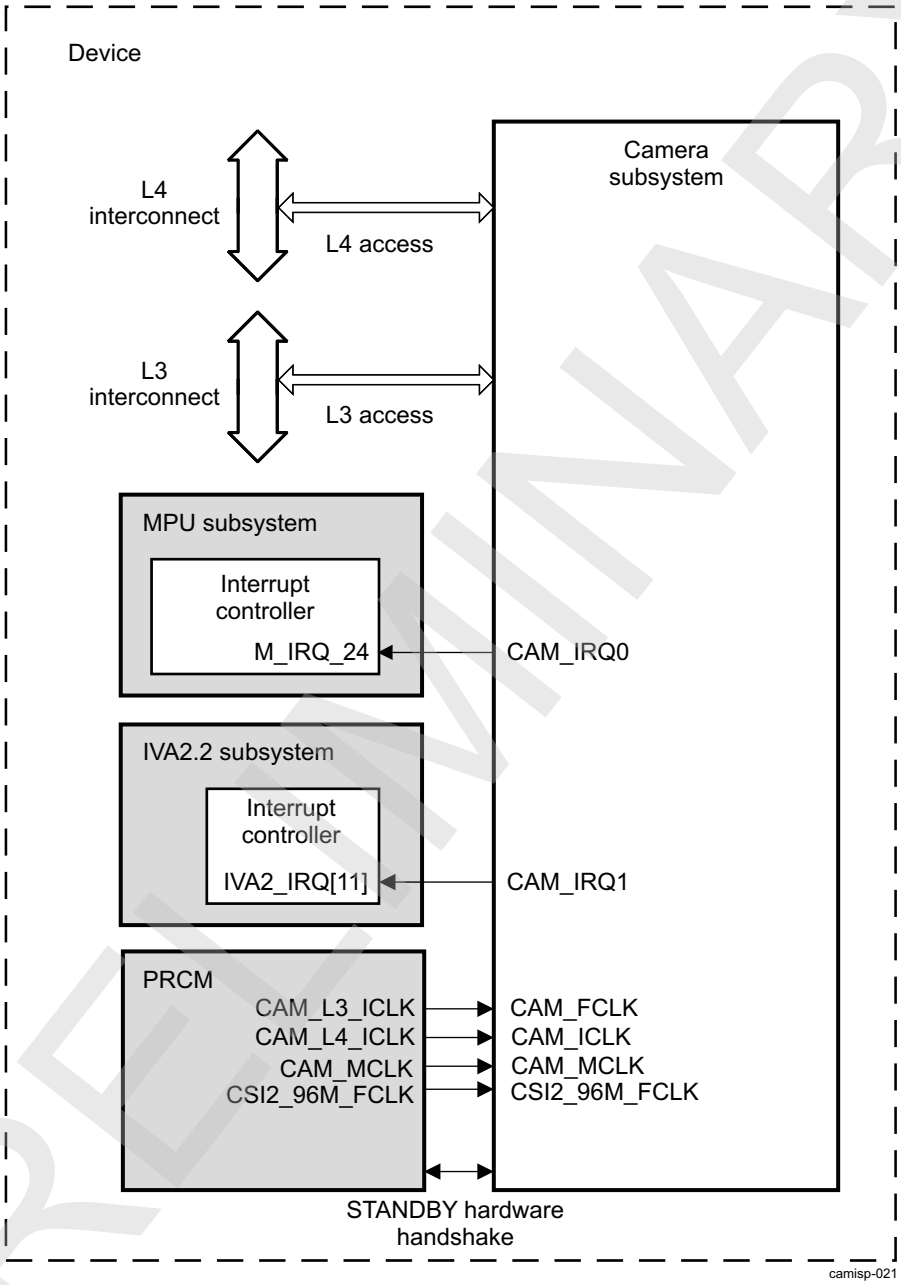
The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the CSI2_CTx_CTRL1[30] GENERIC bit. The CSI2_CTx_CTRL2[9:0] FORMAT register defines how the data stream is decoded. However, the MIPI® data type code is ignored. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI® virtual channel used in generic mode is only mapped to a single context. Software could optionally enable byte swapping of the payload data by setting the CSI2_CTx_CTRL1[31] BYTESWAP bit. This feature shall only be used when the amount of payload data per packet is a multiple of 16-bit. The byte swapping is performed before pixel reconstruction.

Figure 6-48. Camera ISP CSI2 Generic

6.3 Camera ISP Integration

Figure 6-49 shows the Camera ISP integration.

Figure 6-49. Camera ISP Integration



6.3.1 Camera ISP Clocking, Reset, and Power-Management Scheme

6.3.1.1 Camera ISP Clocks

There are six clock domains in the camera ISP:

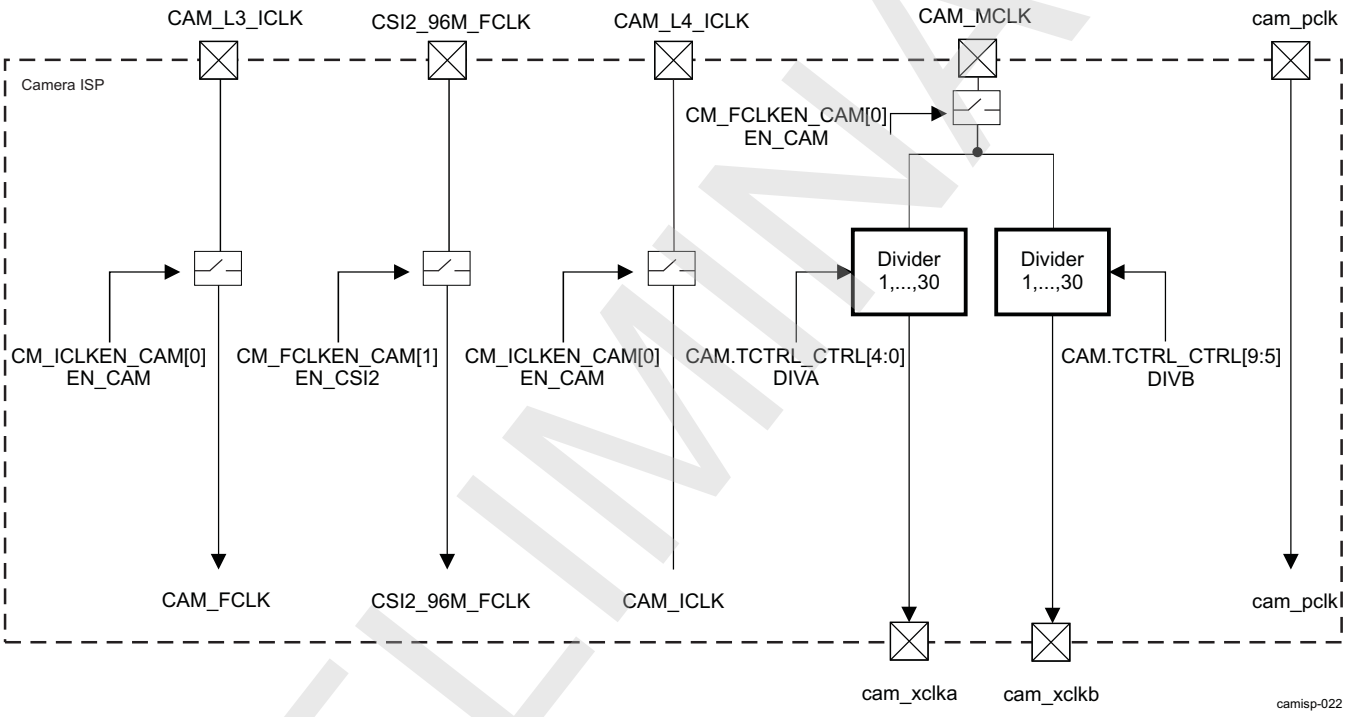
- Functional clock domain, this clock is from L3 interconnect along with Interface master write port clock. It is required to be 2x faster than the pixel clock.
- CSI1/CCP2B Serial interface clock domain. Only the parallel mode between the PHY's and the ISP is used.

- CSI2 Serial interface clock domain
- CSI2 byte clock domain, whitch frequency depends on the image sensor type and size, its frame rate and its blanking period. The clock is generated from the bit-clock from the sensor and converted into byte clock.
- Parallel interface clock domain. This frequency depends on the imaging sensor type and size, its frame rate and its blanking time. Note that the functional clock is required to be at least 2x faster than the pixel clock when the bridge is disabled and a least equal when it is enabled.
- Slave interface clock domain, from L4 interconnect

6.3.1.1.1 Camera ISP Clock Tree

Figure 6-50 shows the clock tree for the camera ISP module.

Figure 6-50. Camera ISP Clock Tree Diagram



6.3.1.1.2 Camera ISP Clock Descriptions

Table 6-12 describes the camera ISP clocks.

Table 6-12. Camera ISP Clock Descriptions

Signal Name	IO	Description
CAM_FCLK	Input	Functional clock (L3 interconnect clock domain) Functional clock domain.
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain) Interface clock domain.
CAM_MCLK(1)	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is used by the clock generator to generate cam_xclka and cam_xclkb. It is also used by the control Signal generator to generate cam_shutter, cam_strobe, and cam_global_reset. For more information, see Section 6.4.4, *Camera ISP Timing Control*.
cam_xclka	Output	External clock for the image-sensor module. For serial or parallel sensor.

(1) The CAM_MCLK frequency can be less than, or equal to 216 MHz.

Table 6-12. Camera ISP Clock Descriptions (continued)

Signal Name	IO	Description
cam_xclkb	Output	External clock for the image-sensor module. For serial or parallel sensor.
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. Parallel sensor clock domain.
CSI2_96M_FCLK	Input	CSI2 functional clock driven by PRCM.CM_FCLKEN_CAM[1] EN_CSI2.

6.3.1.1.3 Camera ISP Clock Configuration

- CSI2_96M_FCLK is the CSI2 functional clock running at 96 MHz and enabled when PRCM.CM_FCLKEN_CAM[1] EN_CSI2 = 1
- CAM_FCLK control and settings

  The CAM_FCLK clock runs at the device L3 clock frequency.

  The CAM_FCLK source is the PRCM CAM_L3_ICLK output.

  When the camera ISP no longer needs CAM_FCLK, the software can disable it at PRCM level by setting the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit to 0x0. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_FCLK from being cut while the module is processing or transferring data.

  An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_FCLK clock along with the CAM power domain at PRCM level. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
- CAM_ICLK control and settings:

  CAM_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM_L4_ICLK output.

  When the camera ISP no longer needs CAM_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit. Note that the clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, It does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_ICLK from being cut while the module is processing or transferring data.

  An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_ICLK clock along with the CAM power domain at PRCM level. For more information, see Chapter 3, *Power, Reset, and Clock Management*.
- CAM_MCLK control and settings:

  The source for CAM_MCLK is the PRCM CAM_MCLK output. It is generated trough a peripheral DPLL and its frequency can be adjusted using the PRCM.CM_CLKSEL_CAM[4:0] CLKSEL_CAM bit field. When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM_FCLKEN_CAM[0] EN_CAM bit to 0x0. Note that the PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM_MCLK is shut down.
  - cam_xclka and cam_xclkb control and settings:

    cam_xclka and cam_xclkb are generated inside the camera ISP module from CAM_MCLK clock input. Table 6-13 and Table 6-14 give the settings of the related bit fields.

Table 6-13. Camera ISP cam_xclka Configuration

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...

Table 6-13. Camera ISP cam_xclka Configuration (continued)

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
	0x1F	CAM_MCLK

Table 6-14. Camera ISP cam_xclkb Configuration

ref_clk	CAM.TCTRL_CTRL[9:5] DIVB field	cam_xclkb
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2
	...	...
	0x1F	CAM_MCLK

6.3.1.2 Camera ISP Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization
- A system power management

6.3.1.2.1 Camera ISP Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- ISP_SYSCONFIG [0] AUTO_IDLE bit to 1
- CCP2_SYSCONFIG [0] AUTO_IDLE bit to 1
- CSI2_SYSCONFIG [0] AUTO_IDLE bit to 1
- MMU.MMU_SYSCONFIG [0] AUTOIDLE bit to 1
- ISP_CTRL [21] SBL_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is enabled, by default.

NOTE: It is recommended that this mode be enabled to reduce power consumption.

6.3.1.2.2 Camera ISP System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to Chapter 3, *Power, Reset, and Clock Management* for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the ISP_SYSCONFIG [13:12] MIDLE_MODE bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDLE_MODE bit field allows the following settings for the camera ISP module:

- Force standby

  The camera ISP is set to force standby when MIDLE_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:

  – ISP_CTRL [13] RSZ_CLK_EN
  – ISP_CTRL [12] PRV_CLK_EN
  – ISP_CTRL [11] HIST_CLK_EN
  – ISP_CTRL [10] H3A_CLK_EN
  – ISP_CTRL [8] CCDC_CLK_EN

  Moreover, CSI2A and CSI2C receivers must also be disabled by setting the related CSI2_CTRL[0] IF_EN bits to 0x0 and CSI1/CCP2B must also be disabled by setting the related CCP2_CTRL [0] IF_EN bits to 0x0.
- No standby

  The camera ISP is set to no standby when MIDLE_MODE is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. Note that this also prevents the CAMERA power domain from going to a lower power state. Refer to Chapter 3, *Power, Reset, and Clock Management*, for further details.
- Smart standby

  The camera ISP module is set to smart standby when MIDLE_MODE is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no more data in the central resource buffer).

NOTE: CSI1/CCP2B receiver must also be configured to smart standby mode when the camera ISP is set to smart standby (CCP2_SYSCONFIG [13:12] MSTANDBY_MODE set to 0x2).

CSI2A and CSI2C receivers must also be configured to smart standby mode when the camera ISP is set to smart standby (CSI2_SYSCONFIG[13:12] MSTANDBY_MODE set to 0x2).

A standby request asserted to the PRCM does not necessarily lead to CAM_FCLK and CAM_ICLK being cut. The PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- PRCM.CM_ICLKEN_CAM[0] EN_CAM = 0 and PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0
- PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0, (PRCM.CM_ICLKEN_CAM[0] EN_CAM =1, PRCM.CM_AUTOIDLE_CAM[0] = 1, and a domain transition is required at PRCM level)

  See Chapter 3, *Power, Reset, and Clock Management*, for further details.

6.3.1.3 Camera ISP Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see Chapter 3, *Power, Reset, and Clock Management*.

6.3.1.4 Camera ISP Resets

6.3.1.4.1 Camera ISP Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the CAM_RST signal in the CAMERA domain (for more information, see Chapter 3, *Power, Reset, and Clock Management*).

6.3.1.4.2 Camera ISP Software Reset

A global software reset can be accomplished by setting the camera ISP ISP_SYSCONFIG [1] SOFT_RESET bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module, including CSI1/CCP2B,CSI2A, and CSI2C receivers.

NOTE: The CSI1/CCP2B receiver accepts a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.
The CSI1/CCP2B receiver can be reset by writing CCP2_SYSCONFIG [1] SOFT_RESET bit to 1. The software can monitor the CCP2_SYSSTATUS [0] RESET_DONE status bit to wait for the completion of the reset procedure.
If after 5 reads, CCP2_SYSSTATUS [0] RESET_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

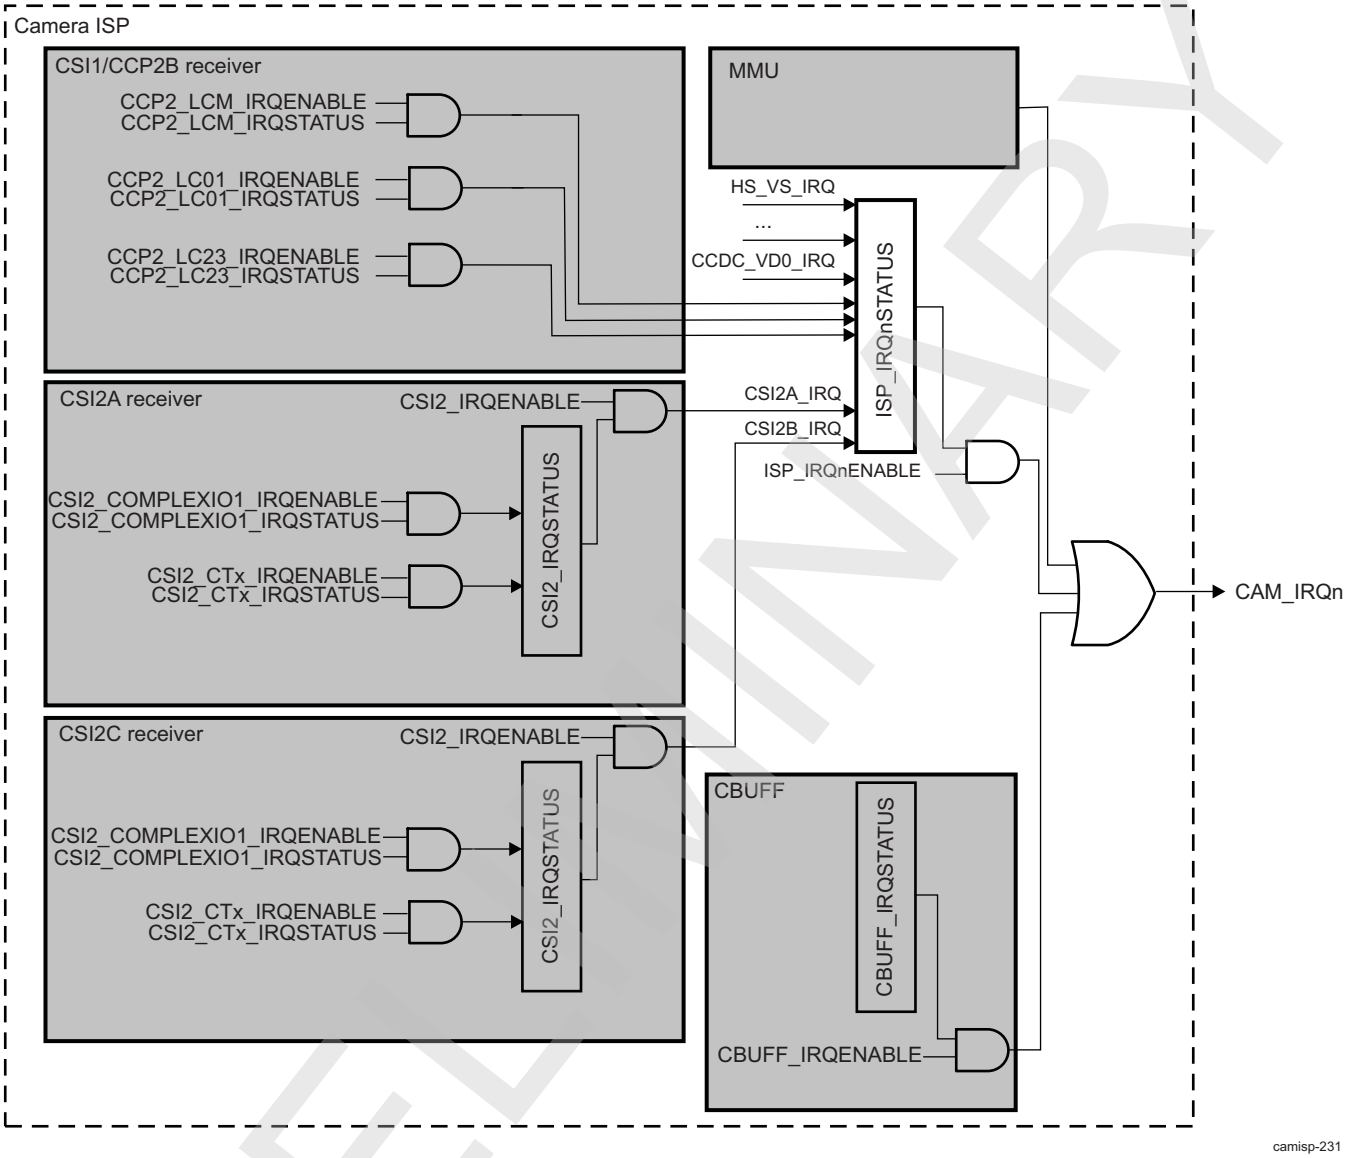
The CSI2A and CSI2C receivers accept a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.
The CSI2A and CSI2C receivers can be reset by writing CSI2_SYSCONFIG [1] SOFT_RESET bit to 1. The software can monitor the CSI2_SYSSTATUS [0] RESET_DONE status bit to wait for the completion of the reset procedure.
If after 5 reads, CSI2_SYSSTATUS [0] RESET_DONE still returns 0, it can be assumed that an error occurred during the reset stage.

6.3.2 Camera ISP Hardware Requests

6.3.2.1 Camera ISP Interrupt Requests

Figure 6-51 shows the interrupt generation tree of the camera subsystem.

Figure 6-51. Camera ISP Interrupt Generation Tree



(1) x = 0 to 7

The camera ISP can generate two interrupts:

- CAM_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_24.
- CAM_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2_IRQ[11].

Table 6-15 summarizes events that cause interrupts.

Table 6-15. Camera ISP Interrupts

Event	Mask	Description
ISP_IRQ0STATUS [31] HS_VS_IRQ	**ISP_IRQ0ENABLE [31] HS_VS_IRQ**	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the ISP_CTRL [15:14] SYNC_DETECT bit field.(1)
ISP_IRQ0STATUS [28] MMU_ERR_IRQ	**ISP_IRQ0ENABLE [28] MMU_ERR_IRQ**	MMU error

(1) This event is detected on the incoming HS/VS signals before the CCDC. Therefore, it cannot be used in BT656 mode.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [25] OVF_IRQ	ISP_IRQ0ENABLE [25] OVF_IRQ	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows
ISP_IRQ0STATUS [24] RSZ_DONE_IRQ	ISP_IRQ0ENABLE [24] RSZ_DONE_IRQ	RESIZER module. Resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
ISP_IRQ0STATUS [21] CBUFF_IRQ	ISP_IRQ0ENABLE [24] CBUFF_IRQ	CBUFF module event. See CBUFF_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [20] PRV_DONE_IRQ	ISP_IRQ0ENABLE [20] PRV_DONE_IRQ	PREVIEW module: Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [19] CCDC_LSC_PREFETCH_ERROR	ISP_IRQ0ENABLE [19] PRV_DONE_IRQ	CCDC module. The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after: 1) Clearing this event 2) Disabling the LSC module 3) Enabling it
ISP_IRQ0STATUS [18] CCDC_LSC_PREFETCH_COMPLETED	ISP_IRQ0ENABLE [18] CCDC_LSC_PREFETCH_COMPLETED	CCDC module. Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.
ISP_IRQ0STATUS [17] CCDC_LSC_DONE	ISP_IRQ0ENABLE [17] CCDC_LSC_DONE	CCDC module. The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
ISP_IRQ0STATUS [16] HIST_DONE_IRQ	ISP_IRQ0ENABLE [16] HIST_DONE_IRQ	HIST module. Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [13] H3A_AWB_DONE_IRQ	ISP_IRQ0ENABLE [13] H3A_AWB_DONE_IRQ	H3A module. Auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [12] H3A_AF_DONE_IRQ	ISP_IRQ0ENABLE [12] H3A_AF_DONE_IRQ	H3A module. Autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [11] CCDC_ERR_IRQ	ISP_IRQ0ENABLE [11] CCDC_ERR_IRQ	CCDC module. Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
ISP_IRQ0STATUS [10] CCDC_VD2_IRQ	ISP_IRQ0ENABLE [10] CCDC_VD2_IRQ	CCDC module. Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.
ISP_IRQ0STATUS [9] CCDC_VD1_IRQ	ISP_IRQ0ENABLE [9] CCDC_VD1_IRQ	CCDC module. Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [8] CCDC_VD0_IRQ	ISP_IRQ0ENABLE [8] CCDC_VD0_IRQ	CCDC module. Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [7] CSI1_LC3_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC3_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [6] CSI1_LC2_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC2_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [5] CSI1_LC1_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC1_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [4] CSI1_LC0_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC0_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [3] CSI1_LCM_IRQ	ISP_IRQ0ENABLE [3] CSI1_LCM_IRQ	CSI1 receiver module event on memory channel.
ISP_IRQ0STATUS [1] CSI2C_IRQ	ISP_IRQ0ENABLE [1] CSI2C_IRQ	CSI2C receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [0] CSI2A_IRQ	ISP_IRQ0ENABLE [0] CSI2A_IRQ	CSI2A receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.

NOTE: n is equal to 0 or 1.

I is equal to 01 or 23.

Table 6-16 summarizes the CBUFF interrupts.

Table 6-16. Camera ISP CBUFF Interrupt Details

Event	Mask	Description
CBUFF_IRQSTATUS [5] IRQ_CBUFF1_OVR	CBUFF_IRQENABLE [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the CBUFFx_CTRL.ALLOW_NW_EQ_CR flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.
CBUFF_IRQSTATUS [4] IRQ_CBUFF1_INVALID	CBUFF_IRQENABLE [4] IRQ_CBUFF1_INVALID	Invalid access: • Camera controller writes the virtual space of CBUFFx in read mode. • Camera controller reads the virtual space of CBUFFx in write mode. • HW writes the virtual space of circular buffer x outside the CW or NW window in write mode. • HW reads the virtual space of circular buffer x outside the CW or NW window in read mode. • NW full • CPU write the DONE bit when physical buffers are not ready for the CPU. This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory. The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.

Table 6-16. Camera ISP CBUFF Interrupt Details (continued)

Event	Mask	Description
CBUFF_IRQSTATUS [3] IRQ_CBUFF1_READY	CBUFF_IRQENABLE [3] IRQ_CBUFF1_READY	The CPUW1 physical buffer is ready to be accessed by the CPU.
CBUFF_IRQSTATUS [2] IRQ_CBUFF0_OVR	CBUFF_IRQENABLE [2] IRQ_CBUFF0_OVR	Buffer overflow event. See description of IRQ_CBUFF1_OVR event.
CBUFF_IRQSTATUS [1] IRQ_CBUFF0_INVALID	CBUFF_IRQENABLE [1] IRQ_CBUFF0_INVALID	Invalid access. See description of IRQ_CBUFF1_INVALID event.
CBUFF_IRQSTATUS [0] IRQ_CBUFF0_READY	CBUFF_IRQENABLE [0] IRQ_CBUFF0_READY	The CPUW1 physical buffer is ready to be accessed by the CPU

Table 6-17 describes the CSI1/CCP2B receiver interrupts.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details

Event	Mask	Description
CCP2_LC01_IRQSTATUS[27] LC1_FS_IRQ	CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ	Frame-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[26] LC1_LE_IRQ	CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ	Line-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[25] LC1_LS_IRQ	CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ	Line-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[24] LC1_FE_IRQ	CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ	Frame-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[23] LC1_COUNT_IRQ	CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ	Frame counter reached for logical channel 1: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC01_IRQSTATUS[21] LC1_FIFO_OVF_IRQ	CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ	FIFO overflow error for logical channel 1: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQSTATUS[20] LC1_CRC_IRQ	CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ	CRC error for logical channel 1: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC01_IRQSTATUS[19] LC1_FSP_IRQ	CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ	False synchronization code protection error for logical channel 1: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS[18] LC1_FW_IRQ	CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ	Frame-width error for logical channel 1: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC01_IRQSTATUS[17] LC1_FSC_IRQ	CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ	False synchronization code error for logical channel 1: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC01_IRQSTATUS[16] LC1_SSC_IRQ	CCP2_LC01_IRQENABLE[16]LC1_SSC_IRQ	Shifted synchronization code error for logical channel 1: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. (1)
CCP2_LC01_IRQSTATUS[11] LC0_FS_IRQ	CCP2_LC01_IRQENABLE[11] LC0_FS_IRQ	Frame-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[10] LC0_LE_IRQ	CCP2_LC01_IRQENABLE[10] LC0_LE_IRQ	Line-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[9] LC0_LS_IRQ	CCP2_LC01_IRQENABLE[9] LC0_LS_IRQ	Line-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[8] LC0_FE_IRQ	CCP2_LC01_IRQENABLE[8] LC0_FE_IRQ	Frame-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[7] LC0_COUNT_IRQ	CCP2_LC01_IRQENABLE[7] LC0_COUNT_IRQ	Frame counter reached for logical channel 0: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[5] LC0_FIFO_OVF_IRQ	CCP2_LC01_IRQENABLE[5] LC0_FIFO_OVF_IRQ	FIFO overflow error for logical channel 0: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC01_IRQSTATUS[4] LC0_CRC_IRQ	CCP2_LC01_IRQENABLE[4] LC0_CRC_IRQ	CRC error This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[3] LC0_FSP_IRQ	CCP2_LC01_IRQENABLE[3] LC0_FSP_IRQ	False synchronization code protection error for logical channel 0: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS[2] LC0_FW_IRQ	CCP2_LC01_IRQENABLE[2] LC0_FW_IRQ	Frame-width error for logical channel 0: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[1] LC0_FSC_IRQ	CCP2_LC01_IRQENABLE[1] LC0_FSC_IRQ	False synchronization code error for logical channel 0: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[0] LC0_SSC_IRQ	CCP2_LC01_IRQENABLE[0] LC0_SSC_IRQ	Shifted synchronization code error for logical channel 0: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. (2)
CCP2_LC23_IRQSTATUS[27] LC3_FS_IRQ	CCP2_LC23_IRQENABLE[27] LC3_FS_IRQ	Frame-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream

(1) This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1)
(2) This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1)

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS[26] LC3_LE_IRQ	CCP2_LC23_IRQENABLE[26] LC3_LE_IRQ	Line-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[25] LC3_LS_IRQ	CCP2_LC23_IRQENABLE[25] LC3_LS_IRQ	Line-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[24] LC3_FE_IRQ	CCP2_LC23_IRQENABLE[24] LC3_FE_IRQ	Frame-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[23] LC3_COUNT_IRQ	CCP2_LC23_IRQENABLE[23] LC3_COUNT_IRQ	Frame counter reached for logical channel 3: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC23_IRQSTATUS[21] LC3_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE[21] LC3_FIFO_OVF_IRQ	FIFO overflow error error for logical channel 3: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQSTATUS[20] LC3_CRC_IRQ	CCP2_LC23_IRQENABLE[20] LC3_CRC_IRQ	CRC error for logical channel 3: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC23_IRQSTATUS[19] LC3_FSP_IRQ	CCP2_LC23_IRQENABLE[19] LC3_FSP_IRQ	False synchronization code protection error for logical channel 3: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS[18] LC3_FW_IRQ	CCP2_LC23_IRQENABLE[18] LC3_FW_IRQ	Frame-width error for logical channel 3: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC23_IRQSTATUS[17] LC3_FSC_IRQ	CCP2_LC23_IRQENABLE[17] LC3_FSC_IRQ	False synchronization code error for logical channel 3: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state machine.
CCP2_LC23_IRQSTATUS[16] LC3_SSC_IRQ	CCP2_LC23_IRQENABLE[16] LC3_SSC_IRQ	Shifted synchronization code error for logical channel 3: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. (3)
CCP2_LC23_IRQSTATUS[11] LC2_FS_IRQ	CCP2_LC23_IRQENABLE[11] LC2_FS_IRQ	Frame-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[10] LC2_LE_IRQ	CCP2_LC23_IRQENABLE[10] LC2_LE_IRQ	Line-end synchronization code detection detection for logical channel 2: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.

(3) This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1)

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS[9] LC2_LS_IRQ	CCP2_LC23_IRQENABLE[9] LC2_LS_IRQ	Line-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[8] LC2_FE_IRQ	CCP2_LC23_IRQENABLE[8] LC2_FE_IRQ	Frame-end synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[7] LC2_COUNT_IRQ	CCP2_LC23_IRQENABLE[7] LC2_COUNT_IRQ	Frame counter reached for logical channel 2: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[5] LC2_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE[5] LC2_FIFO_OVF_IRQ	FIFO overflow error for logical channel 2: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC23_IRQSTATUS[4] LC2_CRC_IRQ	CCP2_LC23_IRQENABLE[4] LC2_CRC_IRQ	CRC error for logical channel 2: This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[3] LC2_FSP_IRQ	CCP2_LC23_IRQENABLE[3] LC2_FSP_IRQ	False synchronization code protection error for logical channel 2: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS[2] LC2_FW_IRQ	CCP2_LC23_IRQENABLE[2] LC2_FW_IRQ	Frame-width error for logical channel 2: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[1] LC2_FSC_IRQ	CCP2_LC23_IRQENABLE[1] LC2_FSC_IRQ	False synchronization code error error for logical channel 2: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS[0] LC2_SSC_IRQ	CCP2_LC23_IRQENABLE[0] LC2_SSC_IRQ	Shifted synchronization code error for logical channel 2: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. (4)
CCP2_LCM_IRQSTATUS[1] LCM_OCPERROR	CCP2_LCM_IRQENABLE[1] LCM_OCPERROR	An OCP error occurred on the master read port. This interrupt is triggered on the detection of an OCP error on the master read port.
CCP2_LCM_IRQSTATUS[0] LCM_EOF	CCP2_LCM_IRQENABLE[0] LCM_OEF	Memory read channel end of frame: This interrupt is triggered when a frame has been completely read from memory.

(4) This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1)

Table 6-18 shows CSI2A and CSI2C receivers event generation through the CSI2 interrupt status and interrupt enable registers.

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation

Event	Mask	Description
CSI2_IRQSTATUS[0] CONTEXT0	CSI2_IRQENABLE[0] CONTEXT0	At least one interrupt event enabled from Context 0 occurred (see Table 6-20).
CSI2_IRQSTATUS[1] CONTEXT1	CSI2_IRQENABLE[1] CONTEXT1	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS[2] CONTEXT2	CSI2_IRQENABLE[2] CONTEXT2	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS[3] CONTEXT3	CSI2_IRQENABLE[3] CONTEXT3	At least one interrupt event enabled from Context 3 occurred (see Table 6-20).

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation (continued)

Event	Mask	Description
CSI2_IRQSTATUS[4] CONTEXT4	CSI2_IRQENABLE[4] CONTEXT4	At least one interrupt event enabled from Context 4 occurred (see Table 6-20).
CSI2_IRQSTATUS[5] CONTEXT5	CSI2_IRQENABLE[5] CONTEXT5	At least one interrupt event enabled from Context 5 occurred (see Table 6-20).
CSI2_IRQSTATUS[6] CONTEXT6	CSI2_IRQENABLE[6] CONTEXT6	At least one interrupt event enabled from Context 6 occurred (see Table 6-20).
CSI2_IRQSTATUS[7] CONTEXT6	CSI2_IRQENABLE[7] CONTEXT7	At least one interrupt event enabled from Context 7 occurred (see Table 6-20).
CSI2_IRQSTATUS[8] FIFO_OVF_IRQ	CSI2_IRQENABLE[8] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered on detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly.
CSI2_IRQSTATUS[9] PHY_ERR_IRQ	CSI2_IRQENABLE[9] PHT_ERR_IRQ	Error signaling from PHY: This interrupt is triggered when any error is received from the PHY (events are defined in CSI2_COMPLEXIO1_IRQSTATUS [see Table 6-19]).
CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (short packet only).
CSI2_IRQSTATUS[13] SHORT_PACKET_IRQ	CSI2_IRQENABLE[13] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types between 0x8 and 0xF are considered).
CSI2_IRQSTATUS[14] OCP_ERR_IRQ	CSI2_IRQENABLE[14] OCP_ERR_IRQ	OCP error

Table 6-19 shows CSI2A and CSI2C receiver event generation interrupt status and interrupt enable registers receiving signals from the associated PHY.

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY

Event	Mask	Description
CSI2_COMPLEXIO1_IRQSTATUS[0] ERRSOTHS1	CSI2_COMPLEXIO1_IRQENABLE[0] ERRSOTHS1	Start of transmission error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[1] ERRSOTHS2	CSI2_COMPLEXIO1_IRQENABLE[1] ERRSOTHS2	Start of transmission error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[2] ERRSOTHS3	CSI2_COMPLEXIO1_IRQENABLE[2] ERRSOTHS3	Start of transmission error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[5] ERRSOTSYNCHS1	CSI2_COMPLEXIO1_IRQENABLE[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[6] ERRSOTSYNCHS2	CSI2_COMPLEXIO1_IRQENABLE[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[7] ERRSOTSYNCHS3	CSI2_COMPLEXIO1_IRQENABLE[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[10] ERRESC1	CSI2_COMPLEXIO1_IRQENABLE[10] ERRESC1	Escape entry error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[11] ERRESC2	CSI2_COMPLEXIO1_IRQENABLE[11] ERRESC2	Escape entry error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[12] ERRESC3	CSI2_COMPLEXIO1_IRQENABLE[12] ERRESC3	Escape entry error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[15] ERRCONTROL1	CSI2_COMPLEXIO1_IRQENABLE[15] ERRCONTROL1	Control error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[16] ERRCONTROL2	CSI2_COMPLEXIO1_IRQENABLE[16] ERRCONTROL2	Control error for lane 2

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY (continued)

Event	Mask	Description
CSI2_COMPLEXIO1_IRQSTATUS[17] ERRCONTROL3	CSI2_COMPLEXIO1_IRQENABLE[17] ERRCONTROL3	Control error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[20] STATEULPM1	CSI2_COMPLEXIO1_IRQENABLE[20] STATEULPM1	Lane 1 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[21] STATEULPM2	CSI2_COMPLEXIO1_IRQENABLE[21] STATEULPM2	Lane 2 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[22] STATEULPM3	CSI2_COMPLEXIO1_IRQENABLE[22] STATEULPM3	Lane 3 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[25] STATEALLULPMENTER	CSI2_COMPLEXIO1_IRQENABLE[25] STATEALLULPMENTER	All active lanes are entering in ULPM.
CSI2_COMPLEXIO1_IRQSTATUS[26] STATEALLULPMEXIT	CSI2_COMPLEXIO1_IRQENABLE[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

As the CSI2A and CSI2C receivers supports eight contexts, the CSI2_CTx_IRQSTATUS and CSI2_CTx_IRQENABLE registers are present eight times (one time per context).

The events are generated only for the enabled context(s). Table 6-20 describes the CSI2A and CSI2C receiver event generation through the CTx interrupt status and interrupt enable registers.

Table 6-20. Camera ISP CSI2A and CSI2C CTx Receiver Event Generation

Event	Mask	Description
CSI2_CTx_IRQSTATUS[0] FS_IRQ	CSI2_CTx_IRQENABLE[0] FS_IRQ	Frame start: This interrupt is triggered on the detection of a frame-start synchronization code into the CSI2 data stream.
CSI2_CTx_IRQSTATUS[1] FE_IRQ	CSI2_CTx_IRQENABLE[1] FE_IRQ	Frame end: This interrupt is triggered on the detection of a frame-end synchronization code into the CSI2 data stream.
CSI2_CTx_IRQSTATUS[2] LS_IRQ	CSI2_CTx_IRQENABLE[2] LS_IRQ	Line start: This interrupt is triggered on the detection of a line-start synchronization code into the CSI2 data stream.
CSI2_CTx_IRQSTATUS[3] LE_IRQ	CSI2_CTx_IRQENABLE[3] LE_IRQ	Line end: This interrupt is triggered on the detection of a line-end synchronization code into the CSI2 data stream.
CSI2_CTx_IRQSTATUS[5] CS_IRQ	CSI2_CTx_IRQENABLE[5] CS_IRQ	CS error: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums (payload).
CSI2_CTx_IRQSTATUS[6] FRAME_NUMBER_IRQ	CSI2_CTx_IRQENABLE[6] FRAME_NUMBER_IRQ	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
CSI2_CTx_IRQSTATUS[7] LINE_NUMBER_IRQ	CSI2_CTx_IRQENABLE[7] LINE_NUMBER_IRQ	Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTx_CTRL1.LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTx_CTRL3.LINE_NUMBER); otherwise, the interrupt is generated only for the line number.
CSI2_CTx_IRQSTATUS[8] ECC_CORRECTION_IRQ	CSI2_CTx_IRQENABLE[8] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (long packets only).

6.4 Camera ISP Functional Description

6.4.1 Camera ISP Block Diagram

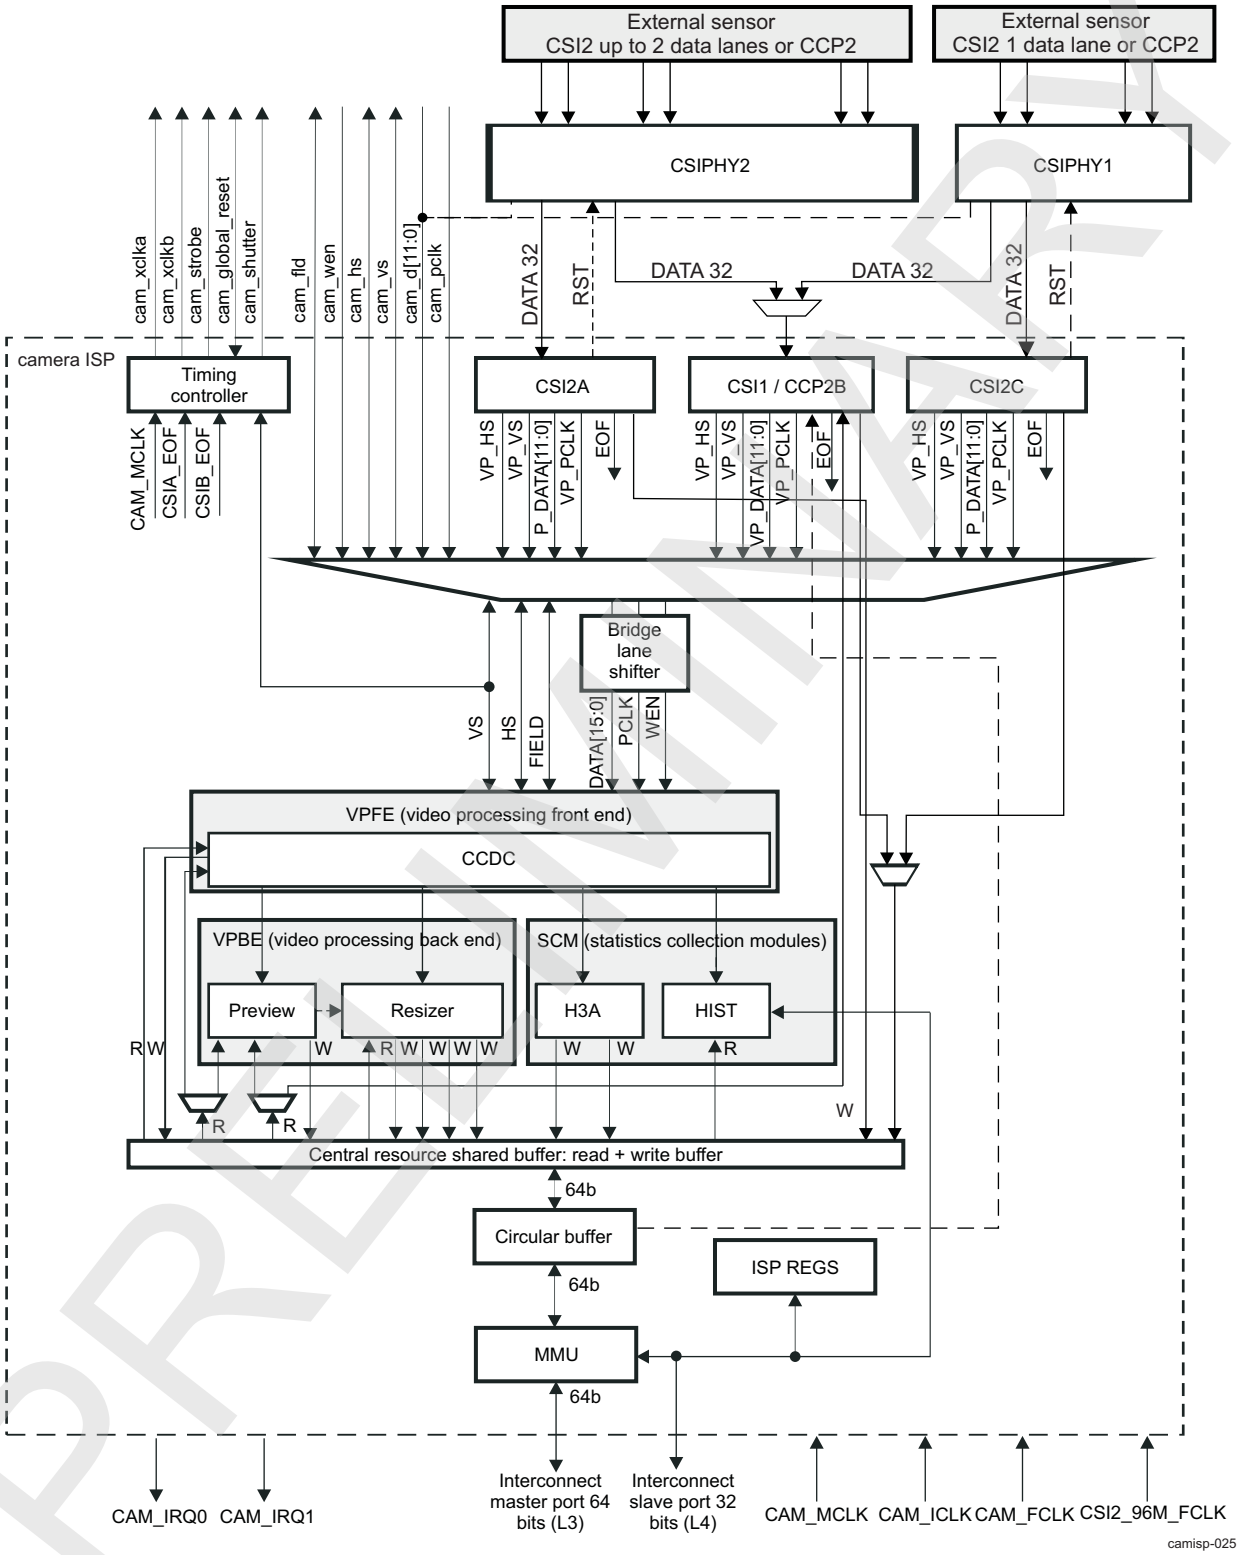
Figure 6-52 is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the Video processing hardware at a time.

See Section 6.2.3 for connectivity configurations and limitations details.

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

Figure 6-52 shows the camera ISP block diagram.

Figure 6-52. Camera ISP Block Diagram



The camera ISP module comprises the following blocks:

- Timing control: Includes a timing generator and a control-signal generator:
  - The timing generator allows the generation of two clocks that can be used by the external image sensors.

  - The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Three CSI receivers (one CCP2/MIPI® CSI1 and two MIPI® CSI2): The CSI receivers communicate with a serial camera through the PHY's and transfers received data to memory or to the Video processing hardware.
- Bridge-lane shifter:
  - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
  - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- Video-processing front end (VPFE): Comprises the CCDC. This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
  - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- Video-processing back end (VPBE): Comprises preview and resizer modules:
  - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
  - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
  - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
  - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

6.4.1.1 Camera ISP Possible Data Paths Inside the module

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

Table 6-21 lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC. It is the internal parallel format.

Table 6-21. Camera ISP Allowed Data Flows for Hardware

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Bridge lane shifter				X
CCDC BT 656 decoder			x	
CCDC DC substract	x	x	x	x
CCDC Optical Black clamp	x	x		
CCDC Faulty pixel correction	x	x		
CCDC Data formatter	x			
CCDC Preview, H3A, Histogram data paths	x			

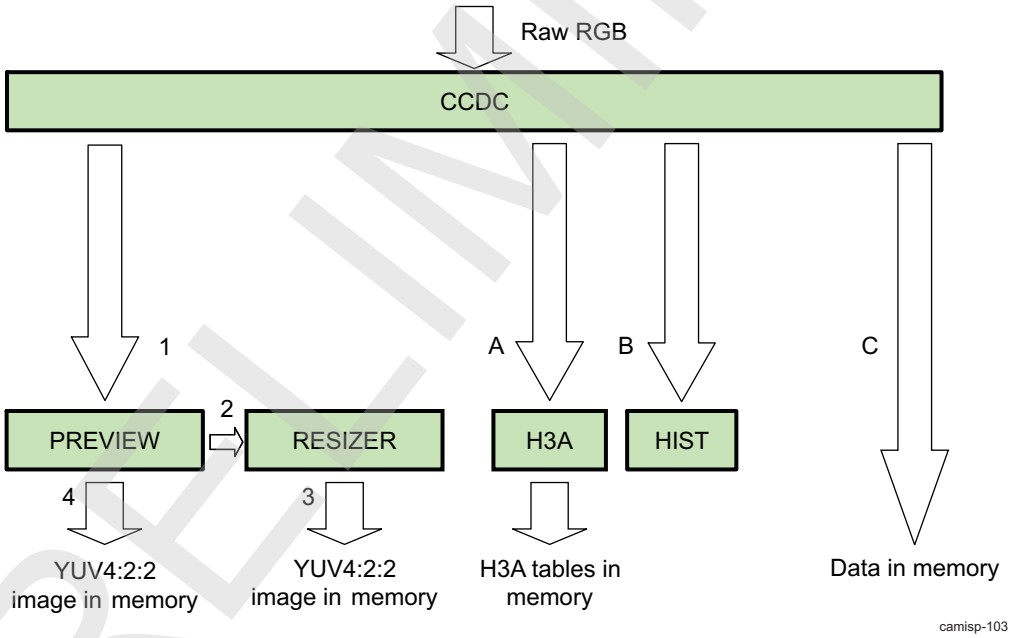
Table 6-21. Camera ISP Allowed Data Flows for Hardware (continued)

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Output formatter	x	x	x	x
CCDC Low pass filter	x	x		
CCDC Culling	x	x	x	x
CCDC Alaw	x	x		
CCDC Resizer Datapath			x	x
CCDC Memory Datapath	x	x	x	x
CCDC Shading compensator	x			
Preview	x			
Resizer	x		x	x
H3A	x			
Histogram	x			

6.4.1.1.1 Camera ISP RGB RAW Data

Figure 6-53 shows the data path of images in RAW format.

Figure 6-53. Camera ISP/Data Path/RAW RGB Images



RAW data are processed through the CCDC module and are directly pipelined to the preview engine(1). Another way is to output directly from the CCDC to memory (C) In the preview block; the format is converted from RAW data to YUV4:2:2. The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

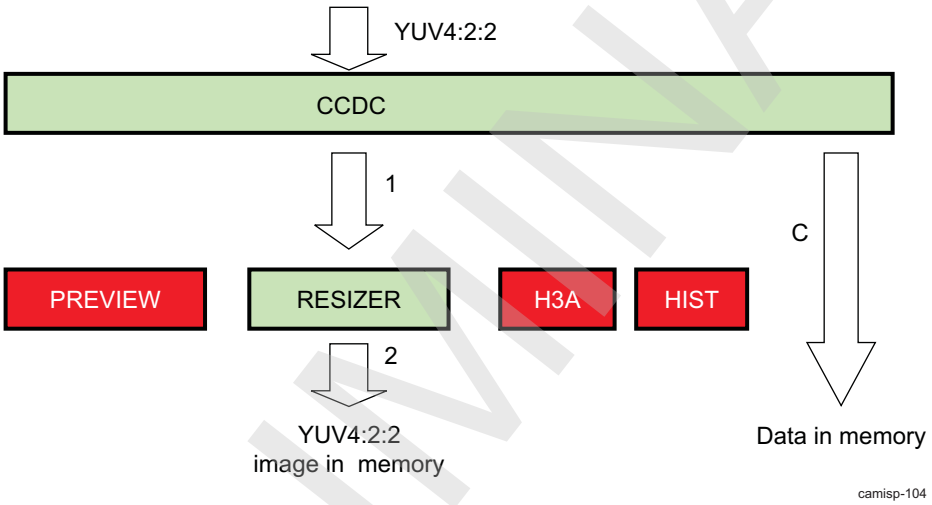
NOTE:

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory (C).
- RAW12 data must be sent to memory (C) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory (C) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

6.4.1.1.2 Camera ISP YUV4:2:2 Data

Figure 6-54 shows the data path of images in YUV4:2:2 format.

Figure 6-54. Camera ISP / Data Path/YUV4:2:2 Images



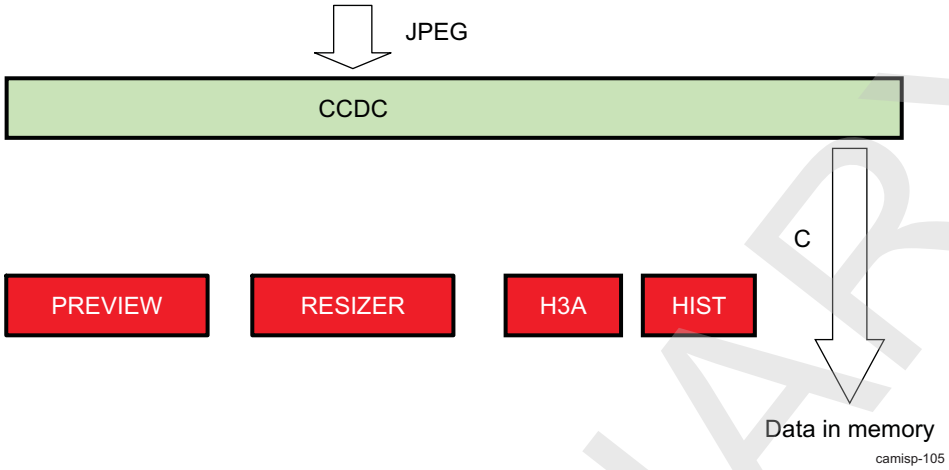
When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (C). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in Figure 6-54 are not used when the format is YUV4:2:2.

6.4.1.1.3 JPEG Data

Figure 6-55 shows the data path of images in JPEG format.

Figure 6-55. Camera ISP/Data Path/JPEG Images



When the sensor output format is JPEG, the CCDC block is directly output to the memory (C).

The modules in red in Figure 6-55 are not used when the format is JPEG.

6.4.2 Camera ISP CSI1/CCP2B Receiver

The CSI1 / CCP2B receiver is compatible with the CCP2 specification and the MIPI® CSI1 specification.

6.4.2.1 Camera ISP CSI1/CCP2B Receiver Features

The CSI1/CCP2B receiver features are listed below:

- Image from sensor
  - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
  - Unidirectional data link
  - 1D and 2D addressing mode
  - False synchronization code protection
  - Ping-pong mechanism for double-buffering
  - Support of RGB, RAW, YUV, and JPEG formats
  - Support of DPCM compression and decompression
- Image read from memory
  - RAW formats supported

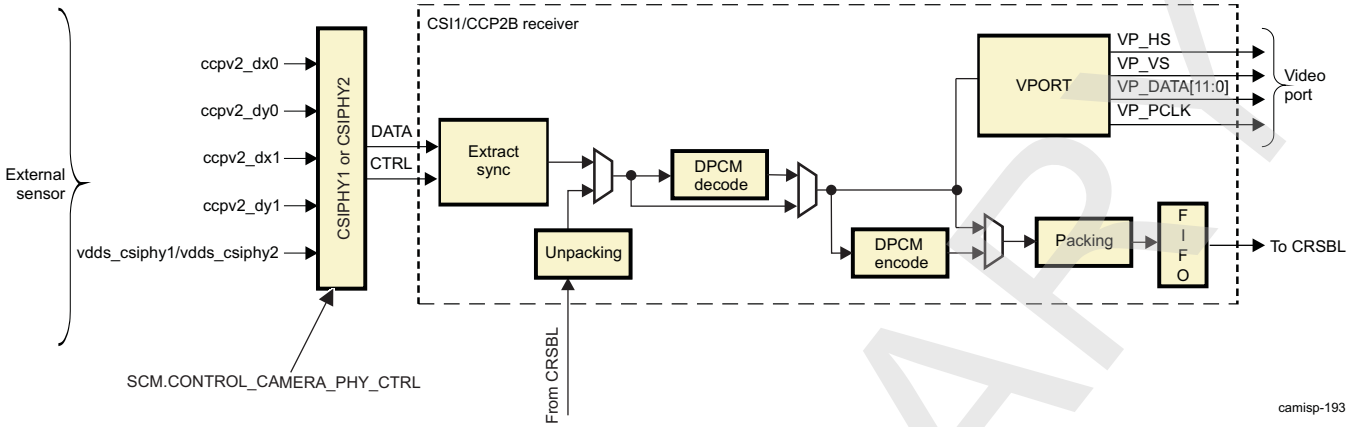
6.4.2.2 Camera ISP CSI1/CCP2B Receiver Functional Description

6.4.2.2.1 Camera ISP CSI1/CCP2B Overview

Figure 6-56 is the CSI1/CCP2B receiver top-level block diagram. The CSI1/CCP2B receiver takes serial data from a CSI1/CCP2B-compatible image sensor through the selected PHY, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it to the Video processing hardware or to memory.

The CSI1/CCP2B receiver video-port interface is connected to the Video processing hardware.

Figure 6-56. Camera ISP CSI1/CCP2B Receiver Block Diagram



6.4.2.2.2 Camera ISP CSI1/CCP2B Associated PHY

The CSI1/CCP2B receiver's selected PHY is controlled by 2 bits of the CCP2_CTRL register:

- The CCP2_CTRL[2] IO_OUT_SEL bit selects the output mode of the PHY which must be set to 1 for parallel.

CAUTION

CCP2_CTRL[2] IO_OUT_SEL bit must be set to 1(parallel mode) after reset and at normal work flow . If not set it could couse ISP functional stall.

- The CCP2_CTRL[10] INV bit selects the clock edge used to sample data:
  - If CCP2_CTRL[10] INV = 0x0, use the rising edge.
  - If CCP2_CTRL[10] INV = 0x1, use the falling edge.

The CSI1/CCP2B receiver associated configured PHY is controlled by a SCM registers: SCM.CONTROL_CAMERA_PHY_CTRL

- SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel:
  - CSIPHY1 data is sent to ISP CSI1/ CCP2B if set to 0
  - CSIPHY2 data is sent to ISP CSI1/ CCP2B if set to 1

For information about initializing the CSIPHY associated with CSI1/CCP2B, see Section 6.5.2.2, *Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver*.

See Section 6.2.3 for further connectivity schema details.

6.4.2.2.3 Camera ISP CSI1/CCP2B Physical Layer

The CSI1/CCP2B serial interface is a unidirectional differential serial interface with two options for the physical layer: data/clock or data/strobe signals. The physical layer of the CSI1/CCP2B is based on SubLVDS signaling.

CCP2B defines three classes for data transfer between the transmitter and the receiver. Table 6-22 summarizes the CSI1/CCP2B classifications. Class 1 and class 2 do not apply to the MIPI® CSI1-compatible mode.

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification

Class	Data Transfer Capacity	Signaling Method
Class 0 (CSI1/CCP2)	< 208 Mbps	Data/clock
Class 1 (CCP2 only)	208 Mbps to < 416 Mbps	Data/strobe

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification (continued)

Class	Data Transfer Capacity	Signaling Method
Class 2 (CCP2 only)	416 Mbps to < 650 Mbps	Data/strobe

6.4.2.2.3.1 Camera ISP CSI1/CCP2B Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and clock.

- The data signal carries bit-serial data. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The data are usually transmitted bytewise, LSB first.
- The data clock signal carries the clock signal. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The CSI1/CCP2B receiver reads the data on the rising edge of the clock.

6.4.2.2.3.2 Camera ISP CSI1/CCP2B Data/Strobe Signaling (CCP2 only)

Data/strobe signaling consists of two parallel signals: data and strobe.

- The data signal carries the bit-serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state.

  Either the data signal or the strobe signal changes between two data bits. The data and strobe signals may not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data.

6.4.2.2.4 Camera ISP CSI1/CCP2B Protocol Layer

The CSI1/CCP2B protocol layer defines how image-sensor data are transported to the physical layer.

The CSI1/CCP2B protocol layer transports logical channels, which are composed of frames. A frame comprises embedded data and image-sensor data. Each frame is clearly identified by unique synchronization codes: frame start, frame end, line start, and line end. Image-sensor data can have multiple data types (select the data type in the CCP2_LCx_CTRL [7:2] FORMAT bit field [x = 0 to 3]). For details about data types, synchronization code, and FSP encoding/decoding, see Section 6.2.4.4, *Camera ISP CSI1/CCP2 Protocol and Data Formats*.

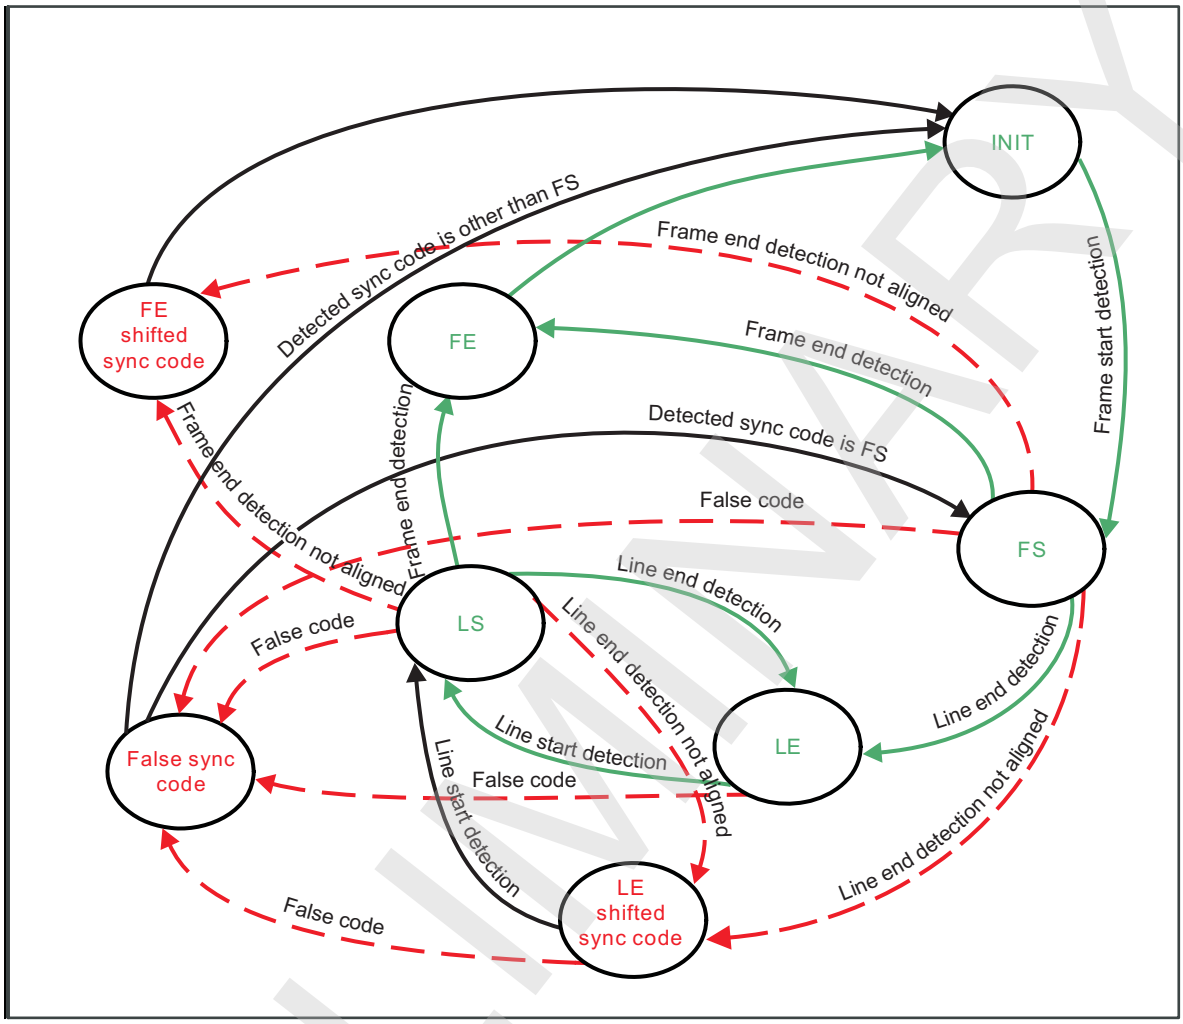
6.4.2.2.4.1 Camera ISP CSI1/CCP2B Synchronization Finite State-Machine

Figure 6-57 shows the CSI1/CCP2B receiver finite state-machine (FSM). The CSI1/CCP2B receiver synchronization operates bitwise.

The expected synchronization code order is FSC, LEC, LSC, and LEC...etc., LSC, LEC, LSC, FEC for all data types except JPEG8. For JPEG8, the expected synchronization code order is FSC, FEC.

If the synchronization code order is not respected, the state-machine goes to FalseSyncCode state. Because line length is always a multiple of 32 bits, the LEC and FEC codes are always aligned on a 32-bit boundary. If LEC or FEC is not aligned on a 32-bit boundary, the state-machine goes to LEShiftedSyncCode or FEShiftedSyncCode state. Figure 6-57 shows the synchronization state-machine.

Figure 6-57. Camera ISP CSI1/CCP2B Synchronization State-Machine



In case of synchronization code errors, the CSI1/CCP2B receiver can reinitialize itself. No software intervention is required for most synchronization-code errors:

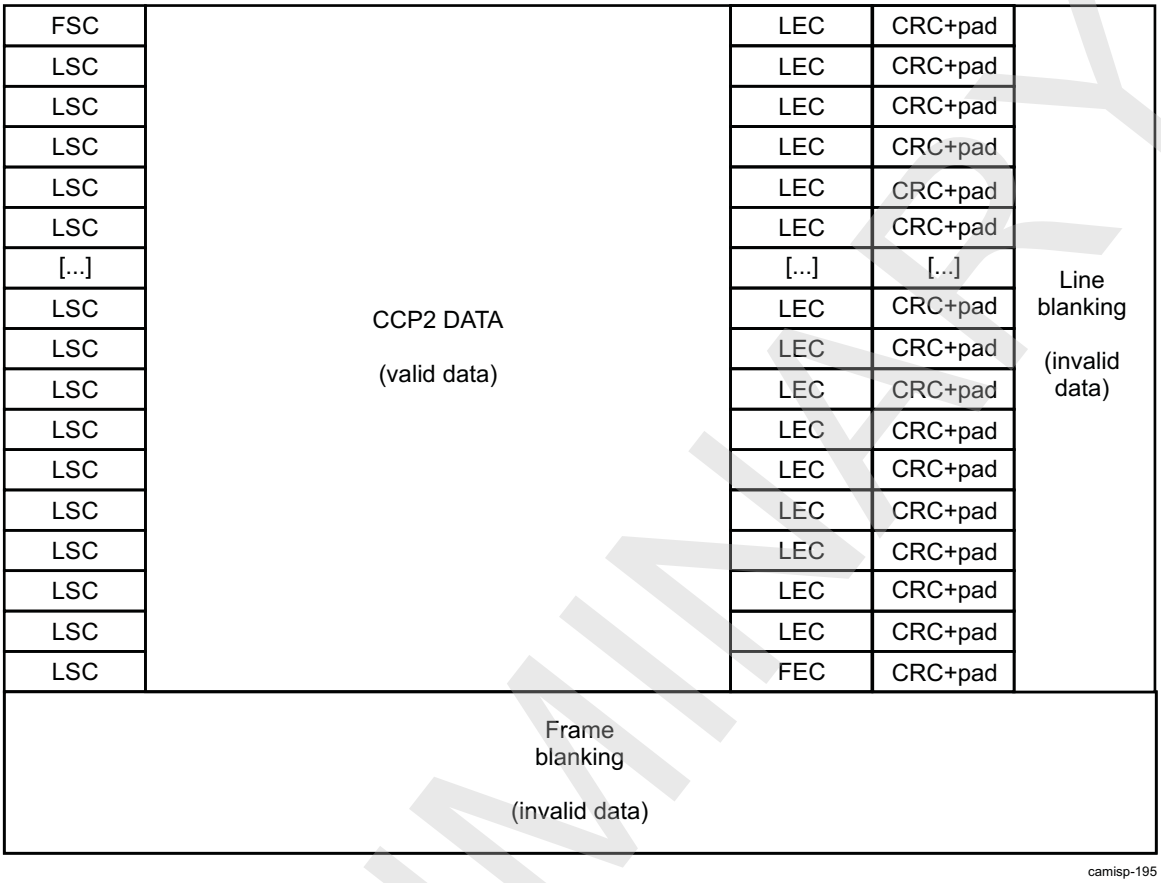
- Line-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next LS synchronization code resynchronizes the state-machine to normal behavior. A shifted line-end (LE) synchronization code triggers an LE_IRQ event.
- Frame-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next FS synchronization code resynchronizes the state-machine to normal behavior. A shifted frame-end (FE) synchronization code triggers an FE_IRQ event.
- False synchronization code: The current frame is lost. The receiver stops acquiring data, flushes its internal FIFO, and asserts the FSC_IRQ event. The next FS synchronization code resynchronizes the state-machine to normal behavior.

6.4.2.2.4.1.1 Camera ISP CSI1/CCP2B Frames

Structure

Figure 6-58 shows the generic (non-JPEG) description of a CSI1/CCP2B frame with synchronization codes. Each CSI1/CCP2B frame line is composed of a finite number of 32-bit words.

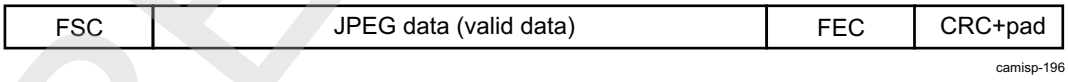
Figure 6-58. Camera ISP CSI1/CCP2B Frame Structure: Non-JPEG Data Format



The period between LEC and new is called the line-blanking period. The time between FEC and new FSC is called the frame-blanking period. The CSI1/CCP2B receiver works with line-blanking periods set to 0 or longer.

Figure 6-59 shows CSI1/CCP2B frame structure for the JPEG8 case. The JPEG stream is composed of a finite number of 32-bit words. LSC and LEC synchronization codes are never used when the CSI1/CCP2B interface transports a JPEG bitstream; only FSC and FEC synchronization codes are used.

Figure 6-59. Camera ISP CSI1/CCP2B Frame Structure: JPEG8 Data Format



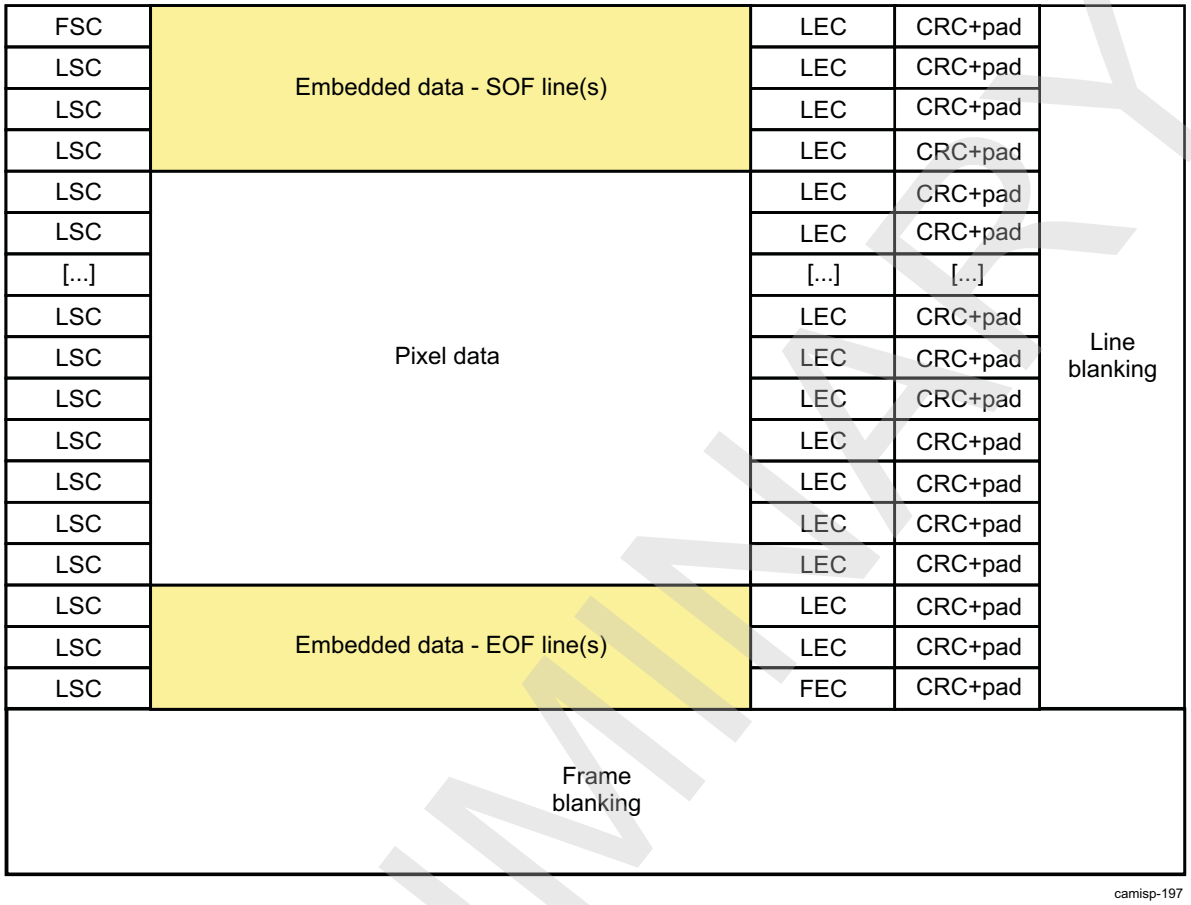
Data

A frame comprises embedded data and image-sensor data. Figure 6-60 shows the location of embedded data and image-sensor data in the frame. The following definitions apply:

- 0 or more start-of-frame (SOF) status lines can be embedded at the beginning of a CSI1/CCP2B frame.
- Image data comprises pixels of the same data formats. It may contain visible or nonvisible pixels.
- 0 or more end-of-frame (EOF) status line(s) can be embedded at the end of a CSI1/CCP2B frame.
- SOF lines, pixel data, and EOF lines do not overlap.

The CSI1/CCP2B receiver does not use the information contained in the status lines. However, it extracts it and stores it in memory for use by the software. Figure 6-60 shows the CSI1/CCP2B data structure.

Figure 6-60. Camera ISP CSI1/CCP2B Data Structure



Embedded information (SOF and EOF lines):

- Embedded information is never compressed (no DPCM).
- Embedded information covers full lines.
- Embedded information is not encoded in the same data format as pixel data. The CSI1/CCP2B receiver extracts embedded information, but does not modify the data format.
- False-synchronization-code protection is implemented; the receiver ensures that the embedded data contains no synchronization codes.

Pixel data:

- Pixel data can be compressed.
- Pixel data comprises pixels of the same data format.
- False-synchronization-code protection is implemented; the receiver ensures that the pixel data contains no synchronization codes.

6.4.2.2.4.1.2 Camera ISP CSI1/CCP2B Logical Channels

Identification

The CCP2B protocol layer transports logical channels. The purpose of logical channels is to separate different data flows that are interleaved in the same data stream. Each logical channel is identified by a unique channel identification number.

The channel identification number is directly encoded in the 32-bit synchronization codes. Logical channels do apply to the MIPI® CSI1 compatible mode; only one channel (channel 0) is used.

As shown in Figure 6-56, the CCP2B receiver monitors the channel identification number and demultiplexes the interleaved data streams. The CCP2B receiver supports up to four concurrent logical channels.

The logical channel identifier is coded in the upper 4 bits (bits 4 to 7) of the last byte of the synchronization codes. Table 6-23 summarizes the default logical channel values used for each channel. The CCP2B programming model allows these values to be overwritten.

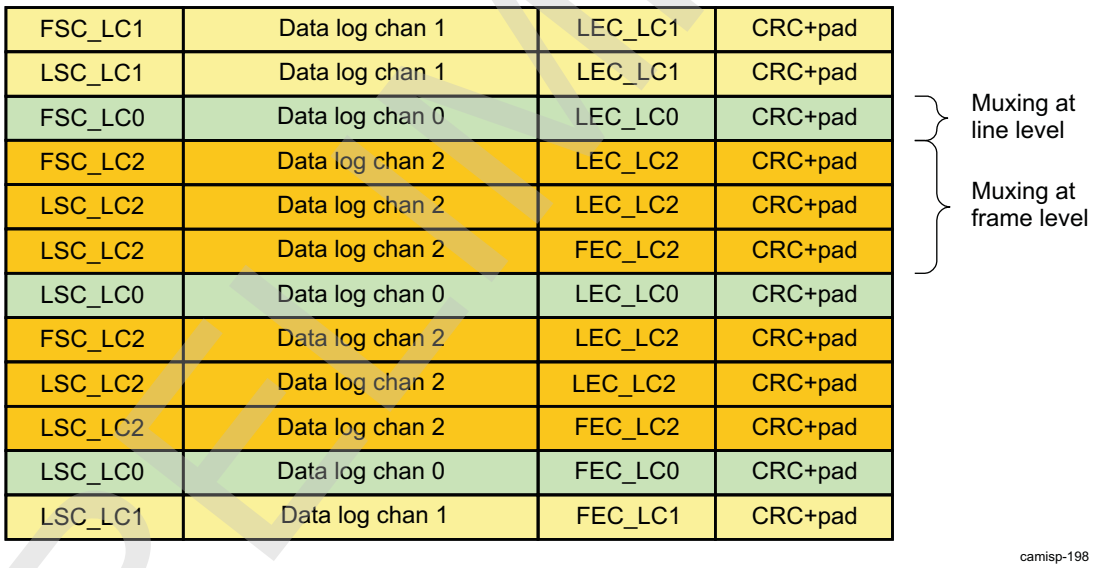
Table 6-23. Camera ISP CSI1/CCP2B Logical Channel Values in Synchronization Codes

Logical Channel	Value
Logical channel 0	0x0
Logical channel 1	0x1
Logical channel 2	0x2
Logical channel 3	0x3
Logical channel 4	0x4
Logical channel 5	0x5
Logical channel 6	0x6
Logical channel 7	0x7

Muxing

The logical channels are interleaved at the line level or at the frame level. Figure 6-61 shows the possible situations. Each logical channel can use different data formats.

Figure 6-61. Camera ISP CSI1/CCP2B Muxing



6.4.2.2.5 Camera ISP CSI1/CCP2B Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM decompressed if necessary.
- Can send the data to the Video processing hardware
- Can send the data back to memory. It can be DPCM compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

Table 6-24 summarizes supported modes for memory-to-memory operations.

Table 6-24. Camera ISP CSI1/CCP2B Memory-to-Memory Supported Operations

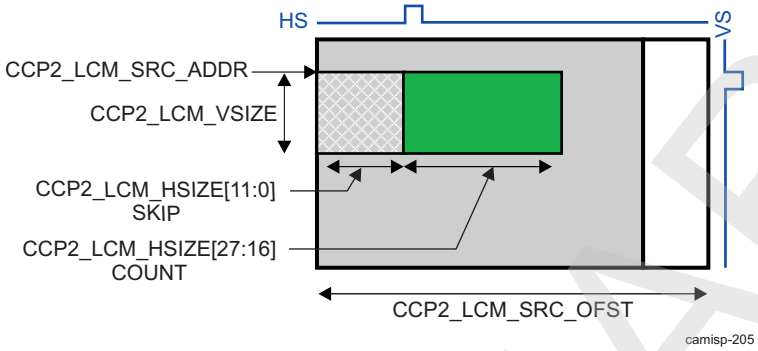
6.4.2.2.5.1 Camera ISP CSI1/CCP2B Read Data From Memory

Figure 6-62 shows the data organization in memory.

Figure 6-62. Camera ISP CSI1/CCP2B Data Organization in Memory



The user chooses the start address and the line length using the CCP2_LCM_SRC_ADDR and CCP2_LCM_SRC_OFST registers. The image start address normally must point to the beginning of a line because of packing constraints. However it does not necessarily point to the first line of the frame in memory. The CCP2_LCM_VSIZE [27:16] COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count (CCP2_LCM_HSIZE [11:0] SKIP) from the start of the line. However, they are not sent to the video port or back to memory. The CCP2_LCM_HSIZE [27:16] COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

When data are sent to the video port, throughput is imposed by the selected video port clock. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the CCP2_LCM_CTRL [4:3] READ_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the Video processing hardware.

The data storage format in memory is defined by the CCP2_LCM_CTRL [18:16] SRC_FORMAT, and CCP2_LCM_CTRL [23] SRC_PACK registers.

Not all IO format combinations are valid. See Table 6-24 and Table 6-25 for more information.

Figure 6-63 shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a,b,c). Therefore, data storage is little endian.

Figure 6-63. Camera ISP CSI1/CCP2B Data Organization in Memory Continued

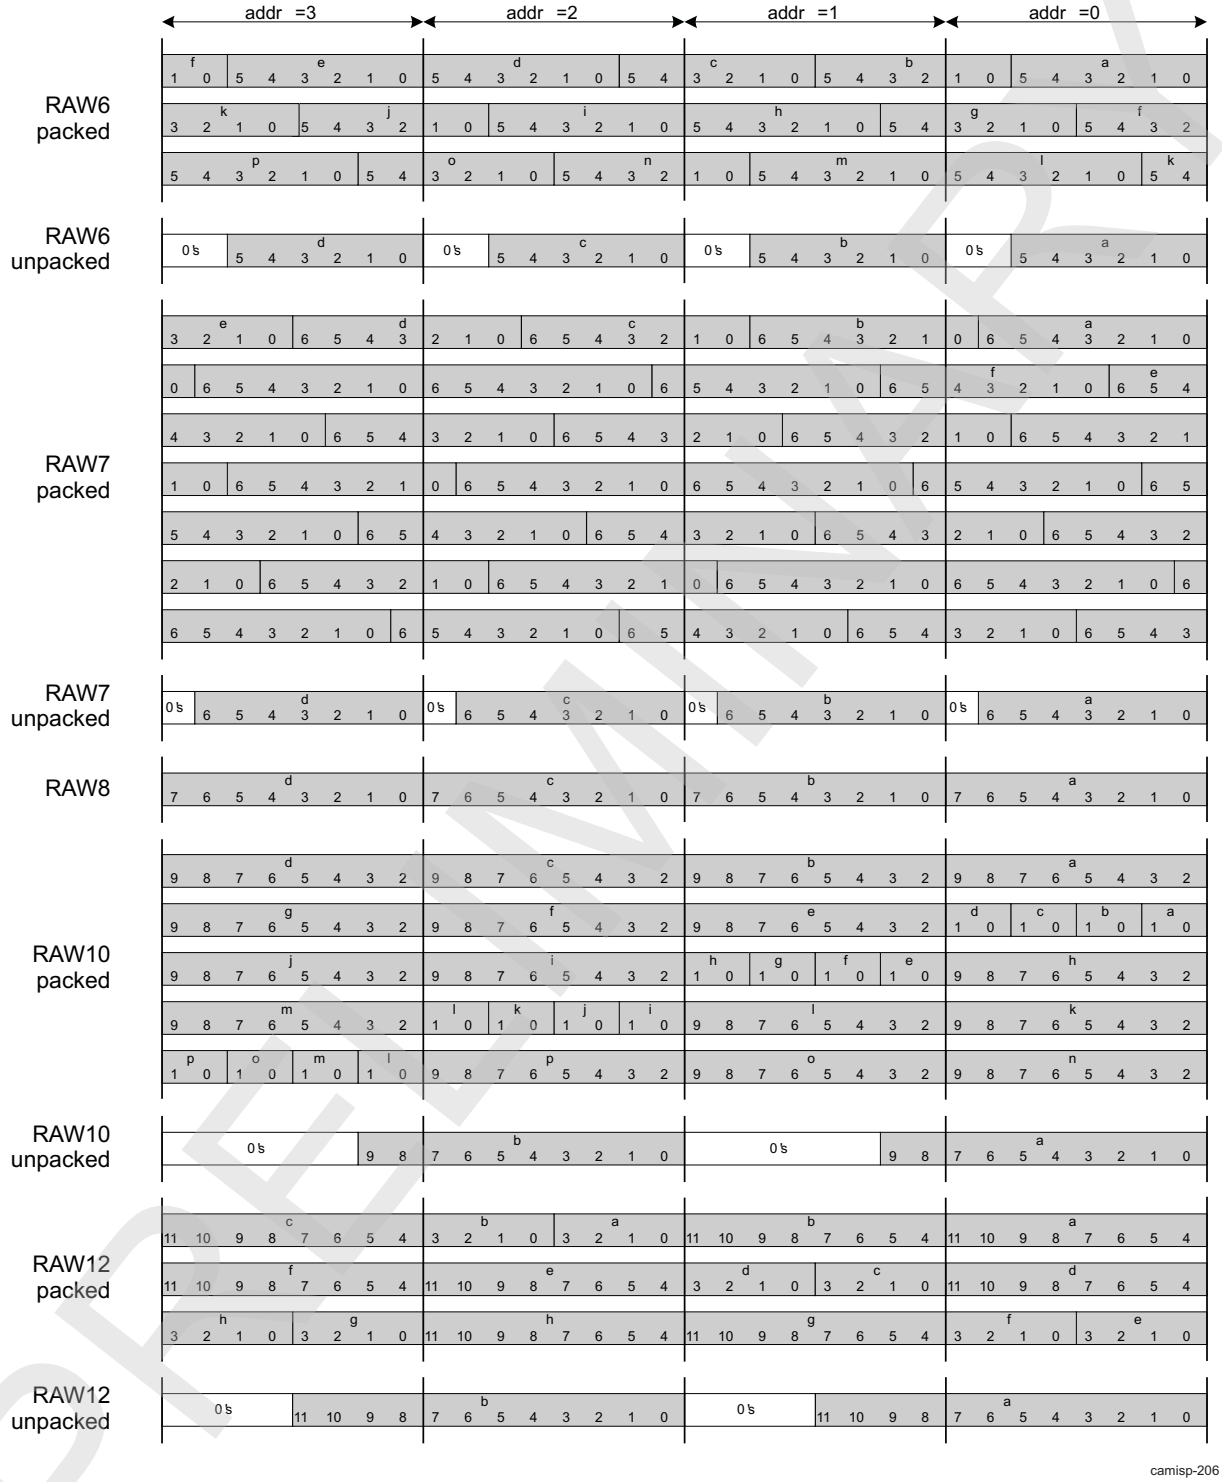


Table 6-26 summarizes the storage reduction and image width restrictions when data packing is used.

Table 6-26. Camera ISP CSI1/CCP2B Data Packing Benefit and Constraints

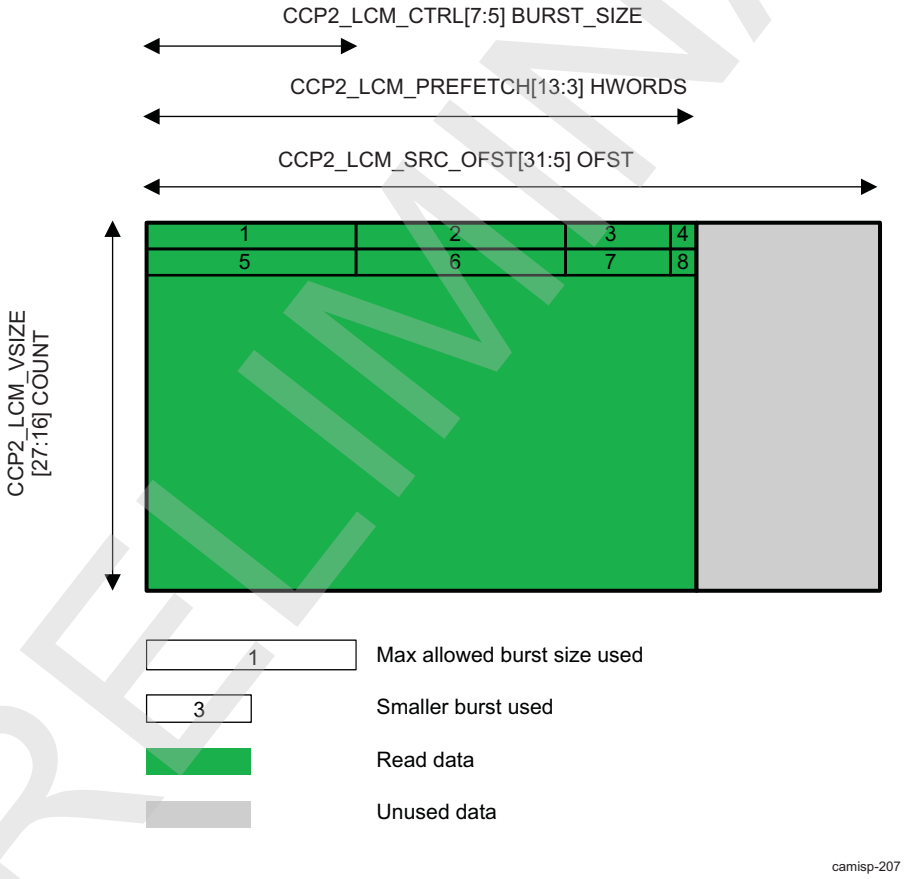
	Bits Per Pixel		Storage Reduction	Width Multiple [1]
	Packed	Unpacked		
RAW6	6	8	25%	16
RAW7	7	8	13%	32
RAW8	8	8	0%	4
RAW10	10	16	38%	16
RAW12	12	16	25%	8

(1) In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

6.4.2.2.5.2 Camera ISP CSI1/CCP2B Memory Read Port Burst Generation

The hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2B receiver. Only full 64-bit words are read. Figure 6-64 shows the data organization in memory.

Figure 6-64. Camera ISP CSI1/CCP2B Data Organization in Memory 3



NOTE:

- A minimum burst size of 2 must be selected for correct operation.
- HWORDS must be pair for correct operation.

Figure 6-63 shows the relationship between the different parameters controlling the burst generation. The

CCP2_LCM_SRC_ADDR register address of the first data to read is aligned to a 32-byte boundary. The read port fetches CCP2_LCM_PREFETCH [13:3] HWORDS of 64-bit words per line using the longest possible burst computed from the CCP2_LCM_CTRL [7:5] BURST register and the remaining data to be fetched. When the CCP2B receiver is configured to fetch more data than required, extra data are dropped internally.

6.4.2.2.5.3 Camera ISP CSI1/CCP2B Video Port

The video port always receives unpacked data. It can be enabled using the CCP2_LCM_CTRL [2] DST_PORT register. Its clock can be selected with the CCP2_CTRL [9:8] VP_OUT_CTRL register.

The data format used by the video port is defined by the CCP2_LCM_CTRL [26:24] DST_FORMAT register. See Table 6-25 for a list of supported modes.

6.4.2.2.5.4 Camera ISP CSI1/CCP2B Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the CCP2_LCM_CTRL [2] DST_PORT register. The output data format is defined by the CCP2_LCM_CTRL [26:24] DST_FORMAT, and CCP2_LCM_CTRL [31] DST_PACK registers. Not all possible combinations are supported. SeeTable 6-24 for details.

The destination address and offset for the output data of the memory channel are set by the CCP2_LCM_DST_ADDR and CCP2_LCM_DST_OFST registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in Table 6-27 apply.

Table 6-27. Camera ISP CSI1/CCP2B Output Width Restrictions in Memory-to-Memory Operation

Format	Bits/pix	Width Multiple of (1)	Note
RAW6	8	1	Full 32-bit words are written at the end of the line. This last word can eventually include 0s.
RAW6 PACK	6	1	
RAW7	8	1	
RAW7 PACK	7	1	
RAW8	8	1	
RAW10	16	1	
RAW10 PACK	10	16	
RAW12	16	1	Same constraints as RAW8
RAW12 PACK	12	8	

(1) In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see Figure 6-63).

When the DST_OFST is set to 0, start of lines will be aligned on 4-byte boundaries. When DST_OFST ! = 0, data are aligned on 32-byte boundaries.

NOTE: The RAW6 and RAW7 data formats do not apply to the MIPI® CSI1 compatible mode.

6.4.2.2.6 Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

The CCP2B receiver interface has several image-data operating modes, summarized in Table 6-28. The "EXPx" formats (x= 8, 16 or 32) are used to expand data up to 8, 16 or 32bits by padding data with 0's. The "Storage Increase Versus Packed" column indicates memory overhead versus format without data expansion or/and DPCM compression.

Table 6-28. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data size increase in memory. When negative, data compression present.	2D Mode Availability (1)	Comments
0x0	YUV422 big endian	16	0%	Yes

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data size increase in memory. When negative, data compression present.	2D Mode Availability (1)	Comments
0x1D	JPEG, 8-bit data + FSP	N/A	0%	Yes	
0x1E	RAW10 -> RAW8 DPCM	8	-20%	Yes	Data right shift
0x1F	RAW8 DPCM12-> RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x20	RAW10 -> RAW8 ALAW	8	-20%	Yes	
0x21	RAW8 DPCM10 -> ALAW	8	-20%	Yes	

NOTE:

- Padding data of a 32 bit pixel data stream is handled the same way regardless of the programmed format. Therefore, no storage increade/decrease because it is not compressed/decompressed.
- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros
  CCP2_LCx_CTRL[15:8] ALPHA can be used to set an alpha value.
  For RGB444 + EXP16:
  - data_out[31:28] = ALPHA [3:0]
  - data_out[15:12] = ALPHA [3:0]
- EXP32 = Data expansion to 32 bits, padding with alpha
  CCP2_LCx_CTRL[15:8] ALPHA can be used to set an alpha value.
  For RGB888 + EXP32: data_out [31:24] = ALPHA [7:0]
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video-preprocessing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
- DPCM10 = Data decompression to 10 bits. Only applies to the RAW6, RAW7 and RAW8 data formats. Disabled if CCP2_CTRL[4] MODE = 0.
- Padding is handled the same way regardless of the programmed format

6.4.3 Camera ISP CSI2 Receiver

NOTE: There are two CSI2 receiver in the ISP with same functionality. For reading ease, the following section will apply for both CSI2A and CSI2C receivers.

6.4.3.1 Camera ISP CSI2 Receiver Features

The CSI2 receiver module is a master on the L3 interconnect for storing data in memory and a slave on the L4 interconnect for register access.

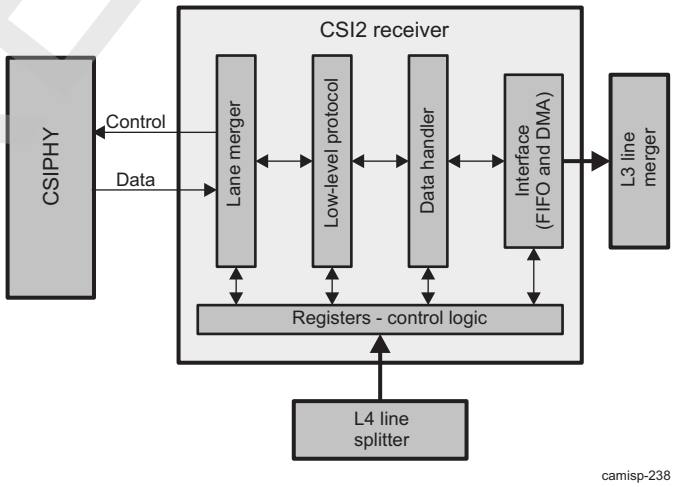
The main features of the CSI2 receiver module are:

- Transfer pixels and data received by the PHY to the system memory
- Unidirectional data link
- Minimum of one and maximum of two configurable data links in addition to clock signaling
- Maximum data rate of 1000 Mbps per data pair
- Data merger for 2-data lane configuration
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- Streaming 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- All primary and secondary MIPI®-defined formats are supported (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion of the RGB formats
- Decompression of the RAW formats
- RAW frame transcoding. Including DPCM and A-law compression
- Configuration of PHY
- Fully configurable interface of the PHY: position of the clock and data and order of +/- differential signals for each pair
- Support of DPCM decompression

6.4.3.2 Camera ISP CSI2 Receiver Block Diagram

Figure 6-65 is the block diagram of the CSI2 receiver connected to the PHY.

Figure 6-65. Camera ISP CSI2 Receiver Block Diagram



6.4.3.3 Camera ISP CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer. The CSI2 PHY is based on the MIPI® DPHY Specification version 1.0.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of four to six signals: one or two data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the DDR clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 PHY receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or a clock lane. The clock/data lane must be configured before transmission to indicate the byte order while merging the received bytes into a byte stream.

Lanes are configured through the CSI2_COMPLEXIO_CFG1 register for the associated and configured to the receiver PHY. The CLOCK_POSITION and CLOCK_POL fields configure which lane transmits the clock and define its polarity.

NOTE: If the parallel camera sensor and other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding CSI2_COMPLEXIO_CFG1.DATAx_POSITION bit must be set to 0x0 for the lane used in GPI mode.

The CSI2_COMPLEXIO_CFG1 register also contain a bit field affecting PHY power management.

For information about initializing the CSIPHY associated with CSI2, see Section 6.5.2.2, *Camera ISP CSIPHY Initialization for Work With CSI2 Receiver*.

6.4.3.4 Camera ISP CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

6.4.3.4.1 Camera ISP CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bit stream. If the ECC does not match, an interrupt is triggered to the host CPU.

For both long and short packets, the correction is always done if there is only one error per packet.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. Table 6-29 describes the field where events are logged. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_IRQENABLE and CSI2_CTx_IRQENABLE registers to prevent event generation at a higher level.

Table 6-29. Camera ISP CSI2 ECC Event Logging

	Short Packet	Long Packet
With correction	Global CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	Context CSI2_CTx_IRQSTATUS[8] ECC_CORRECTION_IRQ

Table 6-29. Camera ISP CSI2 ECC Event Logging (continued)

	Short Packet	Long Packet
Without correction	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	Global CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by writing 0 in the CSI2_CTRL[2] ECC_EN bit field. Writing 1 enables the ECC check.

6.4.3.4.2 Camera ISP CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an event is triggered to the host CPU.

CRC errors are logged in the CS_IRQ field of the corresponding context register, CSI2_CTx_IRQSTATUS. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_CTx_IRQENABLE register to prevent event generation at a higher level.

The CRC check can be disabled for a specific context by writing 0 in the CSI2_CTx_CTRL1[5] CS_EN bit. Writing 1 enables the CRC check.

6.4.3.5 Camera ISP CSI2 RAW Image Transcoding with DPCM and A-law Compression

The CSI2 receiver has a funtionality to have an image in raw format transcoded. Transcoding is mainly used to reduce memory footprint and bandwith when:

- The sensor does not support DPCM compression. So by transcoding A-law and DPCM compressed pixels only occupy 6, 7 or 8-bits/pixel of storage.
- Digital zoom is used. In fact:
  - Data that is not going to be used by further processing does not need to the stored in system memory.
  - Pixels can't be accessed from random locations in a DPCM compressed frame. So, Transcoding avoids memory to memory processing of unused pixels.

Figure 6-66 shows the logical representation of the image transcoding operation. Basically, the steps are as follow:

- Data is extracted from the CSI2 stream
- It is DPCM decompressed if necessary. That's the case when the received stream is DPCM compressed and transcoding has been enabled using the CSI2_CTx_CTRL1[27:24] TRANSCODE register.
- Data send to the video port can not be compressed: it is intended to be processed by an HW ISP. Data send to system memory could be optionally compressed.
- Internal data is aligned on MSB when the enter the cropping stage:
  - 4 LSBs are 0s when RAW10 data is handled
  - 2 LSBs are 0s when RAW12 data is handled
  - etc...

Figure 6-66. Camera ISP CSI2 RAW Image Transcoding Diagram

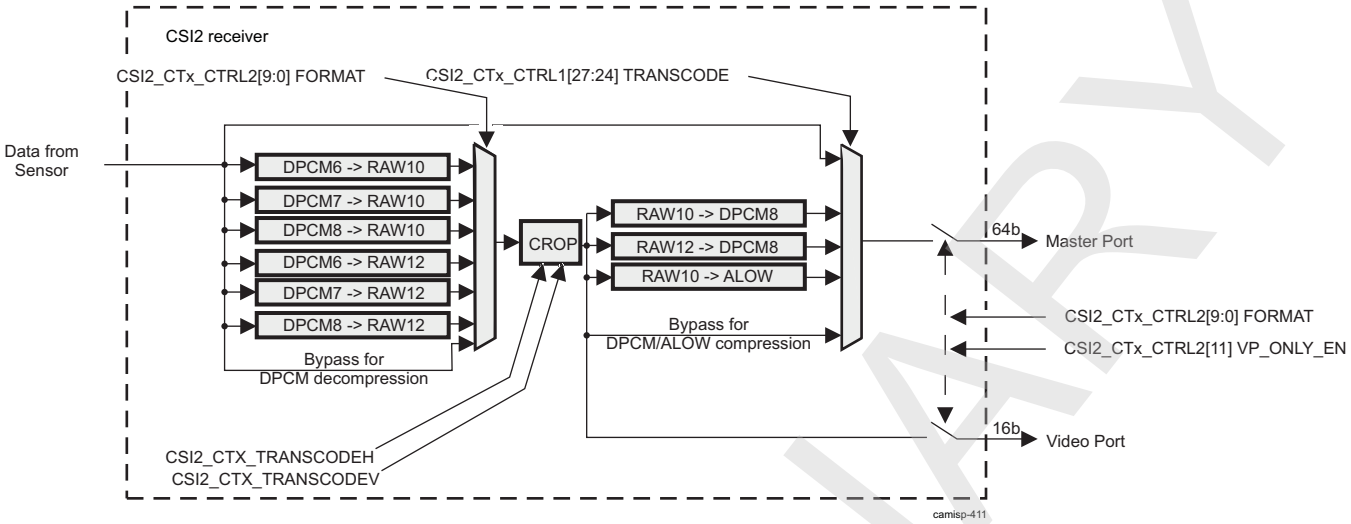


Table 6-30 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the table below are not supported for transcoding.

Table 6-30. Camera ISP Pixel Format Modes

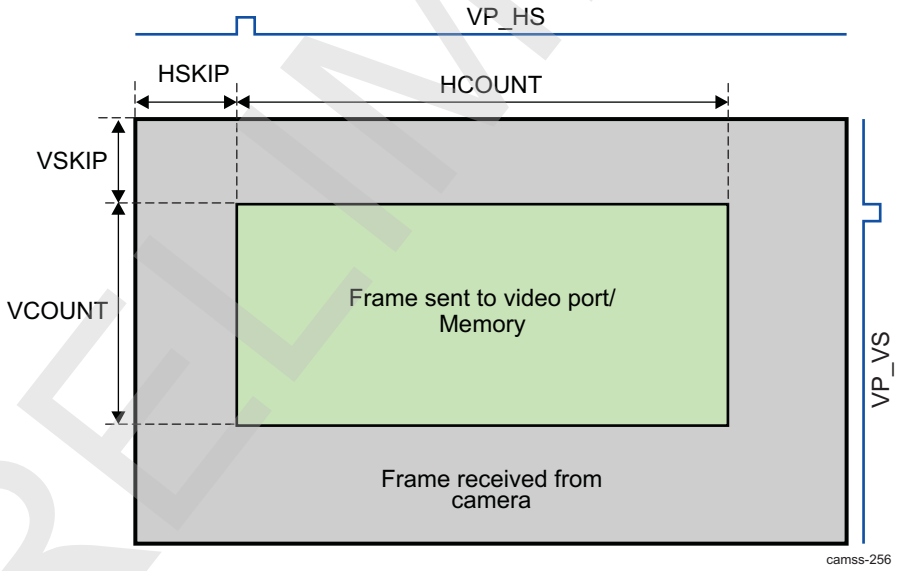
CSI2_CTx_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x028	RAW6	RAW6		
0x068	RAW6 + EXP8			
0x029	RAW7	RAW7		
0x069	RAW7 + EXP8			
0x02A	RAW8	RAW8		
0x12A	RAW8 + VP			Yes
0x02B	RAW10	RAW10		
0x0AB	RAW10 + EXP16			
0x0E8	RAW6 + DPCM10 + VP		Yes	Yes
0x12F	RAW10 + VP			Yes
0x229	RAW7 + DPCM10 + EXP16		Yes	
0x2A8	RAW6 + DPCM10 + EXP16		Yes	
0x2AA	RAW8 + DPCM10 + EXP16		Yes	
0x329	RAW7 + DPCM10 + VP		Yes	Yes
0x32A	RAW8 + DPCM10 + VP		Yes	Yes
0x2Cn	USER_DEFINED_BYTE_DATA + DPCM10 + EXP16		Yes	
0x34n	USER_DEFINED_BYTE_DATA + DPCM10 + VP		Yes	Yes

Table 6-30. Camera ISP Pixel Format Modes (continued)

CSI2_CTx_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x02C	RAW12	RAW12		
0x0AC	RAW12 + EXP16			
0x12C	RAW12 + VP			
0x36A	RAW8 + DPCM12 + EXP16		Yes	
0x3AA	RAW8 + DPCM12 + VP		Yes	Yes
0x1Cn	USER_DEFINED_BYTE_DATA + DPCM12 + EXP16		Yes	
0x14n	USER_DEFINED_BYTE_DATA + DPCM12 + VP		Yes	
0x3A8	RAW6 + DPCM12 + EXP16		Yes	
0x368	RAW6 + DPCM12 + VP		Yes	Yes
0x369	RAW7 + DPCM12 + EXP16		Yes	
0x3A9	RAW7 + DPCM12 + VP		Yes	Yes
0x02D	RAW14	RAW14		
0x0AD	RAW14 + EXP16			
0x12D	RAW14 + VP			Yes

Image cropping parameters are controlled by software. Figure 6-67 provides a graphical representation of the cropping operation.

Figure 6-67. Camera ISP CSI2 Frame Cropping



NOTE: Hardware doesn't check for validity of the settings. The following rules must be respected:

- CSI2_CTx_TRANSCODEH[12:0] HSKIP+ CSI2_CTx_TRANSCODEH[28:16] HCOUNT <= image width
- CSI2_CTx_TRANSCODEV[12:0] VSKIP+ CSI2_CTx_TRANSCODEV[28:16] VCOUNT <= image height

Furthermore, CSI2_CTx_TRANSCODEV[28:16] HCOUNT must comply with the following alignment constraints. Undefined behavior occurs otherwise. Table 6-31 shows the ranscode alignment constraints

Table 6-31. Camera ISP CSI2 Transcode Alignment Constraints

CSI2_CTx_CTRL[27:24] TRANSCODE value	Transcode	HCOUNT must be multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

Table 6-32 shows the possible combinations between input and output formats supported by the transcoding engine. The "TRANSCODE" column corresponds to the CSI2_CTx_CTRL1[27:24] TRANSCODE register of a context.

Table 6-32. Camera ISP CSI2 Supported Transcoding Output Formats

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
RAW6	0	Disabled	Yes	RAW10	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	Yes
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	Yes
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	Yes
	6	RAW10			6	RAW10	Yes
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14			9	RAW14	
RAW7	0	Disabled	Yes	RAW12	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	Yes
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	Yes
	8	RAW12			8	RAW12	Yes
	9	RAW14			9	RAW14	
RAW8	0	Disabled	Yes	RAW14	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8	Yes		4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14			9	RAW14	Yes

For RAW10 and RAW12, Software could choose among packed and non packed storage. A-law and DPCM compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point. Similarly, RAW data is send over the video port . Enabling of the OCP / video port is controlled as usual by the CSI2_CTx_CTRL2[9:0] FORMAT and CSI2_CTRL[11] VP_ONLY_EN and CSI2_CTx_CTRL1[2] VPFORCE registers.

In order to enable transcoding, The software configures the context normally and in addition, configures the framing using the CSI2_CTx_TRANSCODEV and CSI2_CTx_TRANSCODEH registers. The software defines the after transcoding with the CSI2_CTx_CTRL1[27:24] TRANSCODE register.

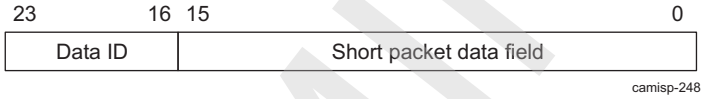
6.4.3.6 Camera ISP CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled (see Section 6.4.3.4.1, *ECC*). Then, the short packet is written in the CSI2_SHORT_PACKET[23:0] SHORT_PACKET bit field. The ECC field is deleted from the short packet. Figure 6-68 shows the SHORT_PACKET field format.

Figure 6-68. Camera ISP CSI2 SHORT_PACKET Field Format



An event is logged when a short packet is stored in the SHORT_PACKET_IRQ bit in the CSI2_IRQSTATUS[13] register. Logging cannot be disabled, but users can set the corresponding bit in the CSI2_IRQENABLE register to prevent event generation at a higher level.

The application reads the CSI2_SHORT_PACKET register before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

6.4.3.7 Camera ISP CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

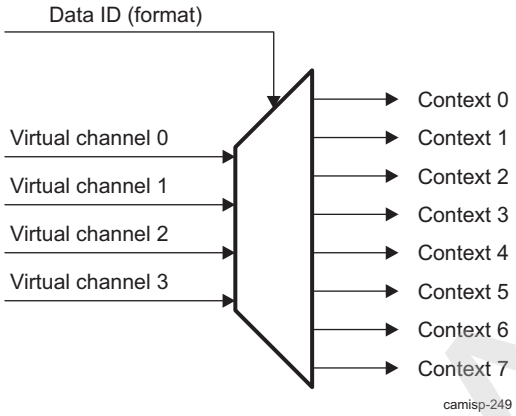
The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following two bit fields permit configuration of a context:

- CSI2_CTx_CTRL2[12:11] VIRTUAL_ID: Configures the virtual ID linked to the current context
- CSI2_CTx_CTRL2[9:0] FORMAT: Configures the data format linked to the current context

Figure 6-69 shows the relationships between virtual channels and contexts.

Figure 6-69. Camera ISP CSI2 Virtual Channel to Context



Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by writing 1 in the CSI2_CTx_CTRL1[0] CTX_EN bit field; writing 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the CSI2_CTx_CTRL1[15:8] COUNT bit field. Acceptable values are 0:255; 0 stands for infinite capture (no count). After each frame acquired, the count value is decremented by 1. When the count value reaches 0, the CSI2_CTx_IRQSTATUS[6] FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the CSI2_CTx_CTRL1[4] COUNT_UNLOCK bit must be set to 1. If the COUNT_UNLOCK value is 0, a write in the COUNT bit field has no effect.

The CSI2_CTx_CTRL3[15:0] LINE_NUMBER bit field configures the generation of the CSI2_CTx_IRQSTATUS[7] LINE_NUMBER_IRQ event. The CSI2_CTx_CTRL1[1] LINE_MODULO bit configures how the LINE_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the CSI2_CTx_CTRL2[31:16] FRAME_NUMBER bit field shows the number that identifies the frame received.

6.4.3.8 Camera ISP CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration (single access, non-streaming and posted writes) is common to the eight channels and is defined in the CSI2_CTRL register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports the following requests:

- Single write

When an element (the size depends on the data type) is present in the FIFO, the DMA engine initiates a single write.

All single requests sent to the interconnect are back-to-back requests with no idle, if the FIFO has enough data to supply the DMA.

The DMA starts to write in memory using the CSI2_CTx_DAT_PING_ADDR[31:5] ADDR bit field for the first frame to be transferred and then uses the CSI2_CTx_DAT_PONG_ADDR[31:5] ADDR bit field and the ping address alternately. So, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The CSI2_CTx_CTRL1[3] PING_PONG status bit indicates whether the ping address (CSI2_CTx_DAT_PING_ADDR) or the pong address (CSI2_CTx_DAT_PONG_ADDR) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the CSI2_CTRL[0] IF_EN register, the pixel data is written in the ping buffer and CSI2_CTx_CTRL1[3] PING_PONG = PONG. When the number of FECs received equals the value programmed in the CSI2_CTx_CTRL1[23:16] FEC_NUMBER bit field, the pixel data are written in the pong buffer and CSI2_CTx_CTRL1[3] PING_PONG = PING. CSI2_CTx_CTRL1[3] PING_PONG toggles after the CSI2_CTx_CTRL1[23:16] FEC_NUMBER FEC sync code with the virtual channel ID defined is received in the CSI2_CTx_CTRL2[12:11] VIRTUAL_ID bit field.

The CSI2_CTx_CTRL1[23:16] FEC_NUMBER bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the PING_PONG buffer.

6.4.3.8.1 Camera ISP CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the CSI2_CTx_DAT_OFST[15:5] OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the OFST value sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTx_DAT_PING_ADDR @Line1 = @Line0 + CSI2_CTx_DAT_OFST
@Line2 = @Line1 + CSI2_CTx_DAT_OFST
```

For the pong frame:

```
@Line0 = CSI2_CTx_DAT_PONG_ADDR @Line1 = @Line0 + CSI2_CTx_DAT_OFST
@Line2 = @Line1 + CSI2_CTx_DAT_OFST
```

6.4.3.8.2 Camera ISP CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

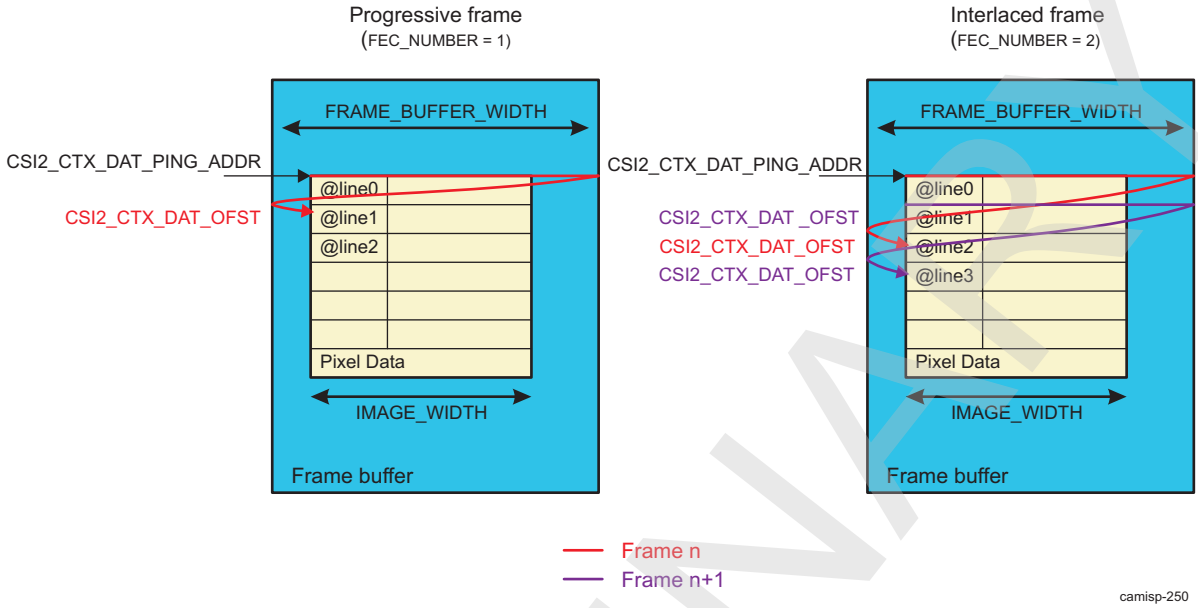
```
@LineX = CSI2_CTx_DAT_PING_ADDR + CSI2_CTx_DAT_OFST * Line_Number
```

For the pong frame:

```
@LineX = CSI2_CTx_DAT_PONG_ADDR + CSI2_CTx_DAT_OFST * Line_Number
```

Figure 6-70 shows how data are stored in memory regarding DMA configuration.

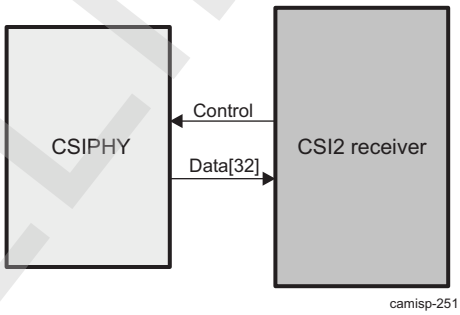
Figure 6-70. Camera ISP CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode



6.4.3.9 Camera ISP CSI2 PHYs

The two PHYs in the device act as the interface between the transmitter (camera sensor) and the receivers inside the camera ISP. The modules transform the bit stream divided into one or two serial data lanes into a bit stream compatible with the CSI2 receiver and one clock lane. The two CSIPHY1 and CSIPHY2 have identical functionality, only difference is that CSIPHY1 is limited to one data line. Figure 6-71 shows the CSIPHY overview diagram.

Figure 6-71. Camera ISP CSI2 PHY Overview



The CSI2_COMPLEXIO1_IRQSTATUS register logs the CSIPHY event. The events that occur are:

- Line power state change (all lanes in ULPM, at least one lane exits ULPM, etc.)
- Error on one lane

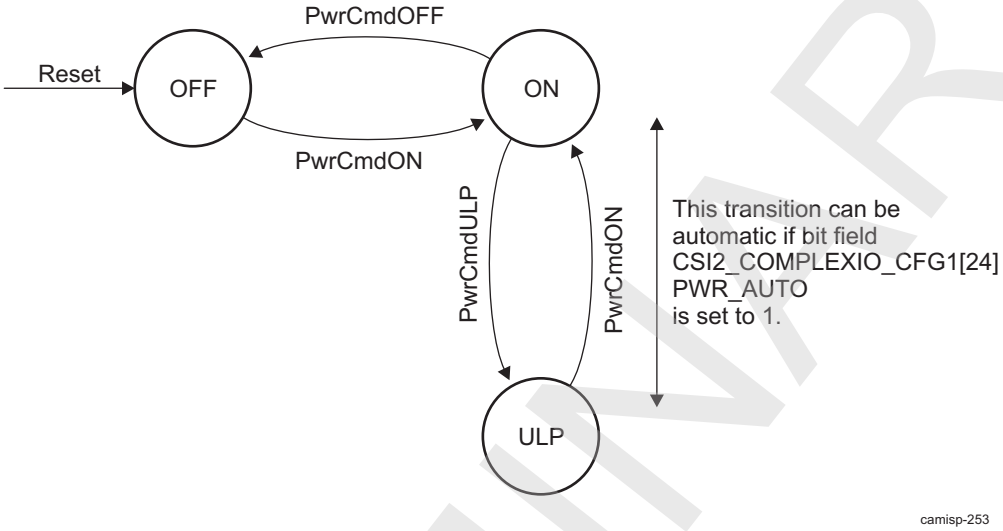
NOTE: For information about initializing the CSIPHY associated with CSI2, see Section 6.5.2.2, *Camera ISP CSIPHY Initialization for Work With CSI2 Receiver*.

Both CSI2A and CSI2C receivers embed a registers to configure/read some PHY parameters:

- The CSI2_COMPLEXIO_CFG1 register reports completion of reset on the different parts of the module and configures timing parameters.

The CSIPHY's have three power modes: on, off, and ULP (ultra-low power). These modes can reflect the ON or ULP power state of the three differential lines if the CSI2_COMPLEXIO_CFG1[24] PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the PHY power state is controlled by the CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD bit field, which directly defines the power state. Figure 6-72 shows the PHY power finite state machine (FSM).

Figure 6-72. Camera ISP CSIPHY Power FSM



Another register, CSI2_TIMING, is used to control the power state of the CSIPHY module with regards to the differential line state. This register is used to control the mode of the CSIPHY (RxMode or NoRxMode) and the delay between all the differential lines on STOP state and CSIPHY on NoRxMode. The CSI2_TIMING[15] FORCE_RX_MODE_IO1 bit field sets the CSIPHY in RxMode or in NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bit fields (CSI2_TIMING[14] STOP_STATE_X16_IO1, CSI2_TIMING[13] STOP_STATE_X4_IO1, and CSI2_TIMING[12:0] STOP_STATE_COUNTER_IO1) configure the delay between line stop mode and CSIPHY stop mode. The delay represents the number of functional clock (CAM_FCLK) cycles and can be calculated as follows:

Total delay in CAM_FCLK cycle = CSI2_TIMING.STOP_STATE_COUNTER_IO1 x (1 + CSI2_TIMING.STOP_STATE_X16_IO1 x15) x (1 + CSI2_TIMING.STOP_STATE_X4_IO1 x 3).

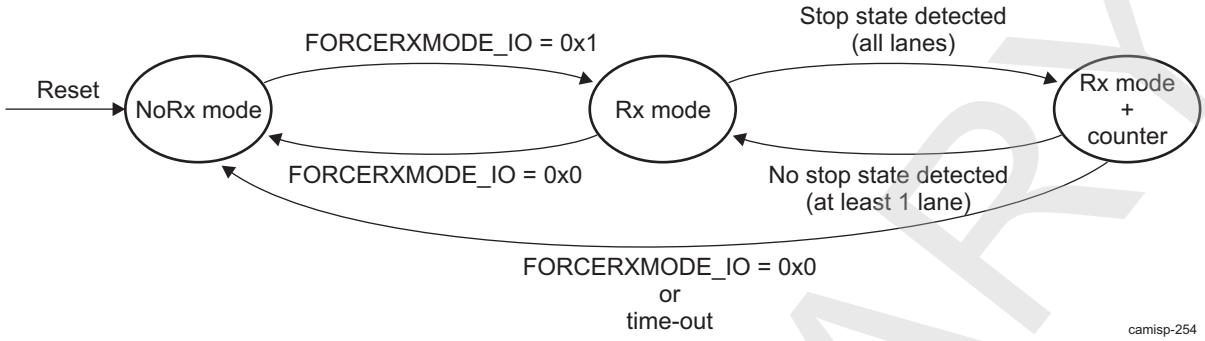
Table 6-33 lists the possible values of the delay, in terms of the CAM_FCLK cycles, depending on the values of the STOP_STATE_X16_IO1 and STOP_STATE_X4_IO1 bits.

Table 6-33. Camera ISP CSI2 Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (In Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The state-machine controlling the RxMode is presented in Figure 6-73.

Figure 6-73. Camera ISP CSI2 RxMode and StopState FSM



6.4.3.10 Camera ISP CSI2 Data Decompression

The data compression technique used is differential pulse code modulation (DPCM) and pulse code modulation (PCM).

The CSI2 receiver performs on-the-fly decompression. The decompressed data is either passed to the Video processing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded/decoded separately.

There are two different predictors used:

- The simple predictor

  This predictor uses only the previous same color component value as a prediction value. Therefore, only two-pixel memory is required.
- The advanced predictor

  This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value has been defined.

The preferable usage is that simple predictor is used with 10 bits to 8 bits conversion (10 8 10) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10 7- 10 and 10 6 10). The advanced predictor gives slightly better prediction for pixel value and so the image quality can be improved with it. The simple predictor is very simple and so the processing power and the memory requirements are reduced with it, when the image quality anyway is high enough.

To select DPCM decompression predictor for CSI2 Interface, set the CSI2_CTx_CTRL2[10] DPCM_PRED to 1 for simple predictor or to 0 for advanced predictor.

6.4.3.11 Camera ISP CSI2 EndOfFrame and EndOfLine pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line. Software can enable/disable generation of those signals for each context using the CSI2_CTx_CTRL1[7] EOF_EN and CSI2_CTx_CTRL1[6] EOL_EN registers.

6.4.4 Camera ISP Timing Control

6.4.4.1 Camera ISP Timing Control Features

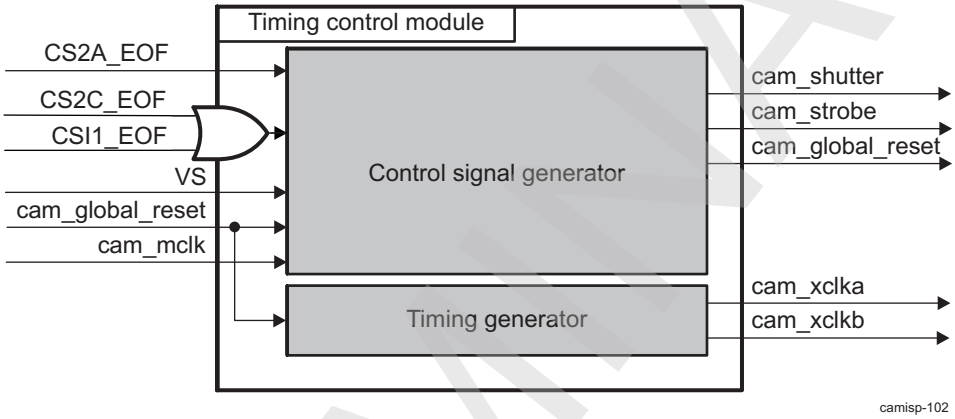
The timing-control module provides two clocks (cam_xclka and cam_xclkb) that can be used by external camera modules. It also generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

6.4.4.2 Camera ISP Timing Control Overview

Figure 6-74 shows a block diagram of the timing-control module.

Figure 6-74. Camera ISP Timing Control block diagram



6.4.4.2.1 Camera ISP Timing Control Generator

The timing coontrol generates the cam_xclka and cam_xclkb clocks based on the CAM_MCLK frequency, which can be up to 216 MHz. The cam_mclk is used only by the clock generator; the cam_xclka and cam_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

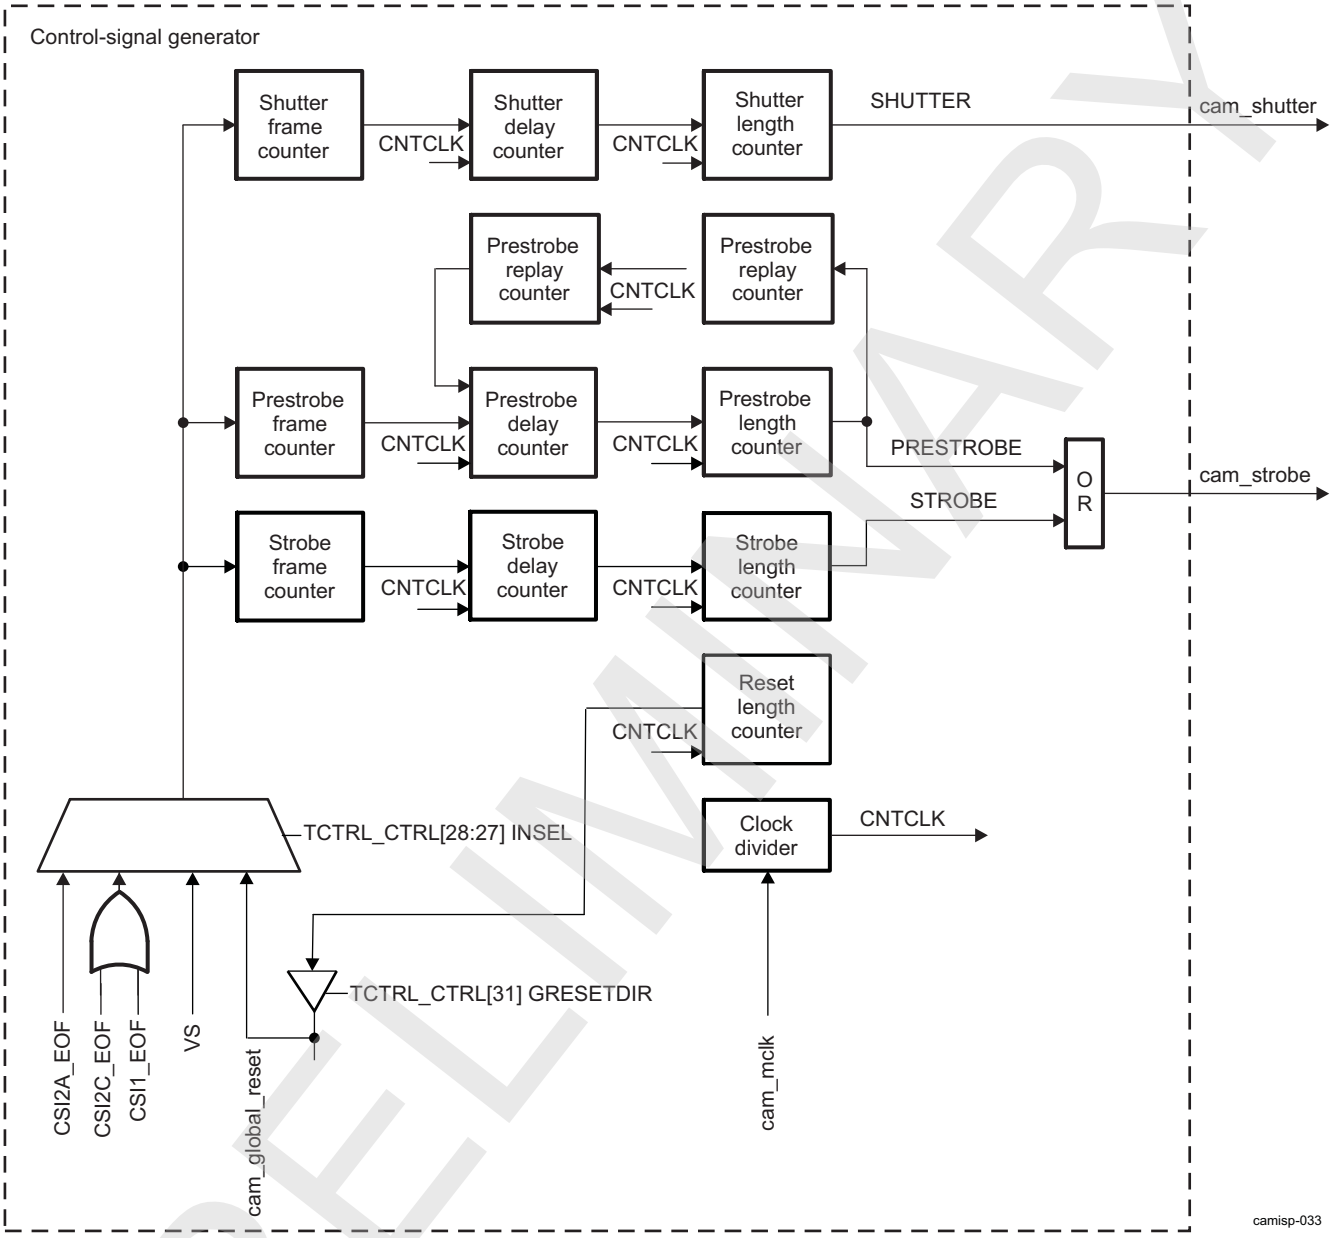
The possible frequencies of cam_xclka and cam_xclkb and their respective configurations are described in Section 6.3.1.1.3, *Clock Configuration*.

Table 6-34 summarizes the possible frequencies as a function of the divisor values.

6.4.4.2.2 Camera ISP Timing Control Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter. Figure 6-75 shows the principle of control-signal generation.

Figure 6-75. Camera ISP Timing Control Control-Signal Generation



The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the CSI2A (VP_VS from CSI2A), CSI2C (VP_VS from CSI2C), CSI1/CCP2B(VP_VS from CSI1/CCP2B),or PARALLEL interface (cam_vs), or on an externally-generated cam_global_reset signal.

A multiplexer controls which of the CSI2A, CSI1/CCP2B or CSI2C, and PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated cam_global_reset signal as the trigger event. The TCTRL_CTRL [31] GRESETDIR register defines the direction of the cam_global_reset signal.

- The external generated cam_global_reset is used as a trigger when TCTRL_CTRL [31] GRESETDIR = 0 and TCTRL_CTRL[27:28] INSEL = 3.
- The internally generated cam_global_reset is used as a trigger when TCTRL_CTRL [31] GRESETDIR = 1 and TCTRL_CTRL[27:28] INSEL = 3.
- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes

and on both output ports: video port and shared-buffer-logic (SBL) port.

- If the CSI2A or CSI1/CCP2B/CSI2C interface is selected, control-signal generation works on both output ports: video port and interconnect port.

The cam_global_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam_global_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_global_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam_mclk clock. The clock divider is programmable. Table 6-34 summarizes the possible frequencies as a function of the divisor values.

Table 6-34. Camera ISP Timing Control Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCDC or from receiver modules.
  - A new frame is detected in the CSI2A, CSI1/CCP2B, CSI2C receivers on detection of a frame-start code (FSC) followed by a frame-end code (FEC).
  - A new frame is detected in the CCDC module by using the falling edge of the vertical synchronization signal at the input of the CCDC module.

NOTE: The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCDC cannot be used. The modules have no effect on this detection.

  - The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

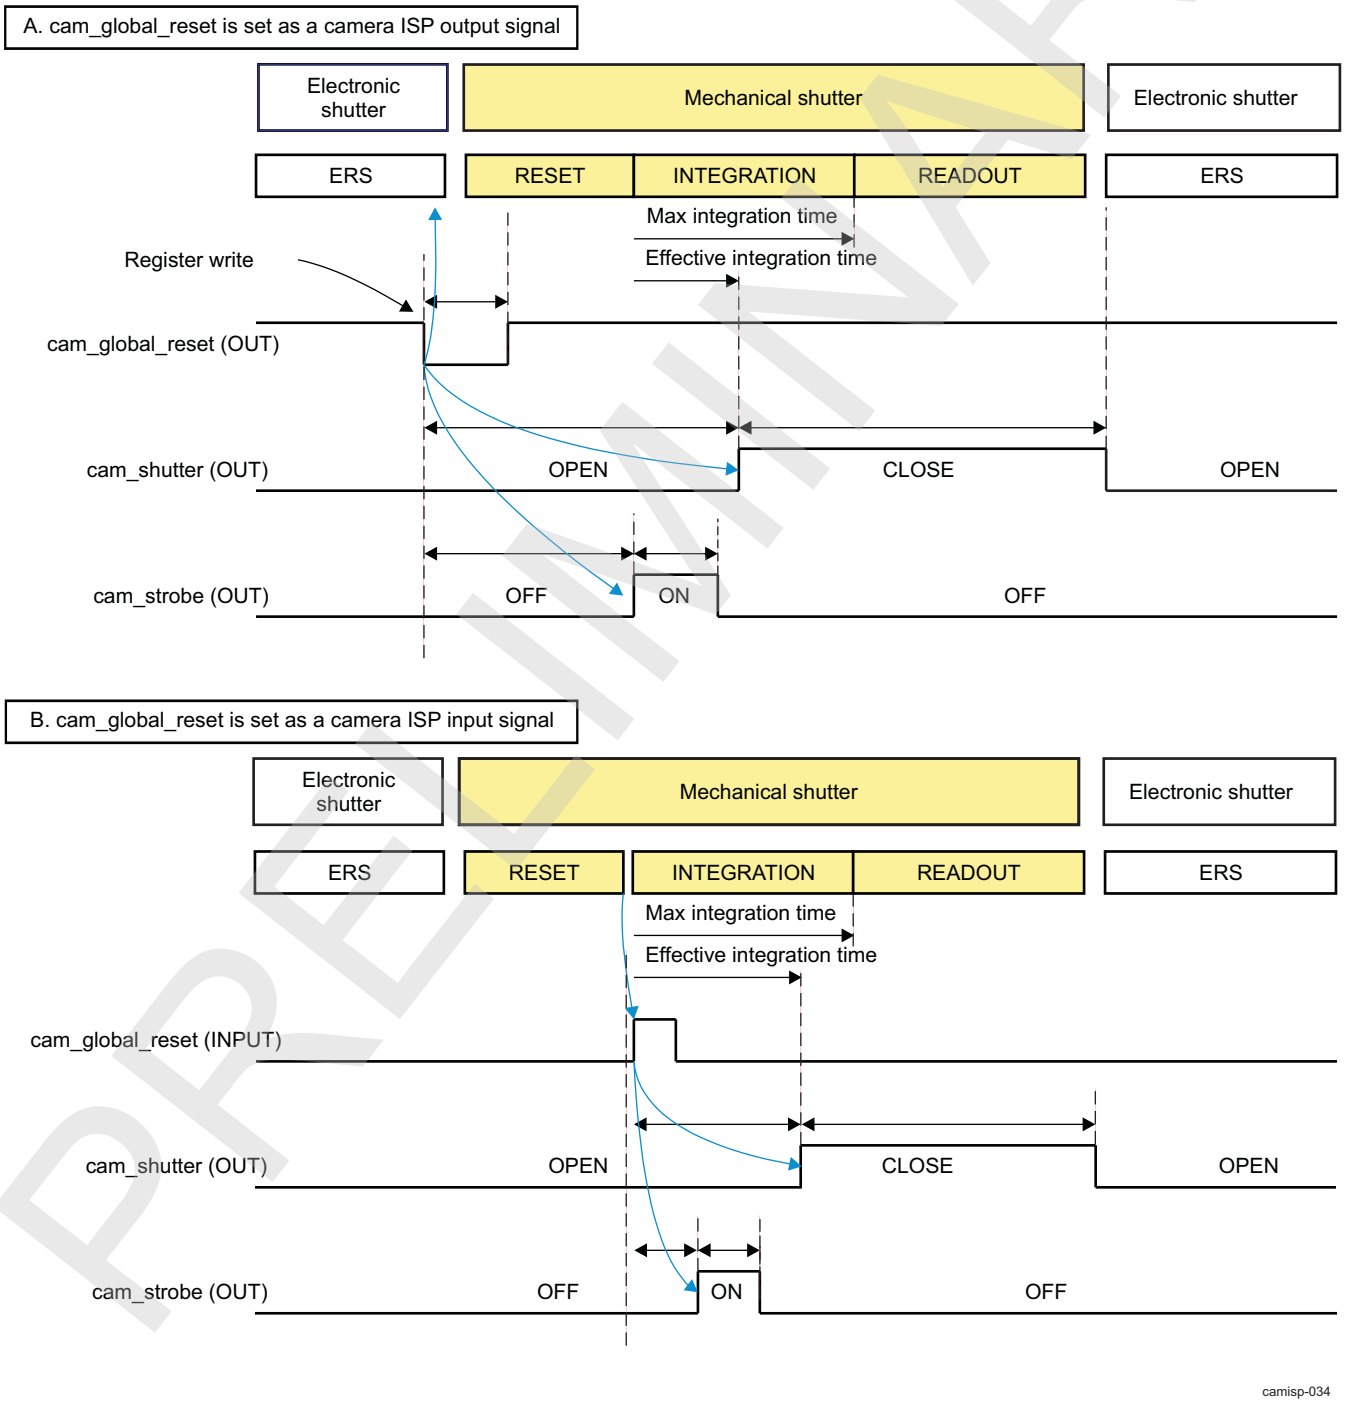
- TCTRL_CTRL [26] STRBPSTRBPOL for the prestrobe and strobe signals
- TCTRL_CTRL [24] SHUTPOL for the shutter signal
- TCTRL_CTRL [30] GRESETPOL for the cam_global_reset signal

The software can trigger the generation of the cam_global_reset signal to the camera module. The

signal-activation length is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (TCTRL_CTRL [29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the cam_global_reset signal can be selected (TCTRL_CTRL [30] GRESETPOL bit).

Figure 6-76 shows the use of the cam_global_reset signal set as an input or output signal. cam_global_reset is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle

Figure 6-76. Camera ISP Timing Control Use of cam_global_reset With Global Reset Release Camera Modules



There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam_global_reset, cam_shutter, and cam_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

Mechanical shutter mechanism:

- Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
- Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is defined by the time between reset release and shutter close.
- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.

Electronic rolling shutter mechanism (ERS):

- Each line of the sensor is reset separately and read after a fixed amount of time. Expose time is defined by the time between reset and read.

6.4.5 Camera ISP Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the ISP_CTRL [7:6] SHIFT register. Table 6-35 describes the different configurations.

Table 6-35. Camera ISP Bridge-Lane Shifter

Sensor	Connected to	Data Lane Shifter 0	Data Lane Shifter 1	Data Lane Shifter 2	Data Lane Shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
	[13:6]	14 bits	12 bits	10 bits	8 bits	CSI2 only
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
	[13:4]	14 bits	12 bits	10 bits	8 bits	CSI2 only
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	
	[13:2]	14 bits	12 bits	10 bits	8 bits	CSI2 only
14 bits	[13:0]	14 bits	12 bits	10 bits	8 bits	CSI2 only

Blue shading means that the data is too wide for the Video processing hardware: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the ISP_CTRL [3:2] PAR_BRIDGE register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
  - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
  - Some CCDC modules cannot work with the bridge. For details, see Figure 6-78.

6.4.6 Camera ISP Video-Processing Front End

The video-processing front end (VPFE) comprises the CCDC and the lens-shading compensation.

6.4.6.1 Camera ISP CCDC

6.4.6.1.1 Camera ISP CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

- **Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).
- **CCDC interface:** The camera ISP module interface comes either from the external parallel interface or from the output of the CSI2A, CSI2C, CSI1/CCP2B receivers (through the video-port interface). It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
  - Supports two synchronization modes:
    - **SYNC mode:** In this mode, the cam_hs and cam_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, 12-, and 14-bit data. It supports both progressive and interlaced image-sensor modules.

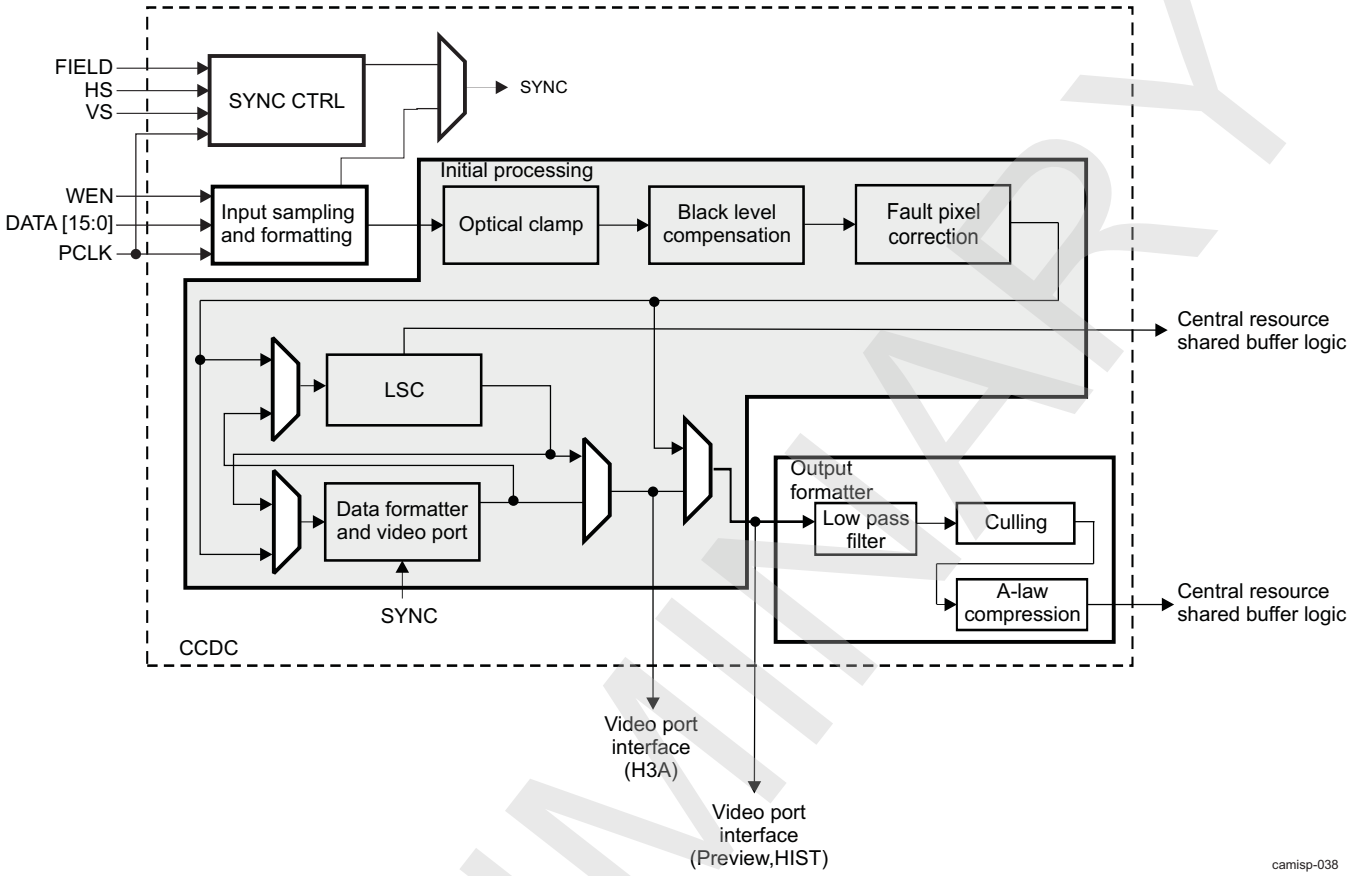
      NOTE: Input from CSI1/CCP2B is limited to 12 bits and input from CSI2 is limited to 14 bits

    - **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations.
- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
  - Optical clamp
  - Black-level compensation
  - Faulty-pixel correction
  - 2D map based lens-shading compensation (LSC)
  - Data formatter and video port
  - Output formatter and Culling
  - DC subtract
- **YUV data processing:** The output data can go directly to memory for software processing or to the Resizer module for further processing. The operations include:
  - Output formatter and Culling
  - DC subtract
- Memory ports: The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

6.4.6.1.2 Camera ISP CCDC Block Diagram

Figure 6-77 shows the top-level block diagram of the CCDC module.

Figure 6-77. Camera ISP CCDC Block Diagram



The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario. See Table 6-21 for ISP and CCDC allowed data flows.

For RAW8/10 data (CCDC_SYN_MODE [13:12] INPMODE = 0 && CCDC_REC656IF [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the computing statistics (H3A, histogram) modules for further processing.
- JPEG still image capture data is not processed by the internal CCDC modules. The data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data (CCDC_SYN_MODE [13:12] INPMODE = 1 or 2 && CCDC_REC656IF [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the Resizer module for upscaling or downscaling.

6.4.6.1.3 Camera ISP CCDC Functional Operations

6.4.6.1.3.1 Camera ISP CCDC SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

6.4.6.1.3.2 Camera ISP CCDC Input Sampling and Formatting

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through ISP_CTRL [4] PAR_CLK_POL.
- Data can be interpreted as normal or inverted (CCDC_SYN_MODE[6] DATAPOL).
- For RAW data:
  - Data is clipped to the number of LSBs specified in the CCDC_SYN_MODE [10:8] DATSIZ field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
  - The MSB of the chroma signal can also be inverted (CCDC_CFG [13] MSBINVI). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

6.4.6.1.3.3 Camera ISP CCDC Initial Processing

Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (CCDC_CLAMP [24:10] OBST) of each line (CCDC_CLAMP [30:28] OBSLEN) and for the number of indicated lines (CCDC_CLAMP [27:25] OBSLN), plus an optional gain adjustment (CCDC_CLAMP [4:0] OBGAIN), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

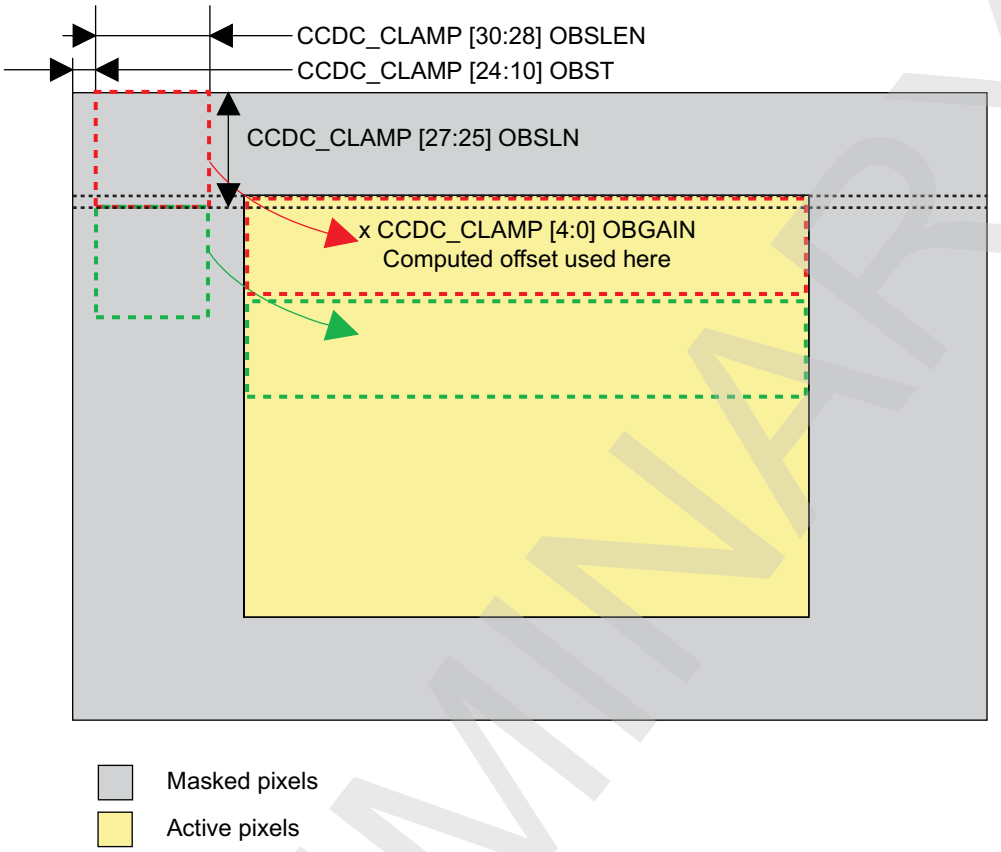
Alternately, users can disable black clamp averaging (CCDC_CLAMP [31] CLAMPEN) and select a constant black value for subtraction (CCDC_DCSUB [13:0] DCSUB), instead of using the calculated average value.

NOTE: For YUV data, this operation subtracts a fixed value (CCDC_DCSUB [13:0] DCSUB) from the luminance sample. To disable this operation, set the subtraction value to zero. This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes (CCDC_SYN_MODE [13:12] INPMOD == 2 || CCDC_REC656IF [0] REC656ON == 1).

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes (CCDC_SYN_MODE [13:12] INPMOD == 2 || CCDC_REC656IF [0] REC656ON == 1).

Figure 6-78 shows an optical clamp representation.

Figure 6-78. Camera ISP CCDC Optical Clamp Representation



Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset (CCDC_BLKCMP register, fields R_YE, GR_CY, GB_G, B_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position (CCDC_COLPTN). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, VGA Movie Mode).

Faulty-Pixel Correction

Faulty-pixel correction in the CCDC module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCDC module implements an optional (CCDC_FPC [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The CCDC_FPC_ADDR register specifies the starting address in memory for the faulty-pixel correction table.

NOTE: The memory address must be 64-byte-aligned (6 LSB are ignored).

NOTE: For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed (CCDC_FPC [15] FPCEN).

6.4.6.1.3.4 Camera ISP CCDC Data Formatter, Lens-Shading Compensation, and Video-Port Interface

NOTE: For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed (CCDC_FMTCFG [15] VPEN = 0x0 and CCDC_SYN_MODE [18] VP2SDR = 0x0).

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the Resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When CCDC_SYN_MODE [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the CCDC_SYN_MODE [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by CCDC_FMTCFG [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output (CCDC_SYN_MODE [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- CCDC_HD_VD_WID[27:16] HDW
- CCDC_HD_VD_WID[11:0] VDW
- CCDC_PIX_LINES[31:16] PPLN
- CCDC_PIX_LINES[15:0] HLPRF

NOTE: These four registers are not used when HS/VS signals are input signals (CCDC_SYN_MODE [16] VDHDEN = 0x0).

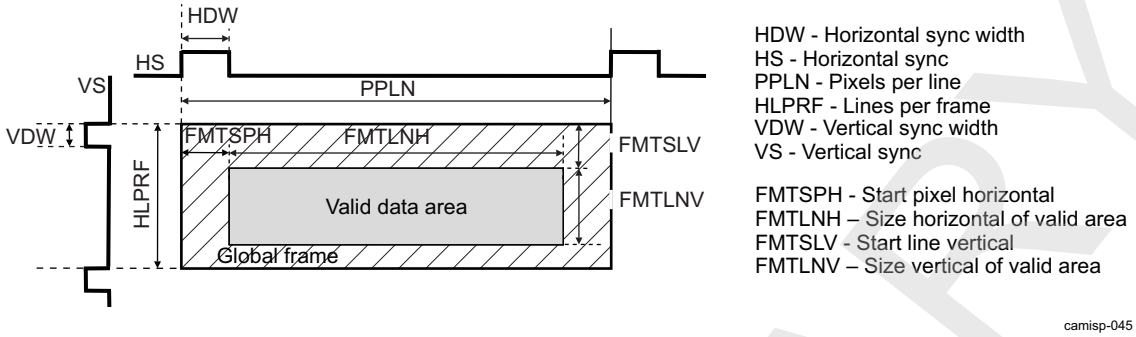
NOTE: The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

Registers CCDC_FMT_HORZ and CCDC_FMT_VERT affect the input framing even if data formatter is disabled.

Registers CCDC_HORZ_INFO, CCDC_VERT_START, and CCDC_VERT_LINES control the output formatter framing. It is used only when the CCDC output is sent to memory.

Figure 6-79 shows the data formatter conversion area selection.

Figure 6-79. Camera ISP CCDC Data Formatter Conversion Area Selection



Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode (CCDC_FMTCFG [1] LNALT).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0th input line is output as the first line, the first input line is output as the 0th line, and so on. If this option is set, the start and number of lines for the formatter (CCDC_VERT_START and CCDC_VERT_LINES) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in Table 6-36.

Table 6-36. Camera ISP CCDC Reformatter Output Limitations

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either auto increment or auto decrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- CCDC_FMTCFG [3:2] LNUM
  Number of lines into which each input line is to be decomposed
- CCDC_FMTCFG [11:8] PLEN_EVEN
  Number of program entries on even line
- CCDC_FMTCFG [7:4] PLEN_ODD
  Number of program entries on odd line
- CCDC_FMT_ADDRx (x=0:7)
  Output line in which the original pixel is to be placed, and initial address on the output line
- CCDC_PRGEVEN0 or CCDC_PRGEVEN1
  Program to be run on the even input lines
- CCDC_PRGODD0 or CCDC_PRGODD1
  Program to be run on the odd input lines

The CCDC_FMT_ADDRx registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

Lens-Shading Compensation

- *Overview*

  The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

  The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- *Features supported*
  - The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and N M
  - 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
  - Up to 10-bit unsigned image data input/output
  - Up to 4096 x 3072 image dimension

- *Functional description*

  The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

  Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensors preview mode image data.

6.4.6.1.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting CCDC_HORZ_INFO, CCDC_VERT_START, and CCDC_VERT_LINES registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected (CCDC_SYN_MODE [18] VP2SDR).

The option to send the CCDC output to the Resizer module (CCDC_SYN_MODE [19] SDR2RSZ) should not be used when in RAW data mode, because the Resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

Low-Pass Filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied (CCDC_SYN_MODE [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, /12, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled (CCDC_SYN_MODE [14] LPF = 0x0).

Culling

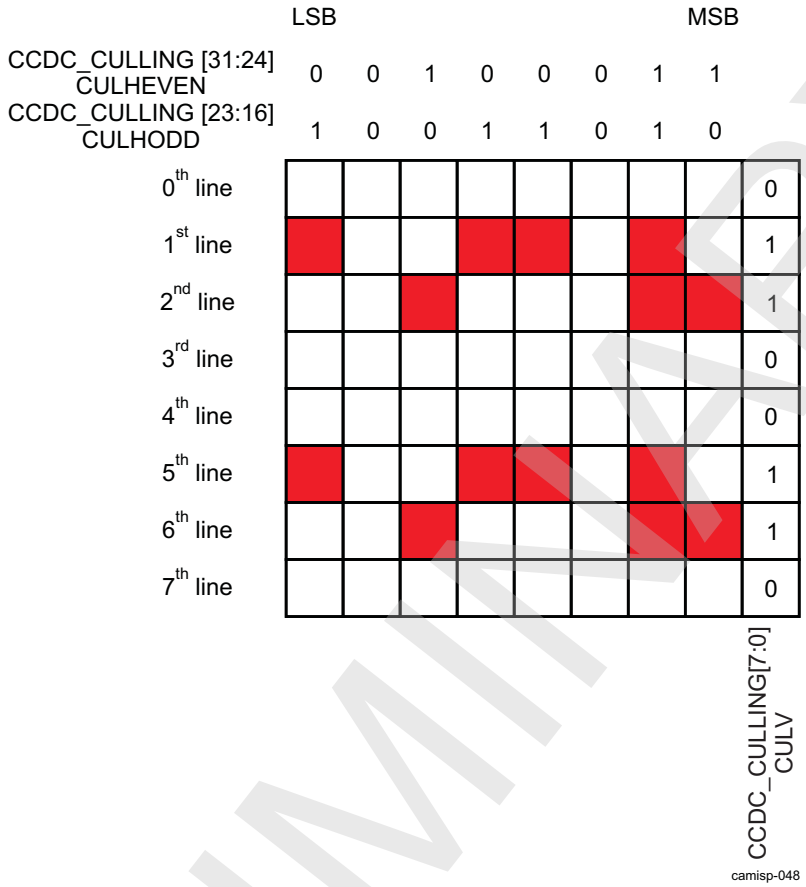
An optional culling operation can be enabled (CCDC_CULLING register). This operation allows selected pixel data to be culled (deleted) from a line (CCDC_CULLING [31:24] CULHEVN, CCDC_CULLING [23:16] CULHODD - 8-bit repeating mask, one per field) and selected lines to be culled from a frame (CCDC_CULLING [7:0] CULV).

Figure 6-80 is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, CCDC_CULLING = 0x239A0066:

- CCDC_CULLING [31:24] CULHEVN = 0x23
- CCDC_CULLING [23:16] CULHODD = 0x9A
- CCDC_CULLING [7:0] CULV = 0x66

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

Figure 6-80. Camera ISP CCDC / Culling: Example for Decimation Pattern



A-Law Compression

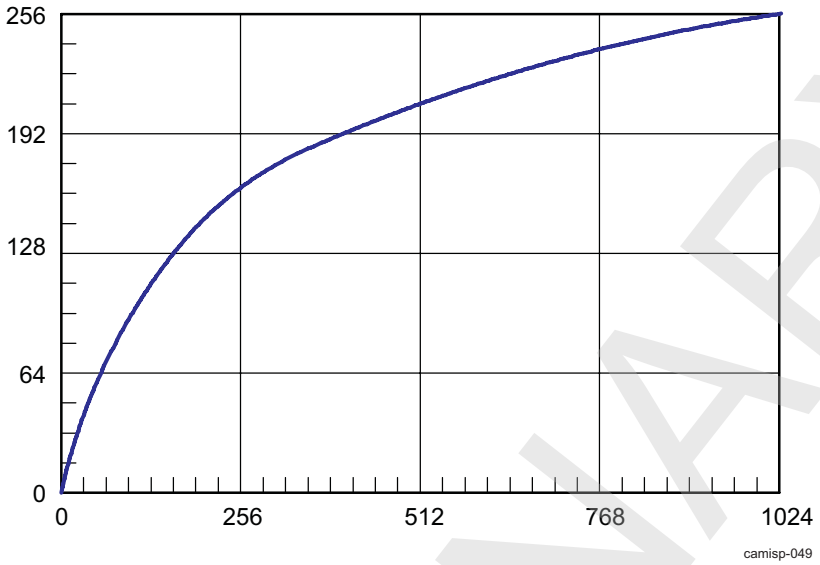
An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (CCDC_ALAW [3] CCDTBL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (CCDC_ALAW [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: A-Law compression should not be used (CCDC_ALAW [3] CCDTBL = 0) with YUV data.

Figure 6-81 show the A-Law table.

Figure 6-81. Camera ISP CCDC A-Law Table



Line-Output Control

NOTE: Line-output control can be used with YUV data.

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of CCDC_SDR_ADDR [31:0] ADDR defines the starting address where the frame should be written in memory. The value of CCDC_HSIZE_OFF [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the CCDC_SYN_MODE [11] PACK8 setting. Register CCDC_SDOFST can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See Table 6-37.

Table 6-37. Camera ISP CCDC CCDC_SDOFST Description

Register	Description
CCDC_SDOFST [14] FIINV	Invert interpretation of the field ID signal
CCDC_SDOFST [13:12] FOFST	Offset, in lines, of field = 1
CCDC_SDOFST [11:9] LOFTS0	Offset, in lines, between even lines on even fields (field 0)
CCDC_SDOFST [8:6] LOFTS1	Offset, in lines, between odd lines on even fields (field 0)
CCDC_SDOFST [5:3] LOFTS2	Offset, in lines, between even lines on odd fields (field 1)
CCDC_SDOFST [2:0] LOFTS3	Offset, in lines, between odd lines on odd fields (field 1)

Line Output Control: 2D Addressing Example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the CCDC_SDR_ADDR [31:0] ADDR register points to the first pixel to write and the CCDC_SDOFST [13:12] FOFST is set to the size of one line of the destination buffer.

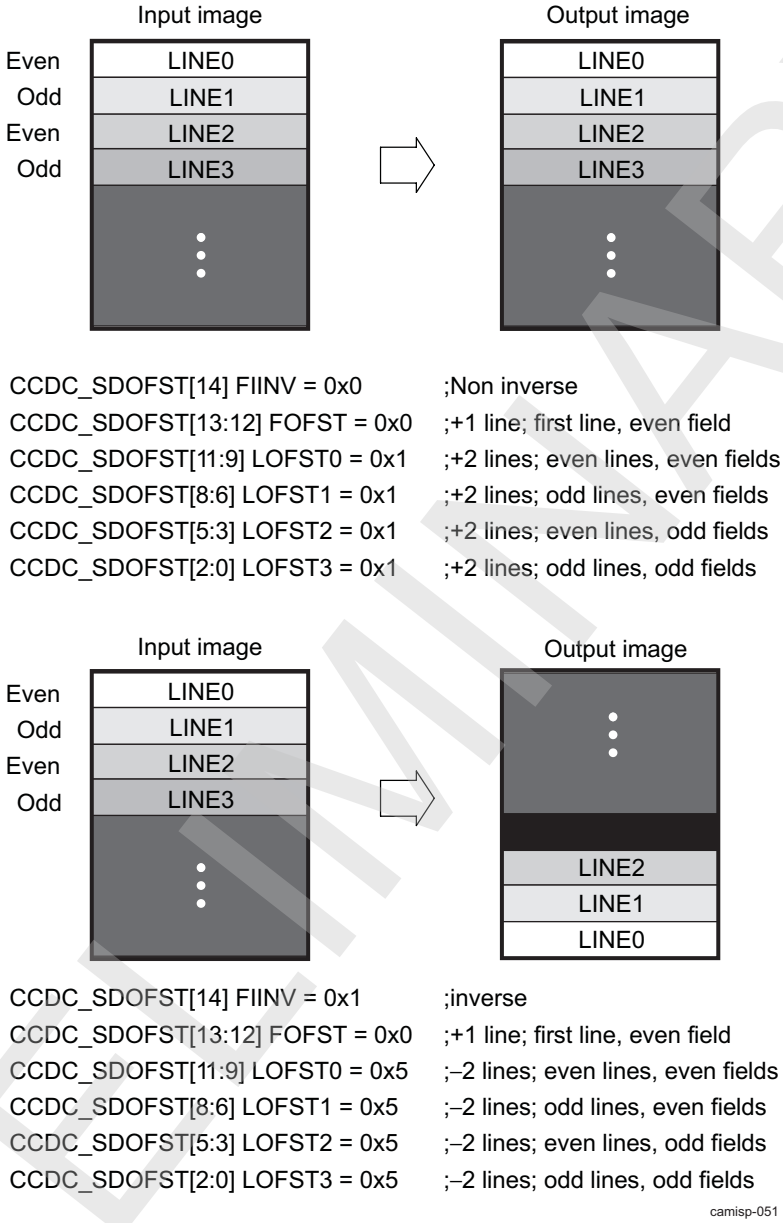
NOTE:

- This mode can be used only when the source and destination buffers use the same image format.
- 2D addressing is also supported by other camera ISP modules.

Line-Output Control: Examples

Figure 6-82 shows an example of sample formats of input and output images.

Figure 6-82. Camera ISP CCDC / Line-Output Control: Sample Formats of Input and Output Images



Output Format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in Table 6-38. The format is determined by the CCDC_SYN_MODE [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the CCDC_SYN_MODE [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the CCDC_SYN_MODE [17] WEN setting. The pixels are ordered in little-endian format.

Table 6-38. Camera ISP CCDC Memory Output Format for RAW Data

	Upper word								Lower word							
	MSB(31)							LSB(16)	MSB(15)							LSB(0)
16 bit	Pixel 1								Pixel 0							
15 bit	0	Pixel 1							0	Pixel 0						
14 bit	0		Pixel 1						0		Pixel 0					
13 bit	0			Pixel 1					0			Pixel 0				
12 bit	0				Pixel 1				0				Pixel 0			
11 bit	0					Pixel 1			0					Pixel 0		
10 bit	0						Pixel 1		0						Pixel 0	
9 bit	0							Pixel 1	0							Pixel 0
8 bit	0							Pixel 1	0							Pixel 0
8-bit packed	Pixel 3							Pixel 2	Pixel 1							Pixel 0

NOTE: YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in Table 6-39.

Table 6-39. Camera ISP CCDC Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

6.4.6.1.4 Camera ISP CCDC DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

6.4.6.1.5 Camera ISP CCDC Memories

The CCDC module has one memory:

- REFORMATTER BUFFER: 3 x 1376 x 40 bits
- LSC PREFETCH BUFFER: 1536 x 32 bits

6.4.7 Camera ISP Video-Processing Back End

The video-processing back end (VPBE) comprises the preview and Resizer modules.

6.4.7.1 Camera ISP VPBE Preview Engine Features

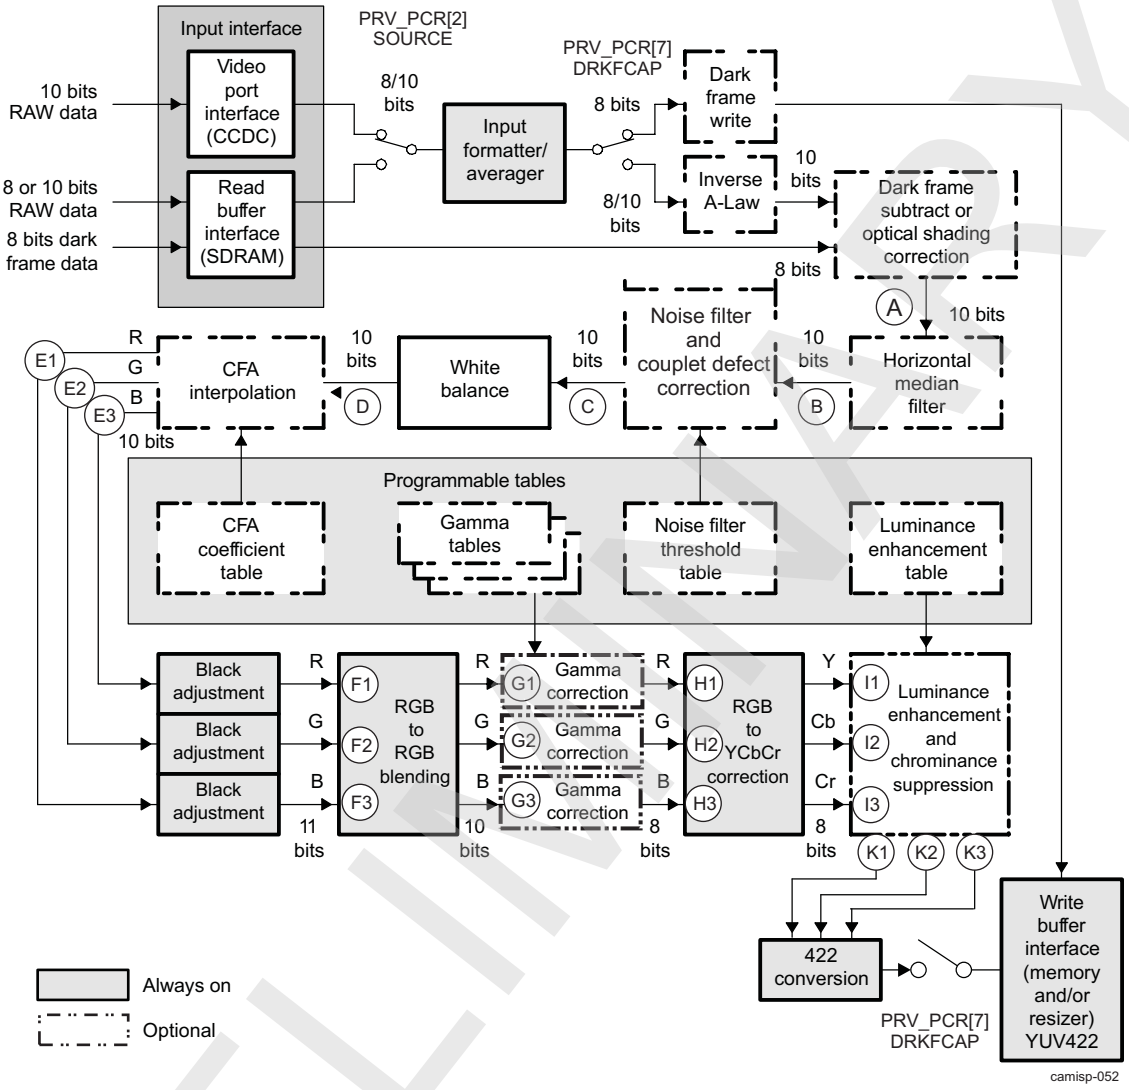
The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Super CCD Honeycom® sensors
- Horizontal averaging by a factor of 1, 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 4096 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
  - Dark-frame capture and subtraction
  - Horizontal median filter
  - Programmable noise filter: 3x3 kernel of same color pixels
  - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a 5x5 grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the 3x3 matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the 3x3 matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

6.4.7.1.1 Camera ISP VPBE Preview Block Diagram

Figure 6-83 shows the preview engine block diagram.

Figure 6-83. Camera ISP VPBE Preview Engine Block Diagram



6.4.7.1.2 Camera ISP VPBE Preview Input Interface

The preview engine receives RAW image/video data from the video port interface through the CCDC or from the read buffer interface through the memory (PRV_PCR [2] SOURCE). When the source of input data is the CCDC, the input data is always 10 bits wide. When the source of input data is memory (read buffer interface), the data can be 8 or 10 bits wide. Use the PRV_PCR[4] WIDTH field to set the input data width. The 8 bits can be linear or nonlinear (A-Law compressed).

In addition, the preview engine can fetch a dark frame from memory, with each pixel 8 bits wide.

The frame-input size is configured using the PRV_HORZ_INFO and PRV_VERT_INFO registers.

If the input source is the CCDC, the input height set in the preview engine must be less than or equal to the output height of the video-port output of the CCDC. The input width must be at least 4 pixels smaller than the CCDC output width (SPH >= 2; EPH >= 2 pixels before the last pixel sent from the CCDC).

The input memory address (PRV_RSDR_ADDR) and line offset (PRV_RADR_OFFSET) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address (PRV_DSDR_ADDR) and line offset (PRV_DRKF_OFFSET) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenable it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode (PRV_PCR [3] ONESHOT).

The SBL image data read port is shared between the preview and CSI1/CCP2B receiver module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the ISP_CTRL[27] SBL_SHARED_RPORTA. Programmers must ensure that the CSI1/CCP2B module does not use this port before switching to the preview module.

6.4.7.1.3 Camera ISP VPBE Preview Input Formatter/Averager

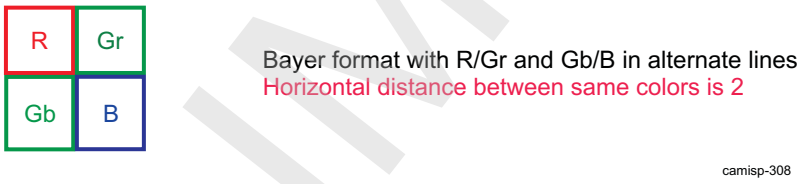
Preview-engine output is limited to 4096 pixels per horizontal line to support 12 Mpix, due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 4096 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction (PRV_AVE [1:0] COUNT). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even (PRV_AVE [3:2] EVENDIST) and odd (PRV_AVE [5:4] ODDDIST) lines. This must be configured to match the input pattern type.

For example, a Bayer pattern has a horizontal distance of two pixels of the same color for both even and odd lines.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

Figure 6-84 shows the horizontal distances for different patterns.

Figure 6-84. Camera ISP VPBE Preview Horizontal Distances for Different Patterns



6.4.7.1.4 Camera ISP VPBE Preview Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps (PRV_PCR [7] DRKFCAP).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The PRV_WSDR_ADDR and PRV_WADD_OFFSET registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

6.4.7.1.5 Camera ISP VPBE Preview Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled (PRV_PCR [5] INVALAW). Even if the inverse A-Law block is not enabled, but the input is still 8 bits (PRV_PCR [4] WIDTH), the data is-left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

NOTE: When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

6.4.7.1.6 Camera ISP VPBE Preview Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame (PRV_PCR [6] DRKFEN). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the PRV_PCR [31] DRK_FAIL status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if PRV_PCR [21] SCOMP_EN is set along with PRV_PCR [6] DRKFEN). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the PRV_PCR [24:22] SCOMP_SFT parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the ISP_CTRL [28] SBL_SHARED_RPORTB. Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

6.4.7.1.7 Camera ISP VPBE Preview Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

NOTE: Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656x490 pixels, the output is 652x490 pixels. There is no truncation of input data line if this block is disabled.

6.4.7.1.8 Camera ISP VPBE Preview Noise Filter and Faulty Pixel Correction

The noise filter and couplet defect correction (CDC) operate on the same 33 matrix of same color pixels. Both functions can be enabled separately using the PRV_PCR [27] DCOREN and PRV_PCR [9] NFEN bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled.

NOTE: Some details of these features are not available in public domain

6.4.7.1.9 Camera ISP VPBE Preview White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster (PRV_WB_DGAIN [9:0] DGAIN), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

In the white-balance gain adjuster (PRV_WBGAIN), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

NOTE: Some details of this feature are not available in public domain

6.4.7.1.10 Camera ISP VPBE Preview CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled (PRV_PCR [10] CFAEN) and configured to different interpolation modes (PRV_PCR [14:11] CFAFMT).

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.1 Camera ISP VPBE Preview CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.2 Camera ISP VPBE Preview CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

NOTE: Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

If the CFA format is 2 downsampling in both horizontal and vertical directions, only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

6.4.7.1.11 Camera ISP VPBE Preview Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

data_out = data_in + bl_offset

The bl_offset values for each color are programmable in the PRV_BLKADJOFF register and coded in S8Q0 format (-128..+127). A simple one addition and clip operation are processed in this module. The output data_out [10..0] is signed.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.12 Camera ISP VPBE Preview RGB Blending

The RGB2RGB blending module has a general 3x3 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable (PRV_RGB_MAT1, PRV_RGB_MAT2, PRV_RGB_MAT3, PRV_RGB_MAT4, PRV_RGB_MAT5, PRV_RGB_OFF1, & PRV_RGB_OFF2) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX\_RR & MTX\_GR & MTX\_BR \\ MTX\_RG & MTX\_GG & MTX\_BG \\ MTX\_RB & MTX\_GB & MTX\_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX\_OFFR \\ MTX\_OFFG \\ MTX\_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$MTX\_RR = MTX\_GG = MTX\_BB = 256$$
$$others = 0$$

camisp-E162

6.4.7.1.13 Camera ISP VPBE Preview Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed (PRV_PCR [26] GAMMA_BYPASS). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

6.4.7.1.14 Camera ISP VPBE Preview RGB to YCbCr Conversion, Luminance Enhancement, Chrominance Suppression, Contrast and Brightness, and 4:2:2 Downsampling and Output Clipping

6.4.7.1.14.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 3x3 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the PRV_CSC0, PRV_CSC1, PRV_CSC2, and PRV_CSC_OFFSET registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

NOTE: Program the following values after reset for correct color conversion:

- PRV_CSC2 [19:10] CSCGCR = 0x39E
- PRV_CSC2 [9:0] CSCRCR = 0x080

6.4.7.1.14.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the PRV_PCR [15] YNENHEN parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the PRV_PCR [16] SUPEN parameter.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the PRV_CNT_BRT [15:8] CNT field (U8Q4 precision), and brightness is set in the PRV_CNT_BRT [7:0] BRT field (U8Q0 precision).

6.4.7.1.14.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the PRV_SETUP_YC register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

6.4.7.1.15 Camera ISP VPBE Preview Write-Buffer Interface

The output of the preview engine may be passed directly to the Resizer (PRV_PCR [19] RSZPORT) and/or written to memory (PRV_PCR [20] SDRPORT).

If the output is written to memory, the write address (PRV_WSDR_ADDR) and line offset (PRV_WADD_OFFSET) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the PRV_PCR [18:17] YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. Table 6-40 indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

Table 6-40. Camera ISP VPBE Preview Image Cropping by Preview Functions

Image Cropping by Preview Functions		
Function	**Pix/Line**	**Lines**
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Super CCD Honeycom or RGBE)	4	4
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

NOTE: Different CFA modes are mutually exclusive.

6.4.7.2 Camera ISP VPBE Resizer

6.4.7.2.1 Camera ISP VPBE Resizer Features

The Resizer module enables image upsampling and downsampling, see Table 6-41. The following features are supported:

- Flexible input sources:
  - Preview module: Enables on-the-fly processing

  - Memory: Enables differed processing
  - Memory: CCDC module: Enables on-the-fly processing
- Flexible input format:
  - YUV422 packed data (16 bits)
  - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory: not available for on-the-fly processing.
  - Same output format as input
- Upsampling: Up to 4. Enables digital zoom:
  - General polyphase filter:
    - Ratio of 1 to 4: 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25:
  - General polyphase filter:
    - Ratio of 0.25 to 0.5: 7 taps (horizontal and vertical) and 4 phases
    - Ratio of 0.5 to 1: 4 taps (horizontal and vertical) and 8 phases
- Constraints:
  - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

Table 6-41. Camera ISP VPBE Resizer Use Constraints

Resizer Use Constraints			Horizontal Resizer Ratio	
			0.25 to 0.5	0.5 to 4
			7 taps	4 taps
Vertical Resizer ratio	0.25 to 0.5	7 taps	OW<=2048	OW<=2048
	0.5 to 4	4 taps	OW<=4096	OW<=4096

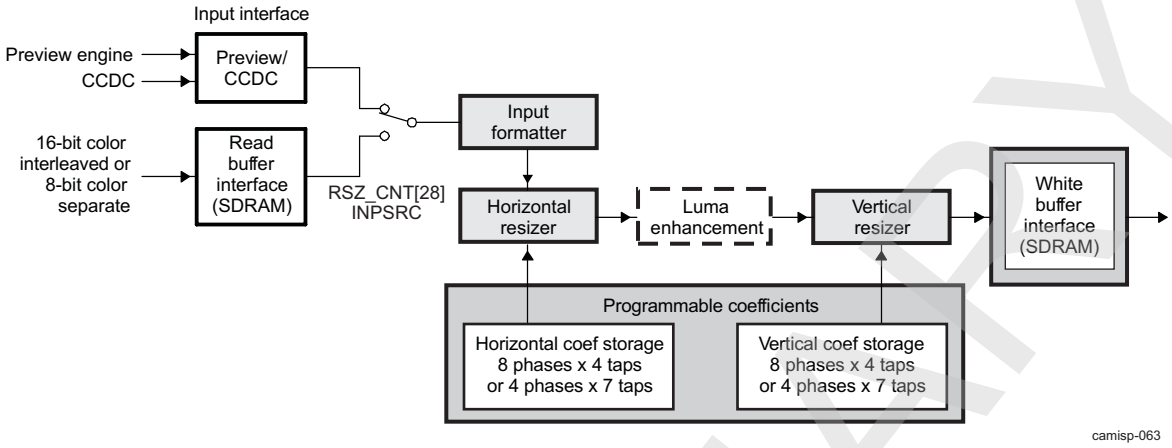
  - The horizontal resizer output rate must not exceed half the functional clock; Moreover, the horizontal resizer output rate must not exceed 100M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is 256/N, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

6.4.7.2.2 Camera ISP VPBE Resizer Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25 to 4 resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in Figure 6-85.

Figure 6-85. Camera ISP VPBE Resizer Process



6.4.7.2.3 Camera ISP VPBE Resizer Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory (RSZ_CNT [28] INPSRC). The input width (RSZ_IN_SIZE [12:0] HORZ) must be at least 32 pixels.

6.4.7.2.3.1 Camera ISP VPBE Resizer Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte (RSZ_IN_START [12:0] HORZ_ST) and vertical starting line (RSZ_IN_START [28:16] VERT_ST) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the RSZ_IN_SIZE register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

NOTE: Care must be taken to ensure that the input sizes specified by the RSZ_IN_START and RSZ_IN_SIZE registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

RSZ_SDR_INADD and RSZ_SDR_INOFF must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC (CCDC_SYN_MODE [19] SDR2RSZ) and preview engine (PRV_PCR [19] RSZPORT) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

6.4.7.2.3.2 Camera ISP VPBE Resizer Memory-Input Mode

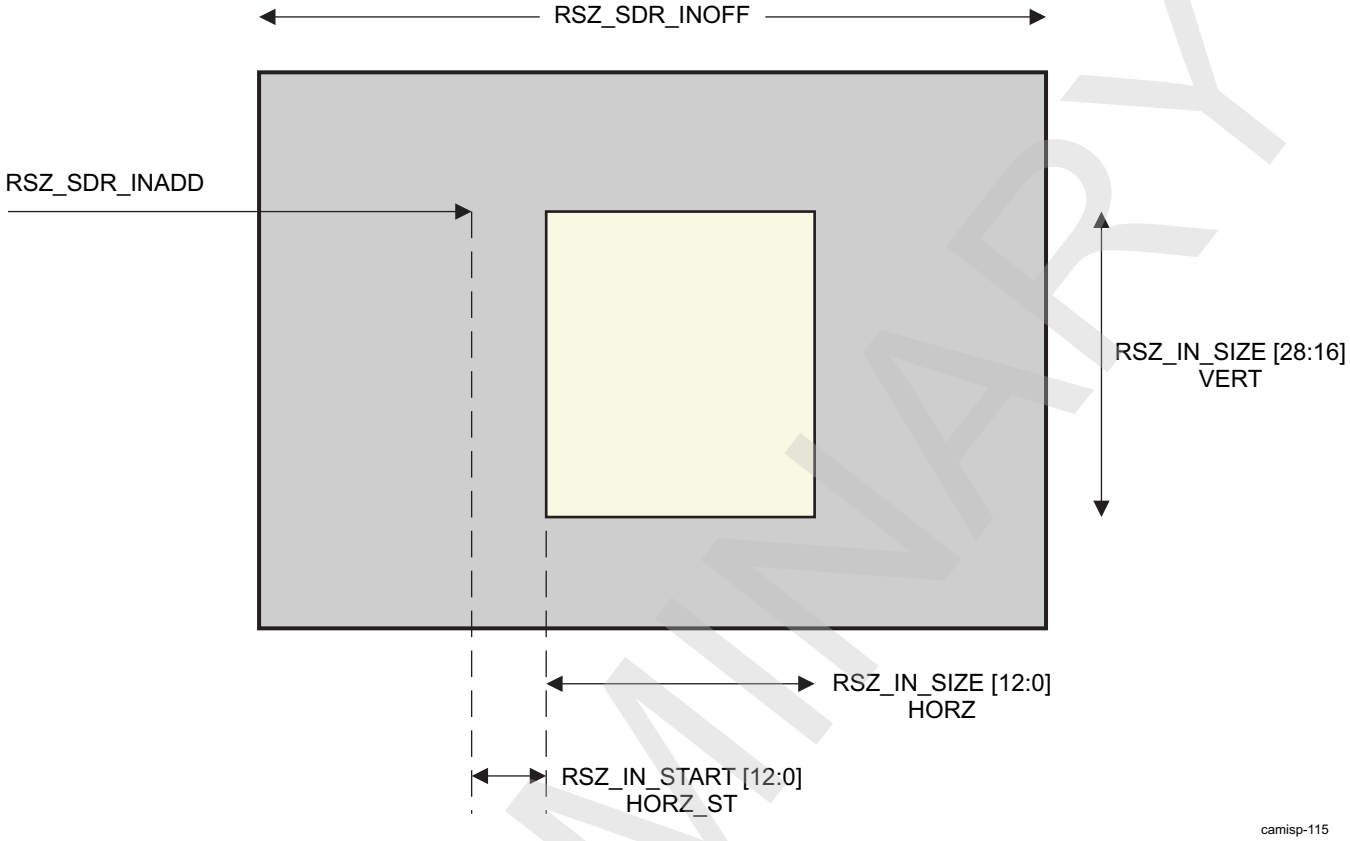
In memory-input mode, the memory address in RSZ_SDR_INADD points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel (RSZ_IN_START [12:0] HORZ_ST) defines a starting pixel within that 32-byte alignment; HORZ_ST is constrained to 0...15 for the YUV 422 format, and 0...31 for the color-separated format.

The vertical starting pixel (RSZ_IN_START [28:16] VERT_ST) must be zero in memory-input mode. The RSZ_SDR_INOFF register specifies the address offset between rows of input data. The input width and height in the RSZ_IN_SIZE register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Figure 6-86 shows the resizer in memory-input mode.

Figure 6-86. Camera ISP VPBE Resizer Resizer in Memory-Input Mode



6.4.7.2.3.3 Camera ISP VPBE Resizer Output Interface

In both input modes, the RSZ_OUT_SIZE register specifies output width/height, the RSZ_SDR_OUTADD register specifies output starting pixel (upper-left corner) memory address, and the RSZ_SDR_OUTOFF register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

NOTE: RSZ_SDR_INADD, RSZ_SDR_OUTADD, RSZ_SDR_INOFF, and RSZ_SDR_OUTOFF must be 32-byte-aligned; the lower 5 bits of the byte address are assumed to be zero.

Output-width constraints: The output width (RSZ_OUT_SIZE [11:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width (RSZ_OUT_SIZE [11:0] HORZ) cannot be greater than:

- 4096 pixels if the vertical resizing ratio is between 1/2 and 4 ((RSZ_CNT [19:10] VRSZ + 1) <= 512)
- 1650 pixels wide if the vertical resizing ratio is between 1/2 and 1/4 ((RSZ_CNT [19:10] VRSZ + 1) > 512)

6.4.7.2.4 Camera ISP VPBE Resizer Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for RSZ_CNT [9:0] HRSZ + 1.
- VRSZ is used for RSZ_CNT [19:10] VRSZ + 1.

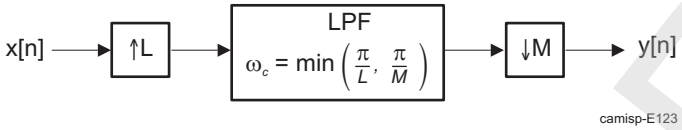
The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from 4 to 0.25 (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

Figure 6-87 shows a general sample-rate converter where the resampling rate is equal to L/M.

Figure 6-87. Camera ISP VPBE Resizer Typical Sample-Rate Converter



L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 4 for a resizing range of 1/4 ~1/2 (RSZ = 513 ~ 1024). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of 256/RSZ, the downsampling value (M) is equal to (PxRSZ)/256, where P is the number of phases. Figure 6-88 shows the resizer functionality.

Figure 6-88. Camera ISP VPBE Resizer Functionality

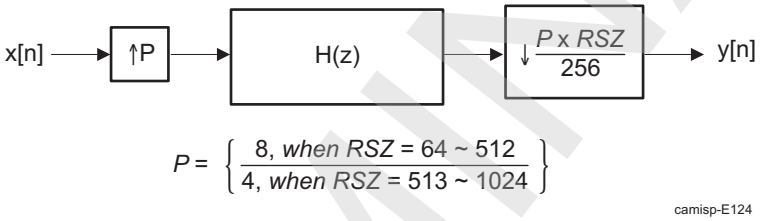


Figure 6-89 shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

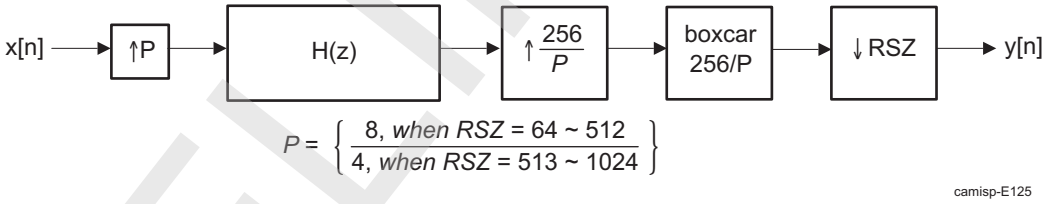
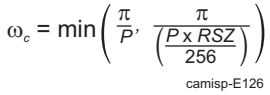
Figure 6-89. Camera ISP VPBE Resizer Approximation Scheme



This implementation means that a resizing ratio with 256/RSZ times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of 1/P input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in Figure 6-90.

Figure 6-90. Camera ISP VPBE Resizer Cutoff Frequency for Low-Pass Filter



If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers RSZ_HFILT10 to

RSZ_HFILT3130) and another 32 programmable coefficients are available for the vertical direction (registers RSZ_VFILT10 to RSZ_VFILT3130). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 7 taps and 4 phases for a resizing range of 1/4 ~1/2 (RSZ = 513 ~ 1024)(RSZ is either HRSZ or VRSZ). Table 6-42 shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

Table 6-42. Camera ISP VPBE Resizer Arrangement of the Filter Coefficients

Filter Coefficient	0.5x to 4x		0.24x to ~0.5x	
	Phase	Tap	Phase	Tap
0	0	0	0	0
1		1		1
2		2		2
3		3		3
4	1	0		4
5		1		5
6		2		6
7		3		Not used

15		3		Not used
16	4	0		
17		1		
18		2		
19		3		
20	5	0		
21		1		
22		2		
23		3		Not used
24	6	0	3	0
25		1		1
26		2		2
27		3		3
28	7	0		4
29		1		5
30		2		6
31		3		Not used

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. Figure 6-91 shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

Figure 6-91 shows the alignment of input pixels to tap coefficients.

Figure 6-91. Camera ISP VPBE Resizer Alignment of Input Pixels to Tap Coefficients

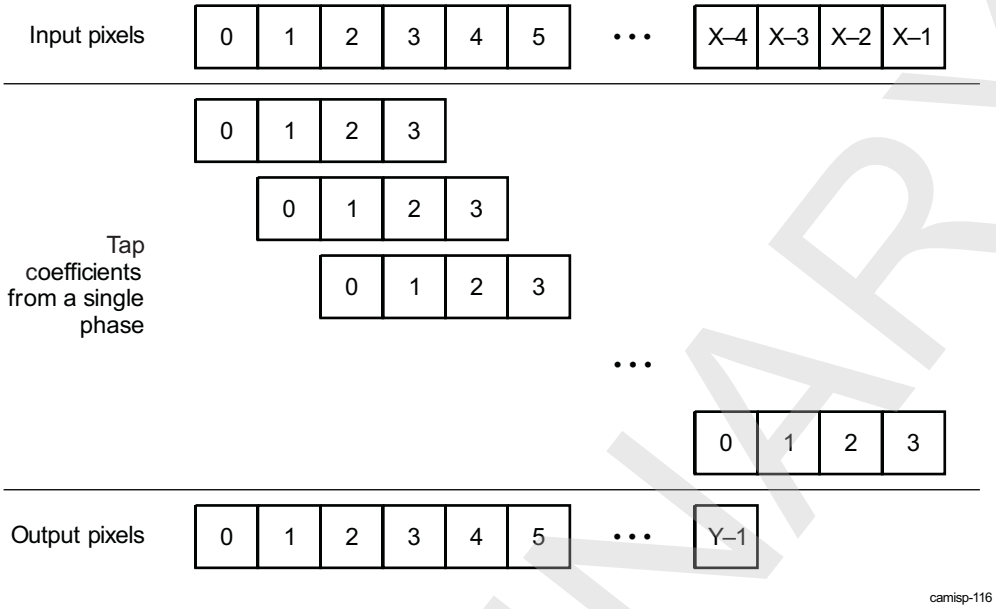

Figure 6-91 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

input size = output size*RSZ/256

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

X = Y*256/256 + 3 (to account for the extra pixels required for filtering)

The input size calculation depends on the starting phase and rounding issues in the algorithm. Table 6-43 lists the input size calculations derived from the algorithm description in Section 6.4.7.2.5. The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

Table 6-43. Camera ISP VPBE Resizer Input Size Calculations

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
RSZ_IN_SIZE[12:0] HORZ	(32*sph + (ow - 1)*hrsz + 16) >> 8 + 7	(64*sph + (ow - 1)*hrsz + 32) >> 8 + 7
RSZ_IN_SIZE[28:16] VERT	(32*spv + (oh - 1)*vrsz + 16) >> 8 + 4	(64*spv + (oh - 1)*vrsz + 32) >> 8 + 7

Where:

sph = Start phase horizontal (RSZ_CNT [22:20] HSTPH)

spv = Start phase vertical (RSZ_CNT [25:23] VSTPH)

ow = Output width (RSZ_OUT_SIZE [11:0] HORZ + extra)

oh = Output height (RSZ_OUT_SIZE [27:16] VERT)

hrsz = Horizontal resize value (RSZ_CNT [9:0] HRSZ + 1)

vrsz = Vertical resize value (RSZ_CNT [19:10] VRSZ + 1)

extra = 0 when RSZ_YENH [17:16] ALGO = 0 (edge enhancement disabled)
extra = 4 when RSZ_YENH [17:16] ALGO != 0 (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the RSZ_CNT [22:20] HSTPH and RSZ_CNT [25:23] VSTPH fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data (RSZ_CNT [29] CBILIN).

The following section explains how these fields are used in the algorithm.

6.4.7.2.5 Camera ISP VPBE Resizer Resampling Algorithm

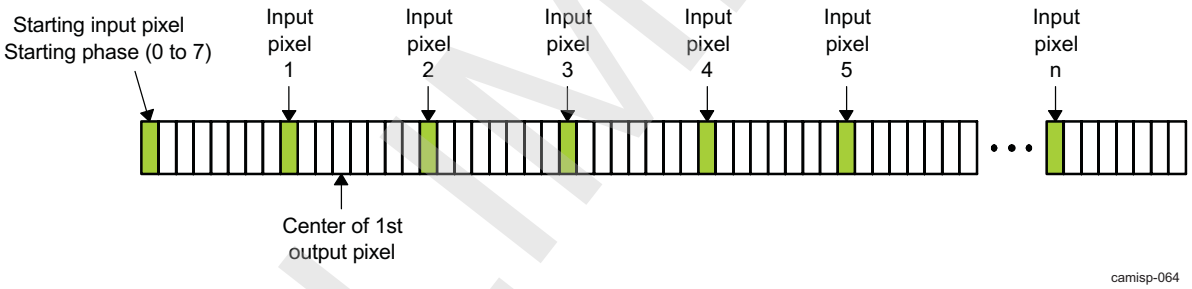
The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

Section 6.4.7.2.5.1 and Section 6.4.7.2.5.2 explain the generic algorithm without detailing the differences between color components. Section 6.4.7.2.5.3 describes how interleaved chroma are processed when input is YUV422.

6.4.7.2.5.1 Camera ISP VPBE Resizer 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/256 input-pixel precision is incremented by the RSZ_CNT [9:0] HRSZ +1 value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. Figure 6-92 shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

Figure 6-92. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode



- The starting input pixel location (in whole pixels) (see Section 6.4.7.2.3, *Camera ISP VPBE Resizer Input and Output Interfaces*) and the starting phase (in 1/8 pixel) (RSZ_CNT [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256* starting input pixel + 32* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

```
Coarse-input pointer =                  /* Rounded to the nearest phase */
(fine-input pointer + 16) >> 5
Pixel-input pointer =                   /* Rounded up to a whole pixel, when already on an
(coarse-input pointer >> 3) + 1             integer pixel, go to next one to simplify coefficient
                                            organization */
Coefficient phase =                     /* 3 LSBs = phase */
(coarse-input pointer & 7)
Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma
```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ +1)

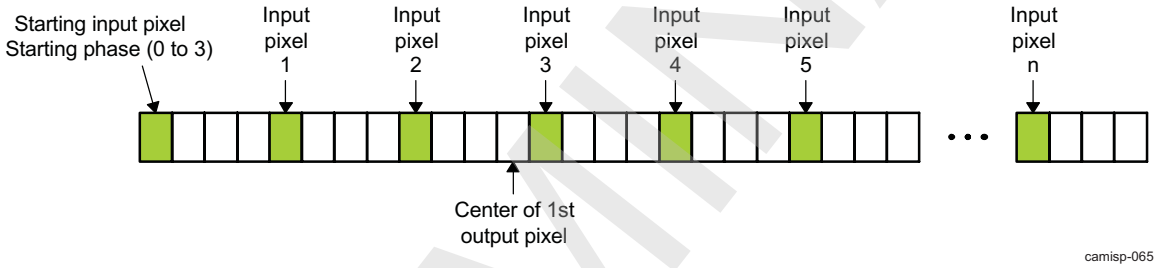
/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) /256 = (RSZ_CNT [9:0] HRSZ + 1) in 1/256 precision */

- Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values and separate RSZ values.

6.4.7.2.5.2 Camera ISP VPBE Resizer 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the RSZ_CNT [9:0] HRSZ + 1 value. A coarse-input pointer with 1/2 input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest 1/2 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 6-93 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

Figure 6-93. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode



- The starting input-pixel location (in whole pixels) (see Section 6.4.7.2.3, *Camera ISP VPBE Resizer Input and Output Interfaces*) and the starting phase (in 1/2 pixel) (RSZ_CNT [22:20] HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in 1/2 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256 * starting input pixel + 64 * starting phase - 256. The fine-input pointer defines the starting 1/2 pixel location covered by the filter waveform.
- For each output pixel:

Coarse-input pointer = (fine-input pointer + 32) >> 6 /* Round to the nearest phase */

Pixel-input pointer = (coarse-input pointer >> 2) + 1 /* Round up to a whole pixel; when already on an integer pixel, go to next one to simplify coefficient organization */

Coefficient phase = (coarse-input pointer & 3) /* 2 LSBs = phase */

Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input pointer

Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8 coefficients and 8 inputs, the last input being *don't care* value, are multiply-added */

Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)

/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 = (RSZ_CNT [9:0] HRSZ + 1) in 1/256 precision */

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

NOTE: The pixel-input pointer (pip) in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer (fip) points to a 1/256 resolution sub-pixel position. The coarse-input point (cip) points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

6.4.7.2.5.3 Camera ISP VPBE Resizer Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the RSZ_CNT [29] CBILIN field independently of the RSZ_CNT [22:20] HSTPH parameters. However, filtering with luma is intended only for downsampling, and bilinear interpolation is intended only for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

Filter Chroma With Luma (4-Tap/8-Phase Mode):

```
For (i=0; i<output_width; i++) { /* output width depends of input width and resizing factors*/
        Coarse-input pointer = (fine-input pointer + 16) >> 5     /* Round to nearest phase */
        Pixel-input pointer = (coarse-input pointer >> 3) + 1     /* Round up to a whole pixel */
        Coefficient phase = pixel-input pointer & 7               /* 3 LSB = phase */
        if (i & 1 == 0) { /* even output pixel, generate YCbCr */
            Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
            Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with
            pixel-input pointer
            Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with
            pixel-input pointer
            Clip outputs to 8-bit unsigned for luma, 8-bit
            signed for chroma
        }
        Else {/* odd output pixel, generate Y only */
            Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
            Clip output to 8-bit unsigned
        }
        Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
        }
```

Filter Chroma With Luma (7-Tap/4-Phase Mode):

```
For (i=0; i<output_width; i++) { /* output width depends of input width and resizing factors*/
        Coarse-input pointer = (fine-input pointer + 32) >> 5     /* Round to nearest phase */
        Pixel-input pointer = (coarse-input pointer >> 2) + 1     /* Round up to a whole pixel */
        Coefficient phase = pixel-input pointer & 3               /* 2 LSB = phase */
        if (i & 1 == 0) { /* Even output pixel, generate YCbCr
        */
            Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
            Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with
            pixel-input pointer
            Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with
            pixel-input pointer
            Clip outputs to 8-bit unsigned for luma, 8-bit
            signed for chroma
        }
        Else {/* Odd output pixel, generate Y only */
            Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
            Clip output to 8-bit unsigned
        }
        Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
   }
```

NOTE: The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

Bilinear Interpolation (4-Tap or 7-Tap):

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```
For (i=0; i<output_width; i++) {
    if (i & 1 == 0) { /* even output pixel, generate YCbCr */
        Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
        taps*/
        Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
        Yout = dot product of ... /*Calculation issued from 4 taps or 7
        taps*/
        C_fine_input_pointer = fine_input_pointer + 128*ntaps     /* Points to center of filter
                                                                  kernel */
        Cidx = C_fine_input_pointer >> 9                          /* Truncate to even pixel
                                                                  grid to find left value */
        Cbin[0] = Cb[Cidx]
        Cbin[1] = Cb[Cidx + 1]
        Crin[0] = Cr[Cidx]
        Crin[1] = Cr[Cidx + 1]
        frac = C_fine_input_pointer & 511                         /* 9-bit fraction */
        Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) >> 9
        Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) >> 9
```

```
            Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
            Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
            Else {/* odd output pixel, generate Y only */
            . . .
            }
    }
```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction f. Thus, 1- f becomes 512 - frac. After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in RSZ_CNT [26] YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

6.4.7.2.5.4 Camera ISP VPBE Resizer Algorithm Functionality

Table 6-44 is an example of 1:2.56 (hrsz = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

Table 6-44. Camera ISP VPBE Resizer Processing Example for 1:2:56 Horizontal Resize

Output	Y0	Cb0	Cr0	Y1	Y2	Cb2	Cr2	Y3	Y4	Cb4	Cr4	Y5
fip (+= hrsz)	-256			-156	-56			44	144			244
cip (= (fip+16)>>5)	-8			-5	-2			1	5			8
pip (= (cip>>3) + 1)	0			0	0			1	1			2
coef ph (= cip & 7)	0			3	6			1	5			0
Inputs needed (chroma filtered like luma)	Y0	Cb0	Cr0	Y0	Y0	Cb0	Cr0	Y1	Y1	Cb0	Cr0	Y2
	Y1	Cb2	Cr0	Y1	Y1	Cb0	Cr0	Y2	Y2	Cb2	Cr2	Y3
	Y2	Cb2	Cr2	Y2	Y2	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4
	Y3	Cb2	Cr2	Y3	Y3	Cb2	Cr2	Y4	Y4	Cb4	Cr4	Y5
Cfip (= fip+512)		256				488				720		
Cidx (= Cfip >> 9)		0				0				1		
Inputs needed for chroma bilinear interpolation		Cb0	Cr0			Cb0	Cr0			Cb2	Cr2	
		Cb2	Cr2			Cb2	Cr2			Cb4	Cr4	

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The Cidx of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so Cidx = 1 means we Cb2 and Cb4 are being grabbed.

6.4.7.2.6 Camera ISP VPBE Resizer Luma Edge Enhancement

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The RSZ_YENH [17:16] ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The RSZ_OUT_SIZE [11:0] HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be RSZ_OUT_SIZE [11:0] HORZ + 4.

NOTE: Some details of this feature are not available in the public domain,

RSZ_YENH [7:0] CORE is in U8Q0. RSZ_YENH [11:8] SLOP is in U4Q4. RSZ_YENH [15:12] GAIN is in U4Q4.

6.4.8 Camera ISP Statistics Collection Modules

The statistics-collection modules (SCMs) are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

6.4.8.1 Camera ISP H3A

6.4.8.1.1 Camera ISP H3A Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus engine (AF):

  The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:
  - Peak mode in a paxel (a paxel is defined as a two dimensional block of pixels): Accumulate the maximum focus value of each line in a paxel.
  - Accumulation of the maximum focus value of each line in a paxel
  - Accumulation mode
  - Accumulation/sum mode (instead of peak mode): Accumulation of focus value in a paxel
  - Up to 36 paxels/windows in the horizontal direction and up to 128 paxels/windows in the vertical direction
  - Programmable width and height for the paxel/window
  - Programmable red, green, and blue position within a 2x2 matrix
  - Separate horizontal start for paxel and filtering
  - Programmable vertical line increments within a paxel
  - Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)
- Auto exposure and auto white balance engine (AE/AWB)

  The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:
  - Accumulation of clipped pixels along with all nonsaturated pixels
  - Up to 36 horizontal windows/paxel and up to 128 vertical windows/paxel
  - Separate vertical start coordination and height for a black row of paxels different from the remaining color paxels
  - Programmable horizontal and vertical sampling points in a window

NOTE: Some details of this feature are not available in the public domain.

6.4.8.1.2 Camera ISP H3A Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each paxel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

6.4.8.1.3 Camera ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

6.4.8.2 Camera ISP Histogram

6.4.8.2.1 Camera ISP Histogram Features

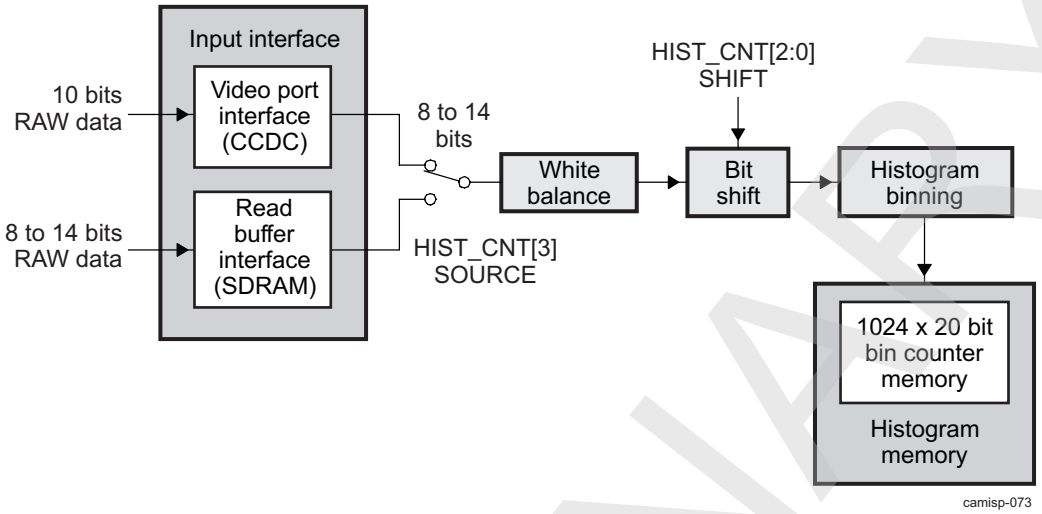
The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support 4 colors (Bayer), and up to 4 regions, simultaneously. Figure 6-94 shows the processing of the histogram module.

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
  - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
  - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
  - Programmable regions: There can be up to four regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
  - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.
  - Color components: A histogram is computed for each color component in the RAW image. There are usually 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds 2^{20}-1, the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

6.4.8.2.2 Camera ISP Histogram Block Diagram

Figure 6-94. Camera ISP Histogram Process



6.4.8.2.3 Camera ISP Histogram Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory (HIST_CNT [3] SOURCE).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the HIST_CNT [8] DATSIZ bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address (HIST_RADD) and line-offset (HIST_RADD_OFF) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the HIST_H_V_INFO [29:16] HSIZE and HIST_H_V_INFO [13:0] VSIZE register fields, respectively.

The histogram module supports 4-color Bayer color patterns. The HIST_CNT [6] CFA field is used to select the color pattern of the input data (Bayer).

6.4.8.2.4 Camera ISP Histogram White Balance

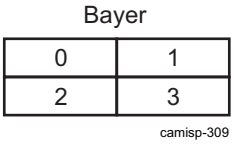
A white-balance gain can be separately applied to each color channel by programming the fields in the HIST_WB_GAIN register. Table 6-45 indicates which pixel index in the color pattern corresponds to each field in the WB_GAIN register.

Table 6-45. Camera ISP Histogram White Balance Field-to-Pattern Assignments

HIST_WB_GAIN fields	Bayer
WG00	0
WG01	1
WG02	2
WG03	3

NOTE: There are four different physical locations, with one color per location for Bayer. See Figure 6-95.

Figure 6-95. Camera ISP Histogram Color Pattern Index



Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

6.4.8.2.5 Camera ISP Histogram Binning

The histogram bins the input data by amplitude, color, and region (see Figure 6-96). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the HIST_CNT [5:4] BINS field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in Table 6-46.

Table 6-46. Camera ISP Histogram Regions and Bins

Number of Bins	Number of Regions Allowed
256	1
128	2
64	4
32	4

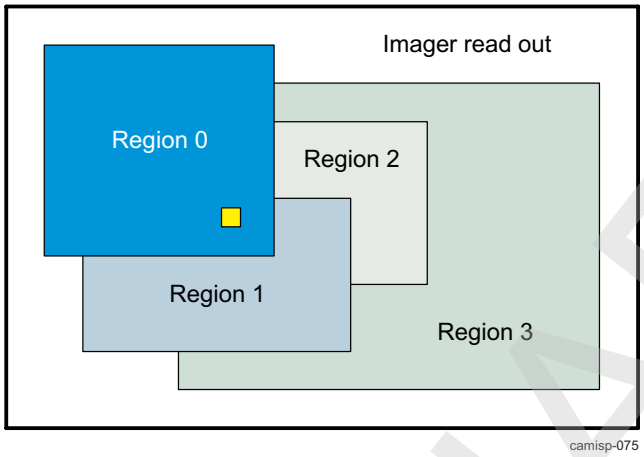
As indicated by Table 6-46, up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting (HIST_Rn_HORZ [29:16] HSTART) and ending (HIST_Rn_HORZ [13:0] HEND) pixels, and the vertical starting (HIST_Rn_VERT [29:16] VSTART) and ending (HIST_Rn_VERT [13:0] VEND) lines (where n is the region number 0...3).

NOTE: If the starting and ending pixels/lines are the same, the region size is treated as zero, and there is no binning for such a region.

6.4.8.2.5.1 Camera ISP Histogram Region Priority

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 > Region 1 > Region 2 > Region 3. For example, the yellow pixel in Figure 6-96 is binned only for Region 0, although it is present in all four regions.

Figure 6-96. Camera ISP Histogram Region Priority



6.4.9 Camera ISP Central-Resource Shared Buffer Logic

The central-resource shared buffer logic (SBL) receives data read and write requests from the CCDC, preview, H3A, histogram, resizer, CSI2A, CSI2C, and CSI1/CCP2B modules. It arbitrates between requesters and constructs bursts to transfer data to and from memory.

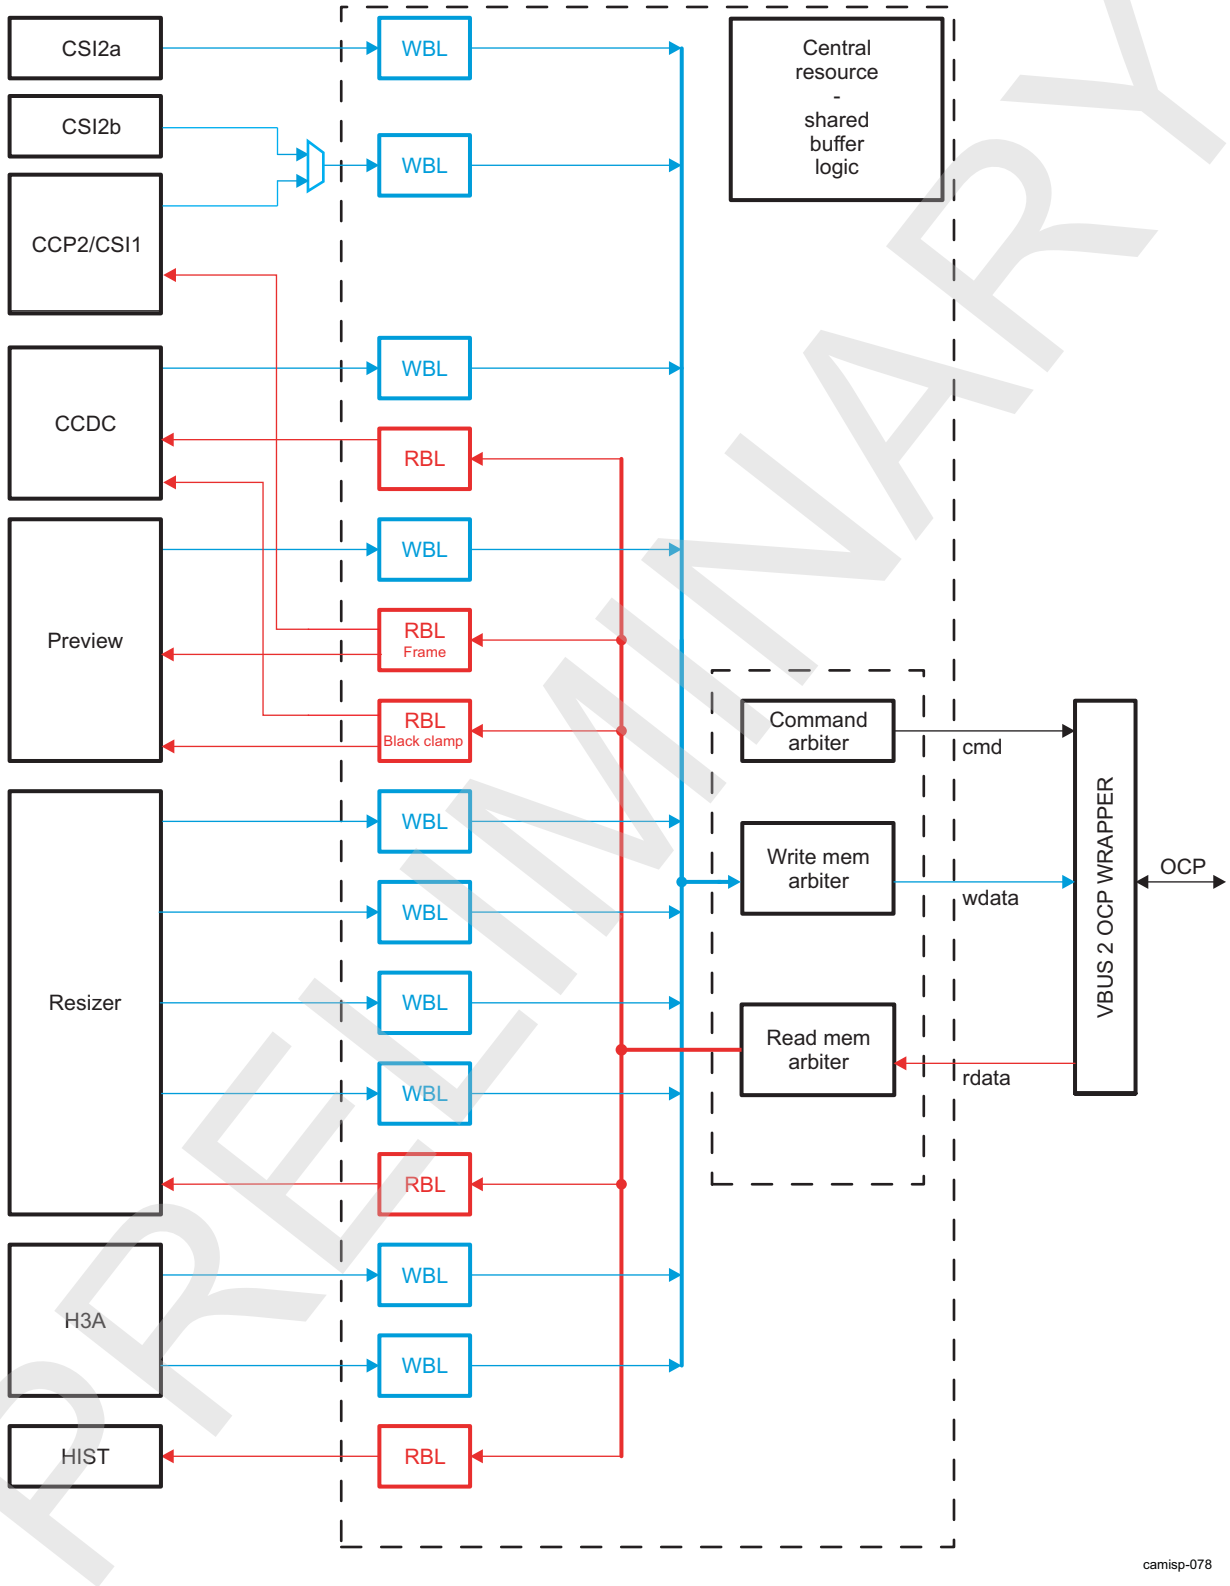
The central-resource SBL performs the following functions:

- Interface to the CCDC module:
  - Collects output data from the CCDC in the write buffer (1 port)
  - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
  - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the CSI2A, CSI2C, and CSI1/CCP2B receivers:
  - Collects output from CSI2A in the write buffer (1 port)
  - Collects output from CSI1/CCP2B and CSI2C in the write buffer (1 port)
  - Transfer input data to the CSI1/CCP2B from the read buffer. This port is shared with the PREVIEW module input data read port.
- Interface to the preview module:
  - Collects output data from the preview engine in the write buffer (1 port)
  - Transfer input data to the PREVIEW engine from the read buffer (1 ports). This port is shared with CSI1/CCP2B data read port.
  - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
  - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
  - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
  - Collects output data from the resizer in the write buffer (4 ports)
  - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

6.4.9.1 Camera ISP Shared Buffer Logic Block Diagram

Figure 6-97 shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 6-97. Camera ISP Shared Buffer Logic Block Diagram



NOTE: Red = Reads; Blue = Writes

CAUTION

Because some of the read ports are shared, software must enable the modules that will use the shared read port. For more information, see Section 6.4.9.2.3,*Camera ISP Shared Buffer Logic Read Buffer Logic (RBL) and Read Buffer*.

6.4.9.2 Camera ISP Shared Buffer Logic Functional Operations

6.4.9.2.1 Camera ISP Shared Buffer Logic Parameters

Table 6-47 summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

Table 6-47. Camera ISP Shared Buffer Logic Fixed Parameters

Port	Port Direction	Port Priority	Buffer Size Bytes	Description
CSI2A	WRITE	P3	1024 = 4DUs	CSI2A output port
CSI1/CCP2B and CSI2C	WRITE	P2	1024 = 4DUs	CSI1/CCP2B output port or CSI2C output port
CCDC	WRITE	P4	1024 = 4DUs	CCDC output port
	READ	P1	512 = 2DUs	CCDC fault pixel correction input port
PREVIEW	WRITE	P9	1024 = 4DUs	PREVIEW output port
	READ	P13	1024 = 4DUs	PREVIEW input port CSI1/CCP2B data input port
	READ	P0	1024 = 4DUs	PREVIEW dark-frame input port CCDC lens-shading compensation input port
RESIZER	WRITE	P5	1024 = 4DUs	RESIZER output line 1 port
	WRITE	P6	1024 = 4DUs	RESIZER output line 2 port
	WRITE	P7	1024 = 4DUs	RESIZER output line 3 port
	WRITE	P8	1024 = 4DUs	RESIZER output line 4 port
	READ	P12	1024 = 4DUs	RESIZER input port
H3A	WRITE	P10	512 = 2DUs	H3A output - AF port
	WRITE	P11	512 = 2DUs	H3A output - AE/AWB port
HIST	READ	P14	512 = 2DUs	HIST input port

6.4.9.2.2 Camera ISP Shared Buffer Logic Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
  - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
  - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is issued.

– An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is issued.

6.4.9.2.3 Camera ISP Shared Buffer Logic Read Buffer Logic (RBL) and Read Buffer

The central resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input
- Between the PREVIEW module and the CSI1/CCP2B module data read input

They can only be used by one module at a given time because there is no arbitration mechanism. Software must enable only one of the two possible features attached to a port and to select the correct multiplexer configuration using the ISP_CTRL [27] SBL_SHARED_RPORTA and ISP_CTRL [28] SBL_SHARED_RPORTB registers.

6.4.9.2.4 Camera ISP Shared Buffer Logic Arbitration

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

NOTE: The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

6.4.9.3 Camera ISP Shared Buffer Logic Memories

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules 256 x 128 bits.
- WRITE BUFFER 0: Used only by the resizer module 256 x 128 bits.
- WRITE BUFFER 1: Shared by all modules except RESIZER 256 x 128 bits.

6.4.9.4 Camera ISP Shared Buffer Logic Debug Registers

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
  - Individual module register command number. For modules with 2 individual requesters, this field displays either 0 or 1. For modules with 4 individual requesters, this field displays 0, 1, 2, or 3.
  - Source or destination module
  - Data-flow direction
  - Valid bit
- 52 individual module request registers (read or write information). Each register provides information

about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

Table 6-48. Camera ISP Shared Buffer Logic Number of Request Registers

Port	RD/WR	Nb Request Registers	Description
CSI2A	WRITE	4 WR request registers	CSI2A output
CSI1/CCP2B and CSI2C	WRITE	4 WR request registers	CSI1/CCP2B or CSI2C output
CCDC	WRITE	4 WR request registers	CCDC output
	READ	2 RD request registers	CCDC fault pixel correction input
PREVIEW	WRITE	4 WR request registers	PREVIEW output
	READ	4 RD request registers	PREVIEW input
	READ	4 RD request registers	PREVIEW dark-frame input
RESIZER	WRITE	4 WR request registers	RESIZER output line 1
	WRITE	4 WR request registers	RESIZER output line 2
	WRITE	4 WR request registers	RESIZER output line 3
	WRITE	4 WR request registers	RESIZER output line 4
	READ	4 RD request registers	RESIZER input port
H3A	WRITE	2 WR request registers	H3A output - AF port
	WRITE	2 WR request registers	H3A output - AE/AWB port
HIST	READ	2 RD request registers	HIST input

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

6.4.10 Camera ISP Circular Buffer

The circular buffer (CBUFF) maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

NOTE: Addresses can be further translated by the MMU.

6.4.10.1 Camera ISP Circular Buffer Feature List

The features are listed below:

- Two independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space
- Maximum physical buffer size of 16x16M bytes:
  - Physical space is composed by 2,4,8 or 16 windows
  - Maximum allowed window size is 16M bytes
- Support for multiline write patterns

  - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Memory fragmentation support for CBUFF0
- VRFB context grouping support
- Strong error detection mechanisms
- Buffer addresses are 64-bit aligned, but window fill level managing is byte accurate.
- Read and write accesses are supported.
- Bandwidth Control Feedback loop connected to the CSI1/CCP2B receiver flexible input

6.4.10.2 Camera ISP Circular Buffer Interrupts

All events generated (see Table 6-16 for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the ISP_IRQ0ENABLE [21] CBUFF_IRQ bit or to IVA2.2 by enabling the ISP_IRQ1ENABLE [21] CBUFF_IRQ bit.

6.4.10.3 Camera ISP Circular Buffer Functional Description

The CBUFF module maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical uses of the module.

6.4.10.3.1 Camera ISP Circular Buffer Bandwidth Control Feedback Loop

The bandwidth control feedback (BCF) feature can be used in memory to memory operation when the camera ISP reads data through the CSIb receivers flexible input.

At a given time a certain number of physical buffers are available for the processor. Depending, if the circular buffer is configured in read or write mode, the processor can, respectively, write or read those physical buffers.

When the number of physical buffers to be processed by the processor increases, the number of physical buffers available to the camera ISP decreases. When the number of physical buffers available for the camera ISP becomes too low, the corresponding BCF signal is asserted. This signal can be used to stall the data read flow.

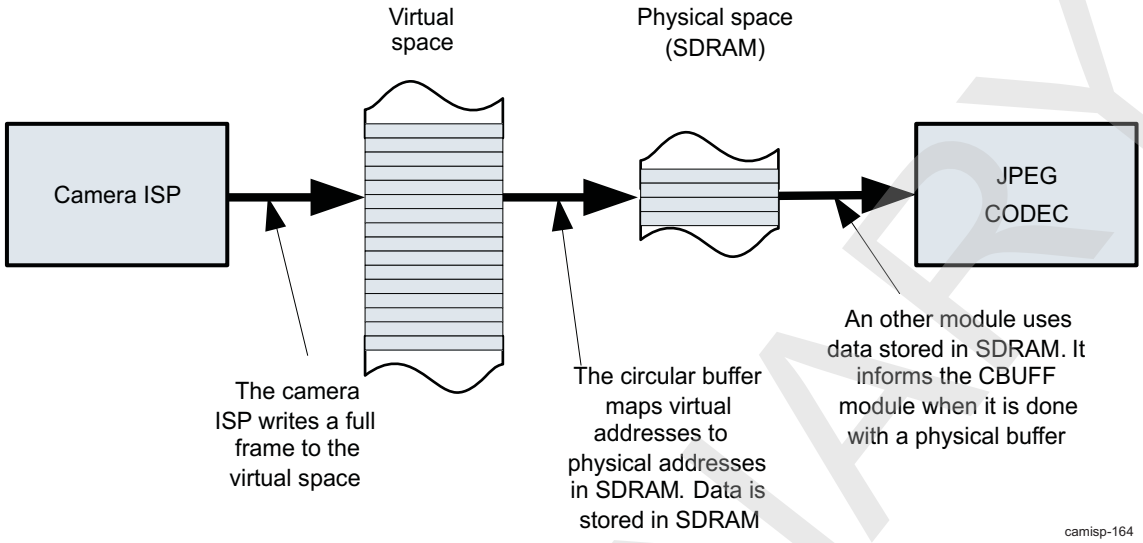
The camera ISP supports two mechanisms to reduce the processing speed in memory to memory operation:

- Add a fixed delay between memory read requests. Delays can be added:
  - At SBL level for all image data read ports (histogram, preview, CSI1/CCP2B and resizer)
  - At CSI1/CCP2B module level by slowing down the video port clock
- Stall memory reads based on the level of the circular buffer. That is the purpose of the BCF feature described in this section.

6.4.10.3.1.1 Camera ISP Circular Buffer Single Slice Mode

The camera ISP writes data with an incremental addressing scheme to the virtual space. The physical buffer is smaller than the virtual space. Therefore, the physical buffer locations is read or written multiple times. See Figure 6-98.

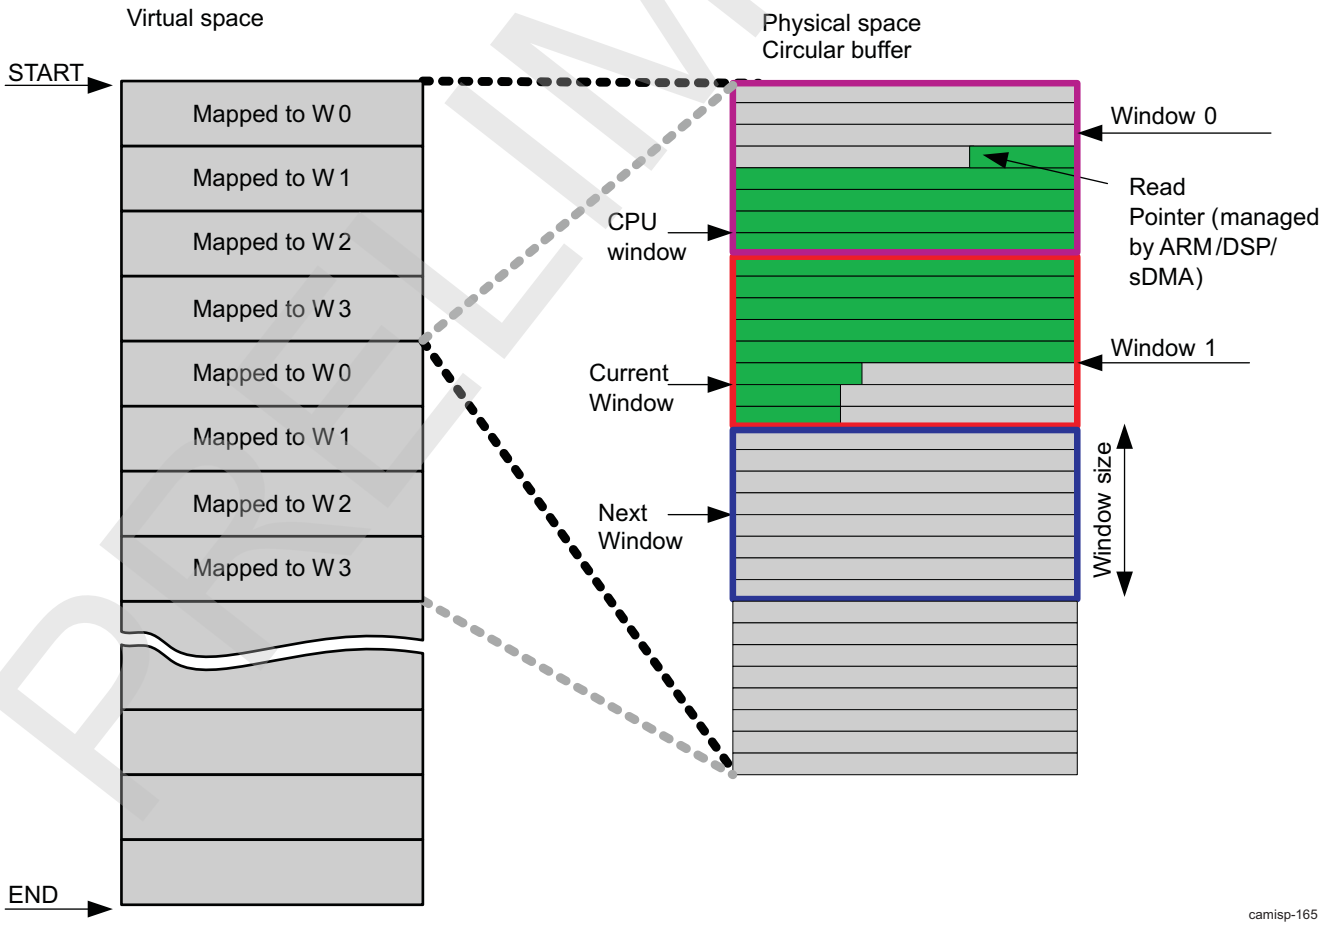
Figure 6-98. Camera ISP Circular Buffer Single Slice Buffer (Write Mode)



Physically, this circular buffer is typically in the SDRAM. The virtual space is defined by a start and an end address. The physical buffer is defined by a start address, a window size, and a window count. It is contiguous in memory.

Figure 6-99 shows the buffer organization for a 4-window buffer.

Figure 6-99. Camera ISP Circular Buffer Single Slice Buffer Example (Write Mode)



The CBUFF module can manage two independent circular buffers in single slice mode.

In case of memory-to-memory operation, the module using the data (that is, JPEG CODEC) written by the ISP into the circular buffer may be slower than the camera ISP. That is especially the case when the resizer is used for upscaling.

In this section, it is assumed that the data to be read by the camera ISP is a full frame completely present in physical memory. Sliced buffer capability is only used the buffer data at the output of the camera ISP. Therefore, the circular buffer is configured in write mode.

The basic idea is to stall the read data flow at CSIb flexible input level. This is done by blocking the response phase of the CSIb interconnect read master port. Blocking the response phase rather than the request phase allows data prefetch at SBL level.

When the count of full windows is greater than or equal to the value defined in the CBUFFx_CTRL[7:4] BCF register, the data flow between the SBL buffer and the CSI1/CCP2B data read port is stalled. Data transfers resume when the full window count falls below the defined limit.

Stalling the data flow at this level does not prevent the SBL from fetching data until its buffers are full. Therefore, when data transfer resumes, data are available quickly at the CSI1/CCP2B read port level, and ISP processing can resume.

Due to SBL buffering, some data may be sent out to the circular buffer when the stall command is activated. Firmware must allocate enough space in the circular buffer to avoid an overflow. The amount of buffered data depends on the ISP configuration:

- The camera ISP Video processing hardware can contain up to 10 pixels that are sent to the SBL after stall control is activated.
- The SBL can store up to four DUs at the output of the PREVIEW module. Therefore, when the circular buffer is filled from the PREVIEW module there must be enough space to store the extra 1K byte of data.
- The data path between the resizer and preview module goes though the SBL and data is internally buffered. The SBL can buffer up to 4 DUs between the PREVIEW and RESIZER module. In other words, when the input of the PREVIEW module is stalled, the RESIZER receives up to 2K bytes before it stalls.
- The SBL can store up to four DUs for each of the RESIZERs write ports. The count of ports used by the resizer depends on the vertical scaling factor; it uses ceil(vscale) ports. Each port writes into one image line and can buffer up to 1K byte.
- Depending on the resizing factor, the next write window may already contain up to three full video lines.

The largest amount of buffering is required when all of the following occur:

- The PREVIEW module is used.
- The RESIZER is used with a rescaling factor of 4x in the horizontal and vertical direction.
- The window size is not a multiple of the vertical up scaling factor.

Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use:

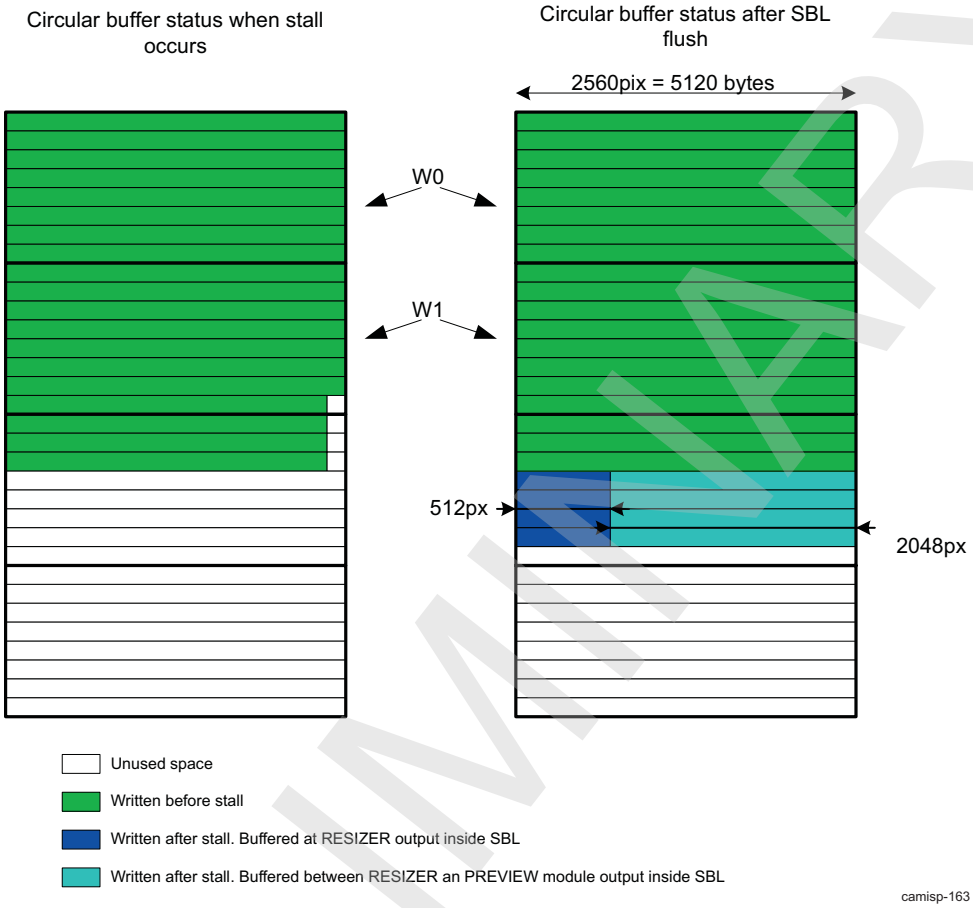
ThIs example shows how to calculate the minimum required window count when this feature is used.

It is assumed that the camera ISP reads a VGA RAW8 image from memory, processes it in the preview,and scales it up to 5M pix (2560x1920). The circular buffer is used for temporary storage between the JPEG CODEC and the camera ISP. Each window is configured to contain 8 video lines and the stall command is issued when at least two windows of the circular buffer are full.

Because the circular buffer window size is a multiple of the vertical upscaling factor, the next write window is empty when the stall command is issued. However, up to 1K byte = 512 pixels are stored for each write port of the resizer. This data is written as a 512x4 pixel bloc to the circular buffer by the SBL. Between the PREVIEW and RESIZER up to 1kbyte = 512 pixels are stored. This data expands to a block of 512x4x4 pixels written to the circular buffer by the SBL. In other words, up to 7 lines of the circular buffer may be filled after the stall command is issued. A minimum of four windows must be allocated to avoid an overflow of the circular buffer.

Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use: (continued)

Figure 6-100. Camera ISP Circular Buffer Control Feedback Loop Example



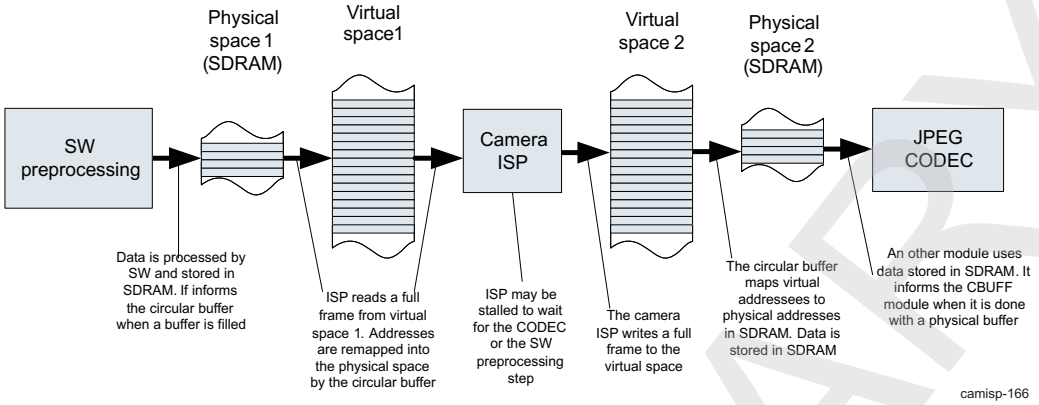
The CODEC reads data from the circular buffer and flag windows as done. In this example, the stall command is released when the CODEC has completed processing W0 and W1. The camera ISP resumes writing into W3.

NOTE: Software can control the minimum full window count to issue the stall command using the CBUFFx_CTRL[7:4] BCF register. Setting this value to 1 or 2 in this example may negatively affect the performance, because only up to two or three windows can be used.

6.4.10.3.1.2 Camera ISP Circular Buffer Extended Slice Mode

In extended slice mode, both circular buffers managed by the CBUFF module are used together. One provides address translation for the read data flow, and the other for a write data flow.

Figure 6-101. Camera ISP Circular Buffer Extended Slice Buffer Example



The camera ISP prefetches data and buffers it in the SBL. The CSI1/CCP2B flexible input pre-buffers up to 1K byte of data. In other words, the stall control for the CSI1/CCP2B interconnect read master port must be triggered in advance. Otherwise, the camera ISP may prefetch invalid data.

The last moment when the CSI1/CCP2B interconnect read master port can be safely stalled is when the physical read buffer still contains 1K byte of valid data. The camera ISP may or may not then read the remaining data into its internal SBL buffer.

The minimum amount of buffered data depends on the circular buffer configuration and the used data format.

When the processor filling the read buffer has no more data to write, the BCF feature must be disabled (clear ISP_CTRL [23:22] CBUFF0_BCF_CTRL or ISP_CTRL[25:24] CBUFF1_BCF_CTRL) for the CBUFF attached to the read data flow. This allows the camera ISP to prefetch the remaining data from the buffer without stalling.

6.4.10.3.1.3 Camera ISP Circular Buffer Fragmentation Support

This mode is available only for context 0 and CBUFF0. The mapped physical space does not need to be contiguous in memory.

NOTE: Software must ensure proper configuration of the CBUFF0 specific fragmentation support feature. Thus, the CBUFFx_ADDRy register must be configured correctly even if functionality was not initially required when data was accepted from ISP.

Software defines the location of each physical window using CBUFF0_ADDR0 through CBUFF0_ADDR15 (see CBUFFx_ADDRy). Figure 6-102 shows the fragmentation support.

Figure 6-102. Camera ISP Circular Buffer Fragmentation Support

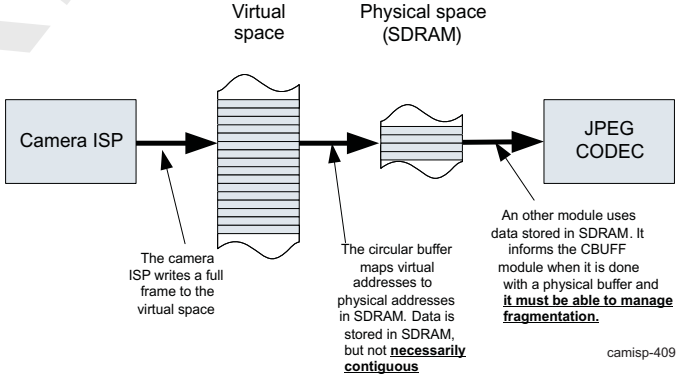


Table 6-49 provides the physical address of physical windows 0 to 15 for fragmentation functionality.

Table 6-49. Camera ISP Circular Buffer Fragmentation Support Physical Window Addresses

Physical Window	Fragmentation ON Register
0	CBUFF0_ADDR0
1	CBUFF0_ADDR1
2	CBUFF0_ADDR2
3	CBUFF0_ADDR3
4	CBUFF0_ADDR4
5	CBUFF0_ADDR5
6	CBUFF0_ADDR6
7	CBUFF0_ADDR7
8	CBUFF0_ADDR8
9	CBUFF0_ADDR9
10	CBUFF0_ADDR10
11	CBUFF0_ADDR11
12	CBUFF0_ADDR12
13	CBUFF0_ADDR13
14	CBUFF0_ADDR14
15	CBUFF0_ADDR15

6.4.10.3.1.4 Camera ISP Circular Buffer VRFB Context Grouping

The VRFB is part of the SMS module and provides support for image rotation by writing the data into SDRAM and reading it back. The VRFB can rotate frames of up to 2k * 2k pixels per context. That is sufficient to rotate the following image sizes

Table 6-50. Camera ISP Circular Buffer VRFB Maximum Supported Frame Size

Frame size	Aspect ratio
3.1 Mega Pixel	4/3
2.8 Mega Pixel	3/2
2.3 Mega Pixel	16/9

The CBUFF module can optionally perform address translation to group 4 contexts together. This extends the maximum frame size than can be rotated to the following:

Table 6-51. Camera ISP Circular Buffer VRFB Extended Supported Frame Size

Frame size	Aspect ratio
12.5 Mega Pixel	4/3
11.1 Mega Pixel	3/2
9.4 Mega Pixel	16/9

NOTE: VRFB context grouping is a standalone feature. It can not be combined with circular buffering or fragmentation.

The VRFB supports a total of 12 contexts. The CBUFF VRFB context grouping feature groups 4 contexts together to provide a larger virtual frame buffer. CBUFF can handle up to 3 groups or 4 VRFB contexts each.

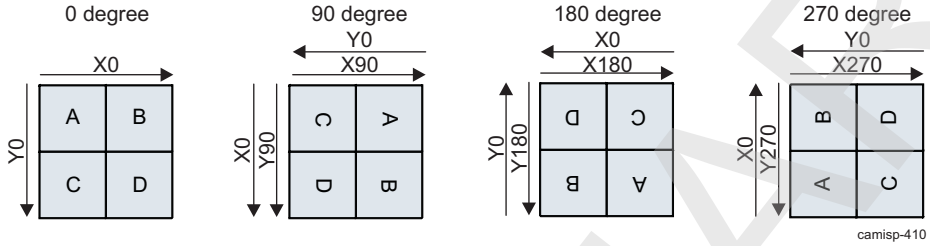
The software chooses which VRFB contexts to use by defining the base address of the 1st of the 4 contexts using the CBUFF_VRFB_CTRL.BASEx register (x=0, 1 or 2). Software must ensure that translated regions don't overlap.

Software also needs to define the data width (8, 16 or 32-bits) and the orientation (0, 90, 180 or 270 degrees) using the CBUFF_VRFB_CTRL.WIDTHx and CBUFF_VRFB_CTRL.ORIENTATIONx registers.

Translation is enabled by setting the CBUFF_VRFB_CTRL.ENABLEx bit. Software shall not change the translation configuration or enable/disable the translation while there is active traffic from ISP interface input port in the translated region (CBUFF_VRFB_CTRL.BASEx*256 Mega Bytes to CBUFF_VRFB_CTRL.BASEx+1)*256 Mega Bytes).

Figure 6-103 shows how the "large" virtual frame buffer seen in the address map of ISP interface input port is mapped to 4 "small" virtual frames accesses through interface output port.

Figure 6-103. Camera ISP Circular VRFB Buffer Performed Translation



6.4.10.3.2 Camera ISP Circular Buffer Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages two circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

Table 6-52. Camera ISP Circular Buffer Internal Variables

Quantity	Description
CWx	Current window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS[11:8] CW register.
NWx	Next window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS[19:16] NW register.
CPUWx	Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the CBUFFx_STATUS[3:0] CPUW register.
FCOx	Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by software.
OFFSETy	This is an internal quantity that cannot be accessed by software. y = 0: Address offset used when the current window of buffer 0 is accessed y = 1: Address offset used when the next window of buffer 0 is accessed y = 2: Address offset used when the current window of buffer 1 is accessed y = 3: Address offset used when the next window of buffer 1 is accessed
LEVELy	This is an internal quantity that cannot be accessed by software. y = 0: Amount of data, in bytes, read or written in the current window of buffer 0 y = 1: Amount of data, in bytes, read or written in the next window of buffer 0 y = 2: Amount of data, in bytes, read or written in the current window of buffer 1 y = 3: Amount of data, in bytes, read or written in the next window of buffer 1

6.4.10.3.2.1 Camera ISP Circular Buffer Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the CBUFF_IRQSTATUS register. Table 6-53 shows the internal state after reset.

Table 6-53. Camera ISP Circular Buffer Internal State After Reset

Quantity	Description
CWx	0
NWx	1

Table 6-53. Camera ISP Circular Buffer Internal State After Reset (continued)

Quantity	Description
CPUWx	0
FCOx	CBUFFx_START
OFFSET0	0
OFSFET1	0
OFFSET2,3	0
LEVELy	0

6.4.10.3.2.2 Camera ISP Circular Buffer Access Identification

For each access to the virtual space, the CBUFF module first checks the address (ADDR) to classify the transaction into one of the categories listed in Table 6-54.

Table 6-54. Camera ISP Circular Buffer Address Identification

ID	Label	Condition
0	CW_CBUFF0	CBUFFx_CTRL[0] ENABLE = 1 and ADDR>=FCO0 and ADDRFCO0 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
1	NW_CBUFF0	CBUFFx_CTRL[0] ENABLE=1 (x = 0) and ADDR>=FCO0 + CBUFFx_WINDOWSIZE and ADDRFCO0 + 2*CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
2	CW_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>=FCO1 and ADDRFCO1 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
3	NW_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>=FCO1 + CBUFFx_WINDOWSIZE and ADDRFCO1 + 2*CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
4	ERR_CBUFF0	CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 0)
5	ERR_CBUFF1	CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END (x = 1)
6	TRANSPARENT	Always true

Lower IDs correspond to higher priorities in case multiple conditions are true. For example, when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW_CBUFF0 and ERR_CBUFF0 are true. The final category is CW_CBUFF0, because it has a higher priority.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR_CBUFF0 and ERR_CBUFF1: The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the CBUFF_IRQSTATUS[1] IRQ_CBUFF0_INVALID bit (or CBUFF_IRQSTATUS[4] IRQ_CBUFF1_INVALID). When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between CBUFFx_START and CBUFFx_END (x = 0) is not transmitted to the interconnect. There are two ways to leave the error state:
  - Hardware reset
  - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state

  Accesses outside of the virtual space from the circular buffer in error state are not affected.
- CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 and NW_CBUFF1: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the

current mode (read or write). Otherwise, an IRQ_CBUFFx_INVALID event is set and CBUFFx goes into the error state.

6.4.10.3.2.3 Camera ISP Circular Buffer Address Translation

An offset is selected depending on the access category (see Section 6.4.10.3.2.1, *Camera ISP Circular Buffer Startup*) and the internal state of the accessed buffer. Table 6-55 lists possible cases.

Table 6-55. Camera ISP Circular Buffer Address Translation

Condition	Address Translation
CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END and CBUFF0 in error state (x = 0)	Access cancelled
CBUFFx_CTRL[0] ENABLE=1 and ADDR>= CBUFFx_START and ADDR= CBUFFx_END and CBUFF1 in error state (x = 1)	Access cancelled
Category = CW_CBUFF0	ADDROUT = ADDRIN-OFFSET0
Category = NW_CBUFF0	ADDROUT = ADDRIN-OFFSET1
Category = CW_CBUFF1	ADDROUT = ADDRIN-OFFSET2
Category = NW_CBUFF1	ADDROUT = ADDRIN-OFFSET3
Category = ERR_CBUFF0	Access cancelled
Category = ERR_CBUFF1	Access cancelled
Category = TRANSPARENT	ADDROUT = ADDRIN

6.4.10.3.2.4 Camera ISP Circular Buffer Window Fill Level

Each time an access is performed into an active window (CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 or NW_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. Table 6-56 shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

Table 6-56. Camera ISP Circular Buffer Window Level Increment

BYTEEN	LEVELy Increment	Comment
0x00	+0	No access
0x01	+1	8 bit access
0x02	+1	8 bit access
0x03	+2	16 bit access
...	...	...
0x07	+3	24 bit access
...	...	...
0x0F	+4	32 bit access
...	...	...
0xF0	+4	32 bit access
...	...	...
0xFF	+8	64 bit access

The window level is compared to CBUFFx_THRESHOLD. As listed in Table 6-57, the following situations may occur:

Table 6-57. Camera ISP Circular Buffer Window Level Comparison

Condition	Description
LEVEL0>= CBUFFx_THRESHOLD (x = 0)	Current window of buffer 0 full. Internal window indexes, levels, and offsets are updated.

Table 6-57. Camera ISP Circular Buffer Window Level Comparison (continued)

Condition	Description
LEVEL1>= CBUFFx_THRESHOLD (x = 0)	Next window of buffer 0 full. An IRQ_CBUFF0_INVALID error event is set and CBUFF0 enters the error state.
LEVEL2>= CBUFFx_THRESHOLD (x = 1)	Current window of buffer 1 full
LEVEL3>= CBUFFx_THRESHOLD (x = 1)	Next window of buffer 1 full. An IRQ_CBUFF1_INVALID error event is set and CBUFF1 enters the error state.

6.4.10.3.2.5 Camera ISP Circular Buffer Window Pointer and Offset Update

When the current window of a circular buffer (CBUFFx, x = 0 or 1) is full:

- The "next window" becomes the "current window"
  - CWx <- NW
  - LEVEL(2*x) <- LEVEL (2*x+1)
  - OFFSET(2*x) <- OFFSET(2*x+1)
  - FCOx <- FCOx + CBUFFx_WINDOWSIZE
- A new "next window" if opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
  - NW <- (NW+1) modulo WC
  - LEVEL(2*x+1) <- 0
  - VPA <- VPA + CBUFFx_WINDOWSIZE
  - When fragmentation used for CBUFF0:
    - OFFSET(2*x+1) <- OFFSET(2*x+1) + VPA * CBUFFx_WINDOWSIZE - CBUFF0_ADDR[CBUFF0_STATUS[WA]]
  - When the "next window" is moved from the last buffer to the first:
    - OFFSET(2*x+1) <- OFFSET(2*x+1) + WCx * CBUFFx_WINDOWSIZE

NOTE: WC is the window count defined by the CBUFFx_CTRL[9:8] WCOUNT register.

6.4.10.3.3 Camera ISP Circular Buffer CPU Interaction

The CBUFF module sets an IRQ_CBUFFx_READY event to inform the CPU that it can access the CPUx window in the physical buffer. The CBUFF module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the CPUWx window by writing the CBUFFx_CTRL[2] DONE bit. This increments the CPU window index CPUWx by one modulo the window count.

The behavior depends on whether read or write mode has been selected using the CBUFFx_CTRL[1] RWMODE bit.

NOTE: Some details of this feature are not available in the public domain.

6.4.11 Camera ISP MMU Logic

6.4.11.1 Camera ISP MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU.MMU_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

6.4.11.2 Camera ISP MMU Functional Description

For a detailed description of the MMU, see Chapter 15, *Memory Management Units*.

NOTE: In the camera ISP MMU, the endianess feature is available for write, but conversion for read is not possible.

6.5 Camera ISP Basic Programming Model

6.5.1 Programming the ISP PRCM Clocks Configuration

The camera subsystem clocks are provided by the PRCM module. The software must set the PRCM registers as follows:

1. To set the cam_mclk:
   The DPLL4_ALWON_FCLKOUT clock is sourced by the system clock (SYS_CLK) at a *X* frequency and calculated as follows:
   DPLL4_ALWON_FLCKOUT = [SYS_CLK (*X* frequency) x 2 x M (0xE1)] / [N (0x9) + 1]
   cam_mclk = DPLL4_ALWON_FCLKOUT / CLKSEL_CAM (4)
   PRCM.CM_CLKSEL_CAM.CLKSEL_CAM = x
2. Enable the cam_fclk clock:
   PRCM.CM_FLCKEN_CAM [0] EN_CAM = 0x1
3. Enable the cam_iclk clock:
   PRCM.CM_ICLKEN_CAM [0] EN_CAM = 0x1

Table 6-58 lists the registers to configure the camera subsystem clock configuration step.

Table 6-58. Camera ISP PRCM Registers Settings

Register Name	Address	Value Description
PRCM.CM_CLKSEL_CAM	0x4800 4F40	DPLL4 divisor set to 0x4
PRCM.CM_FLCKEN_CAM	0x4800 4F00	Enable CAM_FCLK
PRCM.CM_ICLKEN_CAM	0x4800 4F10	Enable CAM_ICLK

6.5.2 Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY

6.5.2.1 Camera ISP CSIPHY Initialization for Work With CSI2 Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to receive signals/data from the CSIPHY:
   (a) Configure all necessary CSI2 registers:
   (i) Set CSI2_COMPLEXIO_CFG1[10:8] DATA2_POSITION.
   (ii) Set CSI2_COMPLEXIO_CFG1[6:4] DATA1_POSITION.
   (iii) Set CSI2_COMPLEXIO_CFG1[2:0] CLOCK_POSITION.
   (iv) Set CONTROL_CAMERA_PHY_CTRL[1:0] R_CONTROL_CAMERA2_PHY_CAMMODE or CONTROL_CAMERA_PHY_CTRL[3:2] R_CONTROL_CAMERA1_PHY_CAMMODE.

CAUTION

This must be done before the CSIPHY is active.

2. CSIPHY and link initialization sequence:
   (a) Deassert the CSIPHY reset:
      (i) Set CSI2_COMPLEXIO_CFG1[30] RESET_CTRL to 0x1.
   (b) The following registers can be set only after deasserting the CSIPHY reset, and before asserting the ForceRxMode signal:
   - CSIPHY_REG0
   - CSIPHY_REG1
   - CSIPHY_REG2

   (c) Assert the ForceRxMode signal:
      (i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x1.
   (d) Connect the pulldown on the link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):
   - For CSIPHY1: Pull down on signals through padconf registers:
     - cam_d6:
       - CONTROL_PADCONF_CAM_D5[24] INPUTENABLE1 = 0x1
       - CONTROL_PADCONF_CAM_D5[20] PULLTYPESELECT1 = 0x0
       - CONTROL_PADCONF_CAM_D5[19] PULLUDENABLE1 = 0x1
     - cam_d7:
       - CONTROL_PADCONF_CAM_D7[8] INPUTENABLE0 = 0x1
       - CONTROL_PADCONF_CAM_D7[4] PULLTYPESELECT0 = 0x0
       - CONTROL_PADCONF_CAM_D7[3] PULLUDENABLE0 = 0x1
     - cam_d8:
       - CONTROL_PADCONF_CAM_D7[24] INPUTENABLE1 = 0x1
       - CONTROL_PADCONF_CAM_D7[20] PULLTYPESELECT1 = 0x0
       - CONTROL_PADCONF_CAM_D7[19] PULLUDENABLE1 = 0x1
     - cam_d9:
       - CONTROL_PADCONF_CAM_D9[8] INPUTENABLE0 = 0x1
       - CONTROL_PADCONF_CAM_D9[4] PULLTYPESELECT0 = 0x0
       - CONTROL_PADCONF_CAM_D9[3] PULLUDENABLE0 = 0x1
   - For CSIPHY2: Pull down on signals through padconf registers:
     - cam_d0:
       - CONTROL_PADCONF_CAM_FLD[24] INPUTENABLE1 = 0x1
       - CONTROL_PADCONF_CAM_FLD[20] PULLTYPESELECT1 = 0x0
       - CONTROL_PADCONF_CAM_FLD[19] PULLUDENABLE1 = 0x1
     - cam_d1:
       - CONTROL_PADCONF_CAM_D1[8] INPUTENABLE0 = 0x1
       - CONTROL_PADCONF_CAM_D1[4] PULLTYPESELECT0 = 0x0
       - CONTROL_PADCONF_CAM_D1[3] PULLUDENABLE0 = 0x1
     - csi2_dx0:
       - CONTROL_PADCONF_CSI2_DX0[8] INPUTENABLE0 = 0x1
       - CONTROL_PADCONF_CSI2_DX0[4] PULLTYPESELECT0 = 0x0
       - CONTROL_PADCONF_CSI2_DX0[3] PULLUDENABLE0 = 0x1
     - csi2_dy0:
       - CONTROL_PADCONF_CSI2_DX0[24] INPUTENABLE1 = 0x1
       - CONTROL_PADCONF_CSI2_DX0[20] PULLTYPESELECT1 = 0x0
       - CONTROL_PADCONF_CSI2_DX0[19] PULLUDENABLE1 = 0x1
     - csi2_dx1:
       - CONTROL_PADCONF_CSI2_DX1[8] INPUTENABLE0 = 0x1
       - CONTROL_PADCONF_CSI2_DX1[4] PULLTYPESELECT0 = 0x0
       - CONTROL_PADCONF_CSI2_DX1[3] PULLUDENABLE0 = 0x1
     - csi2_dy1:

- CONTROL_PADCONF_CSI2_DX1[24] INPUTENABLE1 = 0x1
- CONTROL_PADCONF_CSI2_DX1[20] PULLTYPESELECT1 = 0x0
- CONTROL_PADCONF_CSI2_DX1[19] PULLUDENABLE1 = 0x1

(e) Power up the CSIPHY:

(i) Set CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD to 0x1.

(f) Check that the state status reaches the ON state:

- CSI2_COMPLEXIO_CFG1[26:25] PWR_STATUS = 0x1

(g) Wait for STOPSTATE = 1 (for all enabled lane modules):

(i) The timer is set through the CSI2_TIMING[14:0] bit field. The reset value can be kept.

(ii) Wait until CSI2_TIMING[15] FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.

(h) Release PIPD* (= 1):

- For CSIPHY1: Pull up on signals through padconf registers:
  - cam_d6:
    - CONTROL_PADCONF_CAM_D5[20] PULLTYPESELECT1 = 0x1
  - cam_d7:
    - CONTROL_PADCONF_CAM_D7[4] PULLTYPESELECT0 = 0x1
  - cam_d8:
    - CONTROL_PADCONF_CAM_D7[20] PULLTYPESELECT1 = 0x1
  - cam_d9:
    - CONTROL_PADCONF_CAM_D9[4] PULLTYPESELECT0 = 0x1
- For CSIPHY2: Pull up on signals through padconf registers:
  - cam_d0:
    - CONTROL_PADCONF_CAM_FLD[20] PULLTYPESELECT1 = 0x1
  - cam_d1:
    - CONTROL_PADCONF_CAM_D1[4] PULLTYPESELECT0 = 0x1
  - csi2_dx0:
    - CONTROL_PADCONF_CSI2_DX0[4] PULLTYPESELECT0 = 0x1
  - csi2_dy0:
    - CONTROL_PADCONF_CSI2_DX0[20] PULLTYPESELECT1 = 0x1
  - csi2_dx1:
    - CONTROL_PADCONF_CSI2_DX1[4] PULLTYPESELECT0 = 0x1
  - csi2_dy1:
    - CONTROL_PADCONF_CSI2_DX1[20] PULLTYPESELECT1 = 0x1

(i) The CSIPHY is initialized and ready/active in CSI2 mode.

6.5.2.2 Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI1/CCP2B receiver registers to receive signals/data from the CSIPHY:

(a) Configure all CSI1/CCP2B registers:

(i) Set CSI2_COMPLEXIO_CFG1[10:8] DATA2_POSITION.

CCP2 mode for work with CSIPHY1:

0x0: Not used/connected

CCP2 mode for work with CSIPHY2:

0x0: Not used/connected

(ii) Set CSI2_COMPLEXIO_CFG1[6:4] DATA1_POSITION.

CCP2 mode for work with CSIPHY1:

0x1: Data lane 1 is at position 2.

0x2: Data lane 1 is at position 1.

CCP2 mode for work with CSIPHY2:

0x1: Data lane 1 is at position 2.

0x2: Data lane 1 is at position 1.

(iii) Set CSI2_COMPLEXIO_CFG1[2:0] CLOCK_POSITION.

CCP2 mode for work with CSIPHY1:

0x1: Clock lane is at position 2.

0x5: Clock lane is at position 1.

CCP2 mode for work with CSIPHY2:

0x1: Clock lane is at position 2.

0x5: Clock lane is at position 1.

(iv) Set CONTROL_CAMERA_PHY_CTRL[1:0] R_CONTROL_CAMERA2_PHY_CAMMODE or CONTROL_CAMERA_PHY_CTRL[3:2] R_CONTROL_CAMERA1_PHY_CAMMODE.

CAUTION

This must be done before the CSIPHY is active.

(v) Set CONTROL_CAMERA_PHY_CTRL[4] R_CONTROL_CSI1_RX_SEL.

CAUTION

This must be done before the CSIPHY is active.

2. CSIPHY and link initialization sequence:

(a) Deassert the CSIPHY reset:

(i) Set CSI2_COMPLEXIO_CFG1[30] RESET_CTRL to 0x1.

(b) Assert the ForceRxMode signal:

(i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x1.

(c) Power up the CSIPHY:

(i) Set CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD to 0x1.

(d) Check that the state status reaches the ON state:

- CSI2_COMPLEXIO_CFG1[26:25] PWR_STATUS = 0x1.

(e) Release the ForceRxMode signal:

(i) Set CSI2_TIMING[15] FORCE_RX_MODE_IO1 to 0x0.

(f) CSIPHY is initialized and ready/active in CSI1/CCP2B mode.

6.5.3 Programming the CSI1/CCP2B Receiver

This section describes the programming model of the CSI1/CCP2B receiver.

6.5.3.1 Camera ISP CSI1/CCP2B Hardware Setup/Initialization

This section discusses the configuration of the CSI1/CCP2B receiver required before image capture can begin.

6.5.3.1.1 Camera ISP CSI1/CCP2B Reset Behavior

On hardware or software reset of the camera ISP, all registers in the CSI1/CCP2B receiver are reset to their reset values.

6.5.3.2 Camera ISP CSI1/CCP2B Event and Status Checking

When an event occurs, the corresponding bit in the CCP2_LC01_IRQSTATUS (or CCP2_LC23_IRQSTATUS) register is set. Each event can be individually masked using the CCP2_LC01_IRQENABLE register (CCP2_LC23_IRQENABLE). Masked events are not transmitted to the interrupt lane, but the CCP2_LC01_IRQSTATUS register (or CCP2_LC23_IRQSTATUS) is updated.

Events transmitted to the interrupt lane can be mapped to the ARM or DSP by unmasking the ISP_CSIB bit in the ISP_IRQxENABLE (x = 0, 1). Depending on whether the event is mapped to the ARM or DSP register, to clear an event, the following actions are required:

- Clear the event at the CSI1/CCP2B receiver level by writing 1 to the corresponding bit in the CCP2_LC01_IRQSTATUS register (or CCP2_LC23_IRQSTATUS).
- Clear the event at ISP level by writing 1 to the corresponding bit ISP_CSI1 in the ISP_IRQxENABLE (x = 0, 1) register.

6.5.3.3 Camera ISP CSI1/CCP2B Register Accessibility During Frame Processing

There are two types of register accesses in the CSI1/CCP2B receiver:

- Shadowed registers:
  - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
  - The shadowed registers are:
    - CCP2_LCx_CTRL
    - CCP2_LCx_CODE
    - CCP2_LCx_STAT_START
    - CCP2_LCx_STAT_SIZE
    - CCP2_LCx_SOF_ADDR
    - CCP2_LCx_EOF_ADDR
    - CCP2_LCx_DAT_SIZE
    - CCP2_LCx_DAT_PING_ADDR
    - CCP2_LCx_DAT_PONG_ADDR
    - CCP2_LCx_DAT_OFST
- Busy-locked registers:
  - These registers/fields must not be written if the module is busy.
  - All register fields not listed as shadowed are busy-writable registers.

6.5.3.4 Camera ISP CSI1/CCP2B Enable/Disable the Hardware

The CSI1/CCP2B receiver is globally controlled by the CCP2_CTRL register. The bit fields in this register must not be modified when the CSI1/CCP2B interface is active (except CCP2_CTRL [0] IF_EN):

- To activate the CSI1/CCP2B interface:
  - CCP2_CTRL [0] IF_EN = 0x1
  - Data acquisition starts on the following FSC synchronization code. Writing CCP2_CTRL [0] IF_EN = 0x1 resets the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.
- To disable the CSI1/CCP2B interface:
  - CCP2_CTRL [0] IF_EN = 0x0
  - The interface is disabled immediately if CCP2_CTRL [3] FRAME = 0x0.
  - If CCP2_CTRL [3] FRAME = 0x1 and CCP2_LCx_CTRL[19] CRC_EN = 0x0, the interface is disabled after the FEC synchronization code is received.
  - If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[19] CRC_EN = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received.
  - Before disabling the interface (IF_EN=0) it is advised to disable all active channels by writing CCP2_LCx_CTRL[0] CHAN_EN = 0x0. Otherwise, if IF_EN = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active

channels.

6.5.3.5 Camera ISP CSI1/CCP2B Select the Signaling Scheme

The CCP2_CTRL[1] PHY_SEL bit selects whether the data/strobe or data/clock signaling scheme is used. See Table 6-22 for the correct settings as a function of the image sensor class. Setting CCP2_CTRL [1] PHY_SEL = 0x1 has no effect if CCP2_CTRL [4] MODE = 0x0.

6.5.3.6 Camera ISP CSI1/CCP2B Control of the PHY

The CCP2_CTRL [2] IO_OUT_SEL bit selects the output mode of the CSI1/CCP2B recevier associated PHY(could be either CSIPHY1 or CSI2PHY2), which must be set to 1 for parallel only.

For information about initializing and configuring the CSIPHY that is associated with the CSI1/CCP2B receiver, see Section 6.5.2.2, *Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver.*

6.5.3.7 Camera ISP CSI1/CCP2B Select the Mode: MIPI® CSI1 or CCP2B

The CCP2_CTRL[4] MODE bit selects whether the CCP2B module works in MIPI® CSI1 or CCP2-compatible mode. Setting CCP2_CTRL[4] MODE = 0x0 disables the CCP2-specific features: data/strobe, CRC, logical channels, RAW6 and RAW7 data formats. The following bits have no effect when CCP2_CTRL[4] MODE = 0x0: CCP2_CTRL[1] PHY_SEL, CCP2_LCx_CTRL[19] CRC_EN, CCP2_LCx_CTRL[0] CHAN_EN (x = 1 to 3). Furthermore, CCP2_LCx_CTRL[7:2] FORMAT values 8, 9, 10, 12, 13, 14, 17, 18, 21, and 25 have no effect: no data are output. MIPI® CSI1 is the default mode of the module.

6.5.3.8 Camera ISP CSI1/CCP2B Burst Settings

The CCP2_CTRL[6:5] BURST bit field forces the burst behavior of the CSI1/CCP2B receiver. The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, and 8x 64 bits. The burst size must never exceed the output FIFO size. The output FIFO size can be read by reading the CCP2_GNQ[4:2] FIFODEPTH bit field.

6.5.3.9 Camera ISP CSI1/CCP2B Debug Mode

Use the CCP2_CTRL [7] DBG_EN bit to enable the debug mode:

- During debug mode, the input comes from the CCP2_DBG register, not from the CSI1/CCP2B physical interface. The full CSI1/CCP2B receiver functionality can be debugged in debug mode. Full 32-bit values must always be written to the CCP2_DBG register.
- The following bits have no effect during debug mode:
  - CCP2_CTRL [0] IF_EN
  - CCP2_CTRL [1] PHY_SEL
  - CCP2_CTRL [2] IO_OUT_SEL
- The following examples apply to the CCP2_DBG register:
  - Synchronization codes: CCP2_DBG = 0xFF000000
  - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write CCP2_DBG = 0x01234567 followed by CCP2_DBG = and 0x89abcdef CCP2_DBG = 0x76543210.

NOTE: Each write to the CCP2_DBG register sends a full 32-bit word through the CSI1/CCP2B receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x000000FF with BYTEEN = 0x1 (this write from the MPU subsystem informs that only 8 bits are written), the CSI1/CCP2B receiver pipeline gets 0x01234567 followed by 0x012345FF.

6.5.3.10 Camera ISP CSI1/CCP2B Video Port

- Set the video-port output frequency:

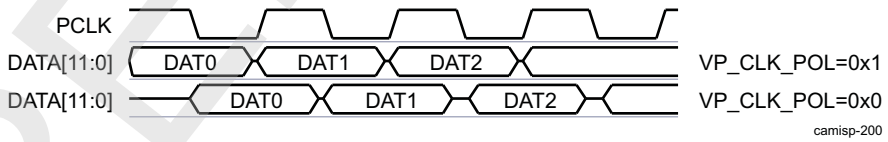
  - CCP2_CTRL [9:8] VP_OUT_CTRL
  - The video-port output frequency varies from CAM_ICLK to CAM_ICLK/4 MHz. CAM_ICLK is the CSI1/CCP2B receiver functional and interface clock. The reset value selects CAM_ICLK/2.
- CCP2_CTRL [11] VP_ONLY_EN:
  - Controls whether the video-port output is the only output interface enabled and applies for all channels.
  - When CCP2_CTRL [11] VP_ONLY_EN = 0x1, the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to video port and embedded data to interconnect).
    - The video port outputs the embedded data defined by the CCP2_LCx_STAT_START and CCP2_LCx_STAT_SIZE registers without decompression.
    - The video port outputs the pixel data defined by the CCP2_LCx_DAT_START and CCP2_LCx_DAT_SIZE registers.
  - The pixel data are decompressed according to the settings of the CCP2_LCx_CTRL [7:2] FORMAT bit field. Table 6-59 summarizes the behavior of the video port as a function of the CCP2_LCx_CTRL [7:2] FORMAT bit field.

Table 6-59. Camera ISP CSI1/CCP2B CCP2_LCx_CTRL[7:2] FORMAT and CCP2_CTRL[11] VP_ONLY_EN = 1 Settings

CCP2_LCx_CTRL [7:2] Format	Video-Port Behavior
YUV422 + VP or RAW8 + VP	The incoming data are 8 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 8 bits (DATA[7:0]). The pixel data are not decompressed. The pixel data are transmitted to the CCDC module on 8 bits (DATA[7:0]).
RAW12 + VP	The incoming data are 12 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are reconstructed in the receiver. The pixel data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are not decompressed.

- Control the video-port pixel clock polarity:
  - If CCP2_CTRL [12] VP_CLK_POL = 0x0, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge.
  - If CCP2_CTRL [12] VP_CLK_POL = 0x1, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock raising edge. The module connected to the VP samples the data on the pixel clock falling edge. Figure 6-104 shows the CCP2_CTRL .VP_CLK_POL settings.

Figure 6-104. Camera ISP CSI1/CCP2B CCP2_CTRL.VP_CLK_POL Settings



6.5.3.11 Camera ISP CSI1/CCP2B Logical Channels

The CCP2B receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all other logical channels. Logical channel LCx means LC0, LC1, LC2, or LC3.

All the registers in this section can be modified at any time. However, the modifications apply only from the start of the following frame.

6.5.3.12 Camera ISP CSI1/CCP2B Controls

The logical channel is controlled by the CCP2_LCx_CTRL register.

The logical channel is enabled by setting CCP2_LCx_CTRL[0] CHAN_EN = 0x1. By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the Video processing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface. Setting CCP2_LCx_CTRL[0] CHAN_EN (x=1), CCP2_LCx_CTRL[0] CHAN_EN (x=2), or CCP2_LCx_CTRL[0] CHAN_EN = 0x1 (x=3) has no effect if CCP2_CTRL[4] MODE = 0x0.

6.5.3.13 Camera ISP CSI1/CCP2B Region of Interest

The CCP2_LCx_CTRL[1] REGION_EN bit enables the region-of-interest feature (SOF lines, pixel data, and EOF lines):

- If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored.
- If disabled, all data in the frame are output. CCP2_LCx_CTRL[1] REGION_EN is set to 0x0 for a JPEG bitstream.

6.5.3.14 Camera ISP CSI1/CCP2B CRC

The CRC can be enabled or disabled with CCP2_LCx_CTRL[19] CRC_EN. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is LCx_CRC_IRQ. Setting CCP2_LCx_CTRL[19] CRC_EN = 0x1 has no effect if CCP2_CTRL[4] MODE = 0x0.

6.5.3.15 Camera ISP CSI1/CCP2B Destination Format

- Control the destination format:
  - The CSI1/CCP2B receiver reformats received data to store it in memory or to send it to the Videp processing hardware.
  - CCP2_LCx_CTRL[7:2] FORMAT controls destination-data format:
    - EXP8 = Data expansion to 8 bits, padding with zeros
    - EXP16 = Data expansion to 16 bits, padding with alpha or zeros CCP2_CTRL[15:8] ALPHA can be used to set an alpha value. For RGB444 + EXP16:
      - data_out[31:28]=ALPHA[3:0] and data_out[27:16]=RGB444
      - data_out[15:12]=ALPHA[3:0] and data_out[11:0]=RGB444
    - EXP32 = Data expansion to 32 bits, padding with alpha. CCP2_CTRL[15:8] ALPHA can be used to set an alpha value. For RGB888 + EXP32: data_out[31:24]=ALPHA[7:0] and data_out[23:0]=RGB888
    - FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
    - VP = Output to the Video processing hardware is enabled.

6.5.3.16 Camera ISP CSI1/CCP2B Frame Acquisition

- Program the number of frames that the CSI1/CCP2B receiver acquires:
  - CCP2_LCx_CTRL [31:24] COUNT
  - Writes to the COUNT bit field are controlled by the CCP2_LCx_CTRL [16] COUNT_UNLOCK bit.
  - If COUNT = 0x0, the counter is free-running; frame acquisition lasts until disabled by the programmer. It is the default value.
  - COUNT controls the number of frames to acquire. The values range between 1 and 255. The COUNT value is decremented after each frame received. The software can read this value to acquire the number of frames that remain to be acquired.

After the correct number of frames is received, acquisition is automatically disabled (CCP2_LCx_CTRL [0] CHAN_EN = 0x0) and the COUNT_IRQ interrupt is triggered. The programmer can reenable the acquisition by resetting CCP2_LCx_CTRL [0] CHAN_EN to 0x1.

CCP2_LCx_CTRL [17] PING_PONG indicates whether the PING address (CCP2_LCx_DAT_PING_ADDR) or PONG address (CCP2_LCx_DAT_PONG_ADDR was used to store

the pixel data of the last frame. After reset or after a 0-to-1 edge transition in CCP2_CTRL [0] IF_EN, the pixel data are written in the PING buffer and CCP2_LCx_CTRL [17] PING_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and CCP2_LCx_CTRL [17] PING_PONG = 0x0 (PING). CCP2_LCx_CTRL [17] PING_PONG toggles after every FEC synchronization code.

6.5.3.17 Camera ISP CSI1/CCP2B Synchronization Codes

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the CCP2B specification. Also, each logical channel is identified by a default identifier.

The CCP2_LCx_CODE register enables overwriting of the default values: CCP2_LCx_CODE [11:8] FSC, CCP2_LCx_CODE [15:12] FEC, CCP2_LCx_CODE [3:0] LSC, and CCP2_LCx_CODE [7:4] LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values should not be modified.

6.5.3.18 Camera ISP CSI1/CCP2B Status Data

The SOF and EOF status lines can be output to memory.

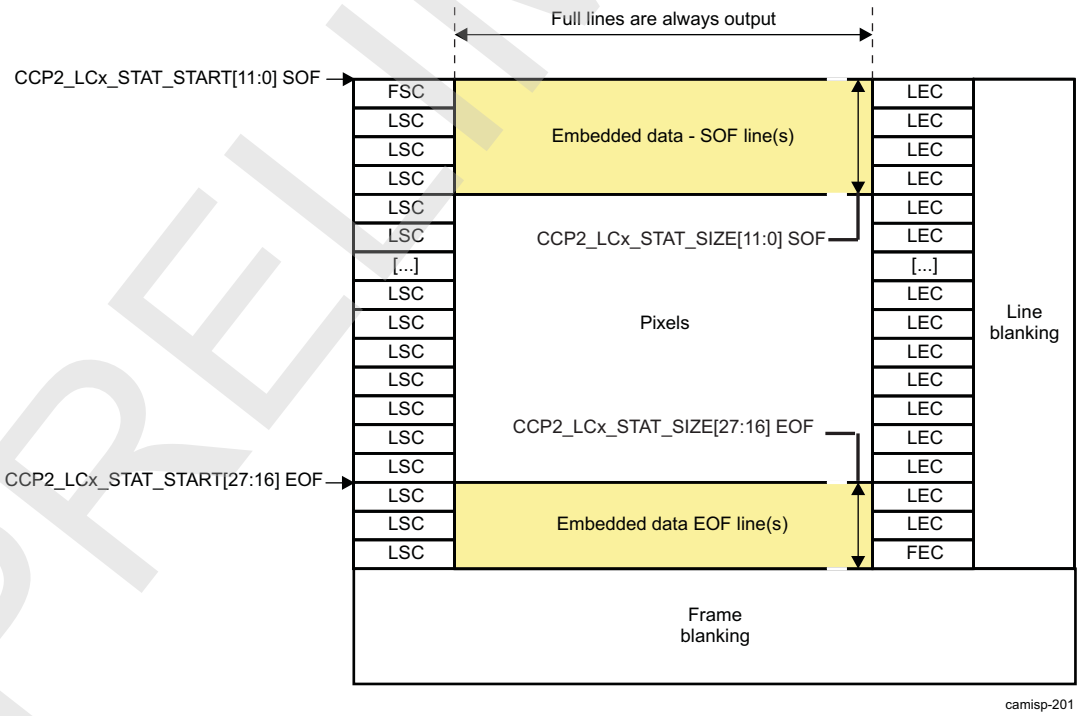
The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The CCP2_LCx_STAT_START register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CSI1/CCP2B frame, CCP2_LCx_STAT_START [11:0] SOF = 0x0.

The CCP2_LCx_STAT_SIZE register enables the setting of the numbers of SOF and EOF status lines. If CCP2_LCx_STAT_SIZE [11:0] SOF = 0x0 and CCP2_LCx_STAT_SIZE [27:16] EOF = 0x0, no status data are output.

Figure 6-105 shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive. Figure 6-105 shows the SOF and EOF region settings.

Figure 6-105. Camera ISP CSI1/CCP2B SOF and EOF Region Settings



The 32-bit destination address of the SOF status lines is set by the CCP2_LCx_SOF_ADDR register.

NOTE: The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the CCP2_LCx_EOF_ADDR register.

NOTE: The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The EOF lines are packed together at the destination address.

NOTE: The CSI1/CCP2B receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

6.5.3.19 Camera ISP CSI1/CCP2B Pixel Data Region

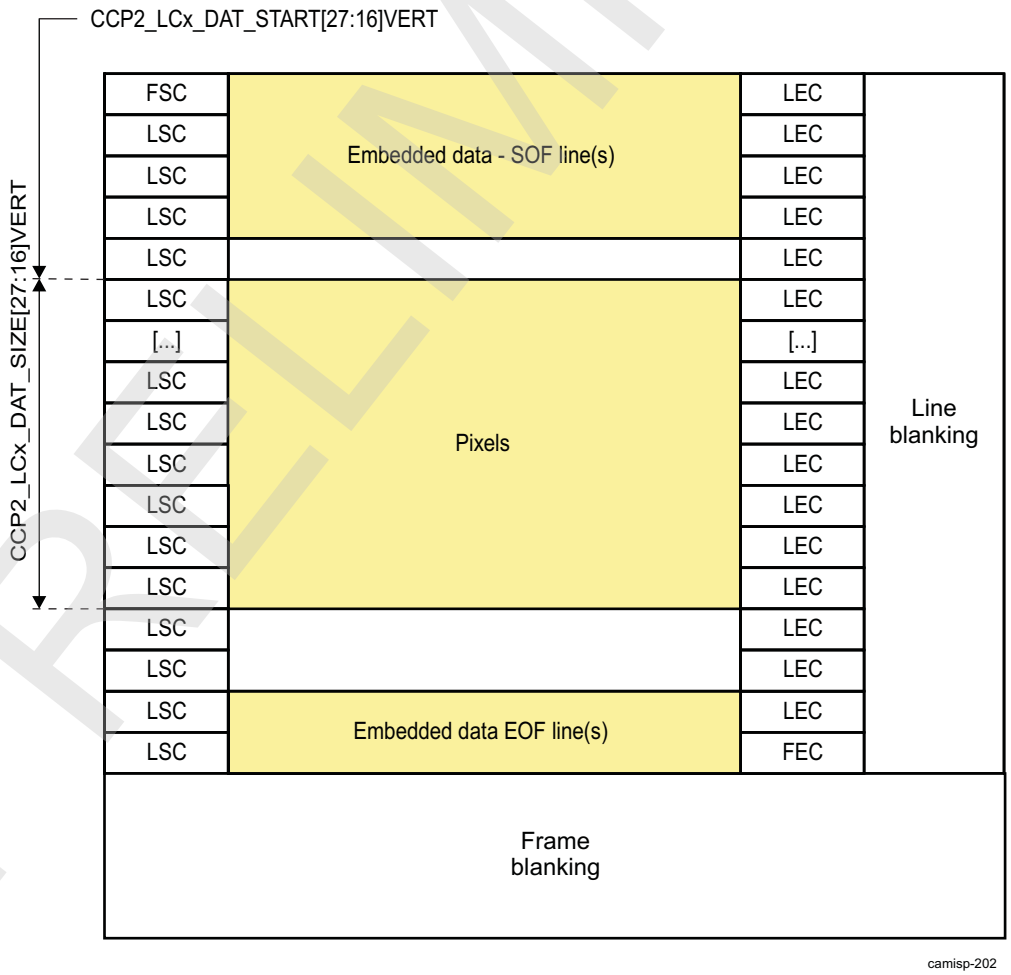
Pixel data can be output to memory or to the Video processing hardware.

The pixel data region covers full lines. The CCP2_LCx_DAT_SIZE register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The CCP2_LCx_DAT_START register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

Figure 6-106 shows the pixel region settings.

Figure 6-106. Camera ISP CSI1/CCP2B Pixel Data Region Settings



The 32-bit destination addresses of the pixel data are set by the CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR registers.

NOTE: The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR registers. It is possible to disable double-buffering by setting up the same address in both registers. The CCP2_LCx_CTRL [17] PING_PONG status bit must be used by the software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the CCP2_LCx_DAT_OFST register. It applies for CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR .

NOTE: The destination pitch must be a multiple of 32 bytes; the address 5 LSBs are ignored.

The use of CCP2_LCx_DAT_OFST is limited to the following destination data formats:

- YUV422 little endian
- YUV422 big endian
- RGB444 + EXP16
- RGB565
- RGB888 + EXP32

For all other data formats, the CCP2_LCx_DAT_OFST register is ignored (equivalent to CCP2_LCx_DAT_OFST = 0x0).

The destination data format is set with the CCP2_LCx_CTRL [7:2] FORMAT bit field.

For the PING frame:

- @Line0 = CCP2_LCx_DAT_PING_ADDR
- @Line1 = @Line0 + CCP2_LCx_DAT_OFST
- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

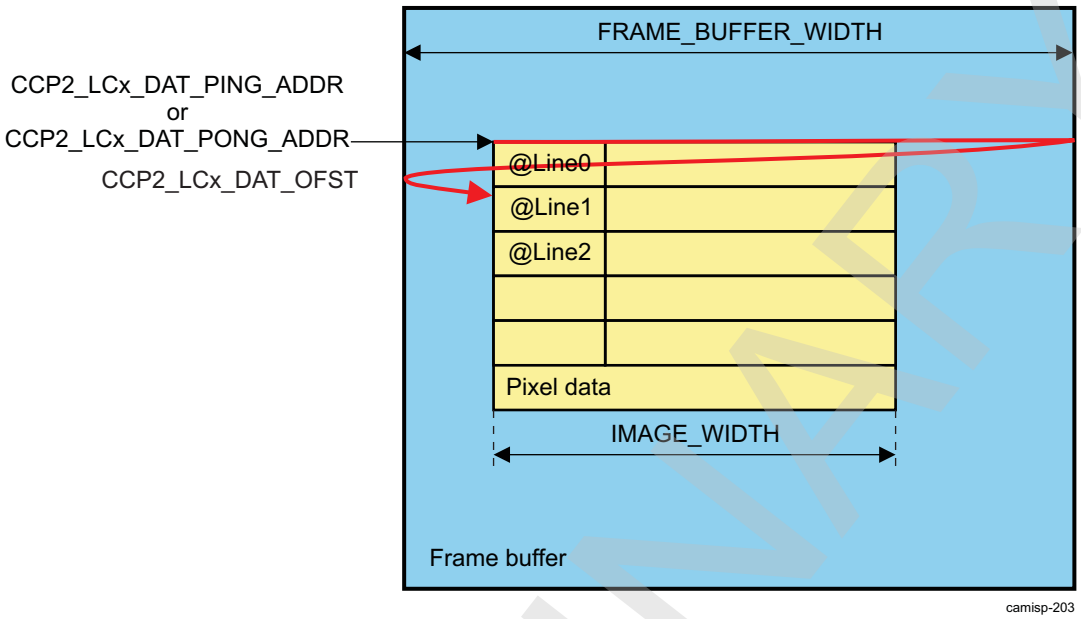
For the PONG frame:

- @Line0 = CCP2_LCx_DAT_PONG_ADDR
- @Line1 = @Line0 + CCP2_LCx_DAT_OFST
- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

When CCP2_LCx_DAT_OFST = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, CCP2_LCx_DAT_OFST = FRAME_BUFFER_WIDTH. Figure 6-107 shows the pixel data settings.

Figure 6-107. Camera ISP CSI1/CCP2B Pixel Data Destination Settings



6.5.3.20 Camera ISP CSI1/CCP2B Memory Read Channel

6.5.3.20.1 Camera ISP CSI1/CCP2B Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV422 little-endian format.

6.5.3.20.2 Camera ISP CSI1/CCP2B Read Data from Memory

By default, the memory read channel is disabled. Before the memory read channel can be enabled (CCP2_LCM_CTRL [0] CHAN_EN = 1), all logical channels must be disabled (CCP2_CTRL [0] IF_EN = 0) and required registers must be configured.

When the CCP2_CTRL [3] FRAME bit is set, software must wait until disabling of the physical interface is effective before enabling the memory read channel.

The SBL image data read port is shared by the PREVIEW and CSI1/CCP2B receiver modules. The read port must be affected to the CSI1/CCP2B receiver module by writing 1 to the ISP_CTRL[27] SBL_SHARED_RPORTA bit. The programmer must ensure that the PREVIEW module does not use this port before switching to the CSI1/CCP2B module.

The burst size must be configured to 32 x 64-bit bursts, using the CCP2_LCM_CTRL [7:5] BURST_SIZE register.

Firmware must then configure the source data format, location, and framing. In addition to the CCP2_LCM_HSIZE [11:0] SKIP and CCP2_LCM_HSIZE [27:16] COUNT registers, the firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula:

HWORDS = 4 x ceil(((SKIP + COUNT) x bits_per_pixel)/(8 x 32)) (3)

The CCP2_LCM_SRC_ADDR and CCP2_LCM_SRC_OFST registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries.

Example:

- CCP2_LCM_CTRL [7:5] BURST_SIZE is set to 32 x 64 bits
- CCP2_LCM_HSIZE [11:0] SKIP = 0

- CCP2_LCM_HSIZE [27:16] COUNT = 1000
- CCP2_LCM_CTRL [23] SRC_PACK = YES
- CCP2_LCM_CTRL [18:16] SRC_FORMAT = RAW6
- CCP2_LCM_PREFETCH [13:3] HWORDS = 96 (>=94)

Setting the size to 94 produces the following burst sequence: 32, 32, 16, 8, and 4 (5 interconnect requests). However, when it is set to 96, the burst sequence is 32, 32, and 32 (3 interconnect requests).

By default, only MIPI® CSI1 data formats are supported. To support CCP2 formats, CCP2_CTRL [4] MODE must be set by firmware.

Data is sent to memory when CCP2_LCM_CTRL [2] DST_PORT = 1; otherwise, it is sent to the video port. It is not possible to send data to the video port and memory concurrently. If data are sent to the video port, its clock frequency is selected with the CCP2_CTRL [31:15] FRACDIV bit field. Otherwise, the CCP2_CTRL [31:15] FRACDIV bit field is ignored.

NOTE: In a given scenario where data is sent to the video port and further down to ISP (CCDC and/or RSZ) to be processed, it is possible for CCP2 to stall the image signal processor by feeding too much data to CCDC and/or RSZ. At that time, the CCDC/RSZ FIFO overflow interrupt is raised. To prevent the processor from stalling, the VP clock must be lowered from CCP2_CTRL[31:15] FRACDIV.

The CCP2_LCM_CTRL [4:3] READ_THROTTLE register can be used to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port.

If the memory write port is used, the destination format and address must be configured.

Then the memory channel is enabled by setting CCP2_LCM_CTRL [0] CHAN_EN = 1. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered.

6.5.4 Programming the CSI2 Receiver

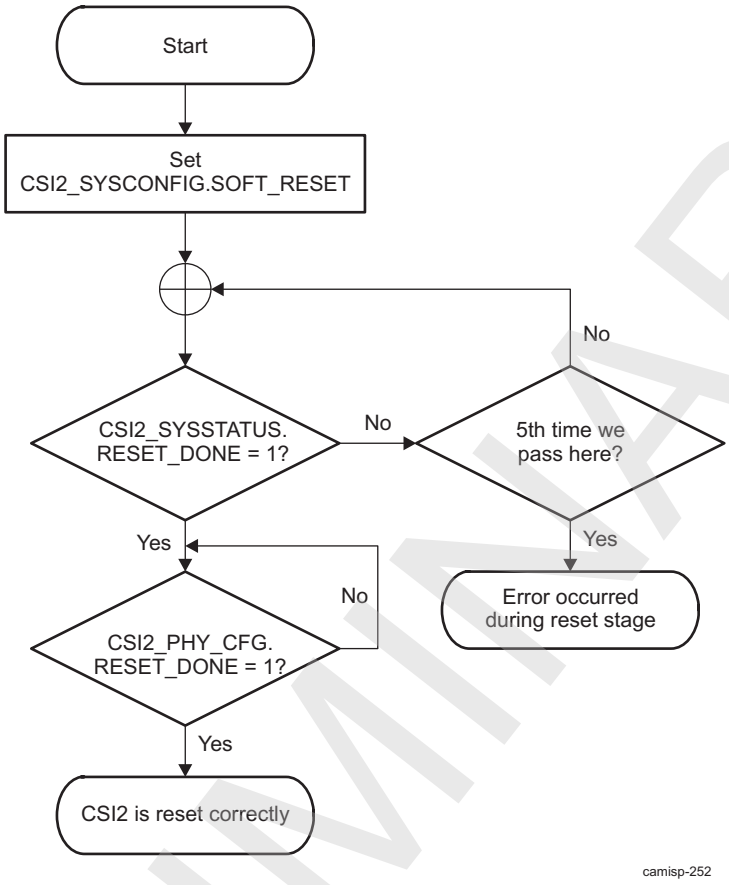
6.5.4.1 Camera ISP CSI2 Enabling the Interface

The CSI2 interface is clocked by CSI2_96_FCLK, which is enabled by setting the PRCM.CM_FCLKEN_CAM[1] EN_CSI2 bit register to 1.

6.5.4.2 Camera ISP CSI2 Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the PHY and has the same effect as a hardware reset. Figure 6-108 shows how to reset the CSI2 globally.

Figure 6-108. Camera ISP CSI2 Receiver Global Reset Flow Chart



NOTE: CSI2_PHY_CFG.RESET_DONE is set to 1 only after the CSI2 receiver, CSI2 PHY's, and external camera sensor are initialized.

NOTE: Before setting the software reset bit to 1 in the CSI2_SYSCONFIG register, the user must have access to a CSI2 receiver register.

NOTE: The CSI2 protocol engine only provides the configuration bus clock when PHY registers are accessed. However, the PHY needs at least 3 configuration bus clock cycles (L4 interconnect clock) to come out of the reset state. Therefore, SW shall perform a dummy read of a PHY register (32 configuration bus clock pulses) to complete the PHY reset sequence.

6.5.4.3 Camera ISP CSI2 Enable Video/Picture Acquisition

To start a video/picture acquisition, perform the following steps:

1. Reset the CSI2 receiver module (see Section 6.5.4.2, *Reset Management*).
2. Configure the module power management: Set the CSI2_SYSCONFIG[13:12] MSTANDBY_MODE bit field to 0x2 so the module tries to enter smart-standby mode during the vertical blanking period. The CSI2_SYSCONFIG[0] AUTO_IDLE bit field keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity
3. Configure the interrupt generation as required using the CSI2_IRQSTATUS and CSI2_IRQENABLE registers. To enable context and/or PHY event reporting, enable the corresponding bit field in the CSI2_IRQENABLE register. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.

4. Configure the PHY interrupt generation as required using the CSI2A_PHY_IRQSTATUS and CSI2_COMPLEXIO1_IRQENABLE registers. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
5. Initialize the PHY (see Section 6.5.2.1, *Camera ISP CSIPHY Initialization for Work With CSI2 Receiver*).
6. Set the CSI2_CTRL[2] ECC_EN bit to 1 to activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).
7. Start the CSI2 receiver by setting the CSI2_CTRL[0] IF_EN bit to 1.
8. Configure the different contexts to be used (up to eight):
   (a) Link the context to a virtual channel and a data type (see Section 6.5.4.7, *Linking a Context to a Virtual Channel and a Data Type*).
   (b) Set the CSI2_CTx_CTRL1[26:23] FEC_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see Section 6.4.3.8, *DMA Engine*.
   (c) Keep the CSI2_CTx_CTRL1[15:8] COUNT bit field and the CSI2_CTx_CTRL1[4] COUNT_UNLOCK bit at their reset values (0x0 and 0, respectively) to capture an infinite number of frames (until the interface or the context is disabled).
   (d) Set the CSI2_CTx_CTRL1[5] CS_EN bit to enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the CSI2_CTx_IRQSTATUS[5] CS_IRQ bit).
   (e) Configure the DMA engine for the current channel:
      - Configure the CSI2_CTx_DAT_PING_ADDR[31:5] ADDR bit field to set the ping frame address in memory.
      - Configure the CSI2_CTx_DAT_PONG_ADDR[31:5] ADDR bit field to set the pong frame address in memory. If not using a double-buffer mechanism, the ping and pong addresses must be equal so that all frames are stored at the same memory address).
      - Set the CSI2_CTx_DAT_OFST[15:5] OFST bit field to 0x0, so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).

   NOTE: Addresses given for PING and PONG frames are virtual addresses. Address translations are made on the camera MMU and on the Circular Buffer. For more information about the camera MMU module, see Chapter 15, *Memory Management Units*.

   (f) Keep the CSI2_CTx_CTRL3[29:16] ALPHA bit field at its reset value (0x0) for RGB padding.
9. Enable the contexts to be used by setting the CSI2_CTx_CTRL1[0] CTX_EN bit to 1.

6.5.4.4 Camera ISP CSI2 Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by writing 0 to the CSI2_CTx_CTRL1[0] CTX_EN bit. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by writing 0 to the CSI2_CTRL[0] IF_EN bit. This can have an immediate effect if the CSI2_CTRL[3] FRAME bit is 0, or it can be effective after all the enabled contexts receive the FEC if the CSI2_CTRL[3] FRAME bit is 1.

6.5.4.5 Camera ISP CSI2 Capture a Finite Number of Frames

The CSI2 receiver module can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the following steps:

1. Write 1 to the CSI2_CTx_CTRL1[4] COUNT_UNLOCK bit to enable a write to the COUNT bit field.
2. Set the bit field to the number of frames the CSI2 receiver must capture. Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
3. Write 0 to the CSI2_CTx_CTRL1[4] COUNT_UNLOCK bit to disable a write to the COUNT bit field.

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. The software reads the COUNT bit field to know how many frames still must be captured.

The COUNT bit can be updated during capture if the COUNT_UNLOCK is set to 1.

6.5.4.6 Camera ISP CSI2 Configure a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the CSI2_CTx_CTRL3[15:0] LINE_NUMBER bit field. The event can be generated once or multiple times per frame, depending on the CSI2_CTx_CTRL1[1] LINE_MODULO bit value:

- If the LINE_MODULO bit = 0, the event is generated when the line number corresponding to the LINE_NUMBER bit field is received.
